- [bpo-27621](https://bugs.python.org/issue?@action=redirect&bpo=27621) [https://bugs.python.org/issue?@action=redirect&bpo=27621]: Put query response validation error messages in the query box itself instead of in a separate messagebox. Redo tests to match. Add Mac OSX refinements. Original patch by Mark Roseman.
- [bpo-27620](https://bugs.python.org/issue?@action=redirect&bpo=27620) [https://bugs.python.org/issue?@action=redirect&bpo=27620]: Escape key now closes Query box as cancelled.
- [bpo-27609](https://bugs.python.org/issue?@action=redirect&bpo=27609) [https://bugs.python.org/issue?@action=redirect&bpo=27609]: IDLE: tab after initial whitespace should tab, not autocomplete. This fixes problem with writing docstrings at least twice indented.
- [bpo-27609](https://bugs.python.org/issue?@action=redirect&bpo=27609) [https://bugs.python.org/issue?@action=redirect&bpo=27609]: Explicitly return None when there are also non-None returns. In a few cases, reverse a condition and eliminate a return.

- [bpo-25507](https://bugs.python.org/issue?@action=redirect&bpo=25507) [https://bugs.python.org/issue?@action=redirect&bpo=25507]: IDLE no longer runs buggy code because of its tkinter imports. Users must include the same imports required to run directly in Python.
- [bpo-27173](https://bugs.python.org/issue?@action=redirect&bpo=27173) [https://bugs.python.org/issue?@action=redirect&bpo=27173]: Add 'IDLE Modern Unix' to the built-in key sets. Make the default key set depend on the platform. Add tests for the changes to the config module.
- [bpo-27452](https://bugs.python.org/issue?@action=redirect&bpo=27452) [https://bugs.python.org/issue?@action=redirect&bpo=27452]: add line counter and crc to IDLE configHandler test dump.

## Tests

- [bpo-25805](https://bugs.python.org/issue?@action=redirect&bpo=25805) [https://bugs.python.org/issue?@action=redirect&bpo=25805]: Skip a test in test\_pkgutil as needed that doesn't work when `__name__ == __main__`. Patch by SilentGhost.
- [bpo-27472](https://bugs.python.org/issue?@action=redirect&bpo=27472) [https://bugs.python.org/issue?@action=redirect&bpo=27472]: Add test.support.unix\_shell as the path to the default shell.
- [bpo-27369](https://bugs.python.org/issue?@action=redirect&bpo=27369) [https://bugs.python.org/issue?@action=redirect&bpo=27369]: In test\_pyexpat, avoid testing an error message detail that changed in Expat 2.2.0.
- [bpo-27594](https://bugs.python.org/issue?@action=redirect&bpo=27594) [https://bugs.python.org/issue?@action=redirect&bpo=27594]: Prevent assertion error when running test\_ast with coverage enabled: ensure code object has a valid first line number. Patch suggested by Ivan Levkivskyi.

## Windows

- [bpo-27647](https://bugs.python.org/issue?@action=redirect&bpo=27647) [https://bugs.python.org/issue?@action=redirect&bpo=27647]: Update bundled Tcl/Tk to 8.6.6.
- [bpo-27610](https://bugs.python.org/issue?@action=redirect&bpo=27610) [https://bugs.python.org/issue?@action=redirect&bpo=27610]: Adds [PEP 514](https://peps.python.org/pep-0514/) [https://peps.python.org/pep-0514/] metadata to Windows installer
- [bpo-27469](https://bugs.python.org/issue?@action=redirect&bpo=27469) [https://bugs.python.org/issue?@action=redirect&bpo=27469]: Adds a shell extension to the launcher so that drag and drop works correctly.

- [bpo-27309](https://bugs.python.org/issue?@action=redirect&bpo=27309) [https://bugs.python.org/issue?@action=redirect&bpo=27309]: Enables proper Windows styles in python[w].exe manifest.

## Build

- [bpo-27713](https://bugs.python.org/issue?@action=redirect&bpo=27713) [https://bugs.python.org/issue?@action=redirect&bpo=27713]: Suppress spurious build warnings when updating importlib's bootstrap files. Patch by Xiang Zhang
- [bpo-25825](https://bugs.python.org/issue?@action=redirect&bpo=25825) [https://bugs.python.org/issue?@action=redirect&bpo=25825]: Correct the references to Modules/python.exp, which is required on AIX. The references were accidentally changed in 3.5.0a1.
- [bpo-27453](https://bugs.python.org/issue?@action=redirect&bpo=27453) [https://bugs.python.org/issue?@action=redirect&bpo=27453]: CPP invocation in configure must use CPPFLAGS. Patch by Chi Hsuan Yen.
- [bpo-27641](https://bugs.python.org/issue?@action=redirect&bpo=27641) [https://bugs.python.org/issue?@action=redirect&bpo=27641]: The configure script now inserts comments into the makefile to prevent the pgen and \_freeze\_importlib executables from being cross-compiled.
- [bpo-26662](https://bugs.python.org/issue?@action=redirect&bpo=26662) [https://bugs.python.org/issue?@action=redirect&bpo=26662]: Set PYTHON\_FOR\_GEN in configure as the Python program to be used for file generation during the build.
- [bpo-10910](https://bugs.python.org/issue?@action=redirect&bpo=10910) [https://bugs.python.org/issue?@action=redirect&bpo=10910]: Avoid C + + compilation errors on FreeBSD and OS X. Also update FreeBSD version checks for the original ctype UTF-8 workaround.

## Python 3.6.0 alpha 3

*Release date: 2016-07-11*

## Security

- [bpo-27278](https://bugs.python.org/issue?@action=redirect&bpo=27278) [https://bugs.python.org/issue?@action=redirect&bpo=27278]: Fix os.urandom() implementation using getrandom() on Linux. Truncate size to INT\_MAX and

loop until we collected enough random bytes, instead of casting a directly `Py_ssize_t` to `int`.

- [bpo-22636](https://bugs.python.org/issue?@action=redirect&bpo=22636) [https://bugs.python.org/issue?@action=redirect&bpo=22636]: Avoid shell injection problems with `ctypes.util.find_library()`.

## Core and Builtins

- [bpo-27473](https://bugs.python.org/issue?@action=redirect&bpo=27473) [https://bugs.python.org/issue?@action=redirect&bpo=27473]: Fixed possible integer overflow in bytes and bytearray concatenations. Patch by Xiang Zhang.
- [bpo-23034](https://bugs.python.org/issue?@action=redirect&bpo=23034) [https://bugs.python.org/issue?@action=redirect&bpo=23034]: The output of a special Python build with defined `COUNT_ALLOCS`, `SHOW_ALLOC_COUNT` or `SHOW_TRACK_COUNT` macros is now off by default. It can be re-enabled using the “-X showalloccount” option. It now outputs to `stderr` instead of `stdout`.
- [bpo-27443](https://bugs.python.org/issue?@action=redirect&bpo=27443) [https://bugs.python.org/issue?@action=redirect&bpo=27443]: `__length_hint__()` of bytearray iterators no longer return a negative integer for a resized bytearray.
- [bpo-27007](https://bugs.python.org/issue?@action=redirect&bpo=27007) [https://bugs.python.org/issue?@action=redirect&bpo=27007]: The `fromhex()` class methods of bytes and bytearray subclasses now return an instance of corresponding subclass.

## Library

- [bpo-26844](https://bugs.python.org/issue?@action=redirect&bpo=26844) [https://bugs.python.org/issue?@action=redirect&bpo=26844]: Fix error message for `imp.find_module()` to refer to ‘path’ instead of ‘name’. Patch by Lev Maximov.
- [bpo-23804](https://bugs.python.org/issue?@action=redirect&bpo=23804) [https://bugs.python.org/issue?@action=redirect&bpo=23804]: Fix SSL zero-length `recv()` calls to not block and not raise an error about unclean EOF.
- [bpo-27466](https://bugs.python.org/issue?@action=redirect&bpo=27466) [https://bugs.python.org/issue?@action=redirect&bpo=27466]: Change time format returned by `http.cookie.time2netscape`, confirming the netscape cookie format and making it consistent with documentation.
- [bpo-21708](https://bugs.python.org/issue?@action=redirect&bpo=21708) [https://bugs.python.org/issue?@action=redirect&bpo=21708]

@action=redirect&bpo=21708]: Deprecated dbm.dumb behavior that differs from common dbm behavior: creating a database in 'r' and 'w' modes and modifying a database in 'r' mode.

- [bpo-26721](https://bugs.python.org/issue?@action=redirect&bpo=26721) [https://bugs.python.org/issue?@action=redirect&bpo=26721]: Change the socketserver.StreamRequestHandler.wfile attribute to implement BufferedIOBase. In particular, the write() method no longer does partial writes.
- [bpo-22115](https://bugs.python.org/issue?@action=redirect&bpo=22115) [https://bugs.python.org/issue?@action=redirect&bpo=22115]: Added methods trace\_add, trace\_remove and trace\_info in the tkinter.Variable class. They replace old methods trace\_variable, trace, trace\_vdelete and trace\_vinfo that use obsolete Tcl commands and might not work in future versions of Tcl. Fixed old tracing methods: trace\_vdelete() with wrong mode no longer break tracing, trace\_vinfo() now always returns a list of pairs of strings, tracing in the "u" mode now works.
- [bpo-26243](https://bugs.python.org/issue?@action=redirect&bpo=26243) [https://bugs.python.org/issue?@action=redirect&bpo=26243]: Only the level argument to zlib.compress() is keyword argument now. The first argument is positional-only.
- [bpo-27038](https://bugs.python.org/issue?@action=redirect&bpo=27038) [https://bugs.python.org/issue?@action=redirect&bpo=27038]: Expose the DirEntry type as os.DirEntry. Code patch by Jelle Zijlstra.
- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Update os.fspath()/PyOS\_FSPath() to check the return value of \_fspath\_() to be either str or bytes.
- [bpo-18726](https://bugs.python.org/issue?@action=redirect&bpo=18726) [https://bugs.python.org/issue?@action=redirect&bpo=18726]: All optional parameters of the dump(), dumps(), load() and loads() functions and JSONEncoder and JSONDecoder class constructors in the json module are now keyword-only.
- [bpo-27319](https://bugs.python.org/issue?@action=redirect&bpo=27319) [https://bugs.python.org/issue?@action=redirect&bpo=27319]: Methods selection\_set(), selection\_add(), selection\_remove() and selection\_toggle() of ttk.TreeView now allow passing multiple items as multiple arguments instead of passing them as a tuple. Deprecated undocumented ability of calling the selection() method with arguments.

- [bpo-27079](https://bugs.python.org/issue?@action=redirect&bpo=27079) [https://bugs.python.org/issue?@action=redirect&bpo=27079]: Fixed curses.ascii functions isblank(), iscntrl() and ispunct().
- [bpo-27294](https://bugs.python.org/issue?@action=redirect&bpo=27294) [https://bugs.python.org/issue?@action=redirect&bpo=27294]: Numerical state in the repr for Tkinter event objects is now represented as a combination of known flags.
- [bpo-27177](https://bugs.python.org/issue?@action=redirect&bpo=27177) [https://bugs.python.org/issue?@action=redirect&bpo=27177]: Match objects in the re module now support index-like objects as group indices. Based on patches by Jeroen Demeyer and Xiang Zhang.
- [bpo-26754](https://bugs.python.org/issue?@action=redirect&bpo=26754) [https://bugs.python.org/issue?@action=redirect&bpo=26754]: Some functions (compile() etc) accepted a filename argument encoded as an iterable of integers. Now only strings and byte-like objects are accepted.
- [bpo-26536](https://bugs.python.org/issue?@action=redirect&bpo=26536) [https://bugs.python.org/issue?@action=redirect&bpo=26536]: socket.ioctl now supports SIO\_LOOPBACK\_FAST\_PATH. Patch by Daniel Stokes.
- [bpo-27048](https://bugs.python.org/issue?@action=redirect&bpo=27048) [https://bugs.python.org/issue?@action=redirect&bpo=27048]: Prevents distutils failing on Windows when environment variables contain non-ASCII characters
- [bpo-27330](https://bugs.python.org/issue?@action=redirect&bpo=27330) [https://bugs.python.org/issue?@action=redirect&bpo=27330]: Fixed possible leaks in the ctypes module.
- [bpo-27238](https://bugs.python.org/issue?@action=redirect&bpo=27238) [https://bugs.python.org/issue?@action=redirect&bpo=27238]: Got rid of bare excepts in the turtle module. Original patch by Jelle Zijlstra.
- [bpo-27122](https://bugs.python.org/issue?@action=redirect&bpo=27122) [https://bugs.python.org/issue?@action=redirect&bpo=27122]: When an exception is raised within the context being managed by a contextlib.ExitStack() and one of the exit stack generators catches and raises it in a chain, do not re-raise the original exception when exiting, let the new chained one through. This avoids the [PEP 479](https://peps.python.org/pep-0479/) [https://peps.python.org/pep-0479/] bug described in issue25782.
- [bpo-16864](https://bugs.python.org/issue?@action=redirect&bpo=16864) [https://bugs.python.org/issue?@action=redirect&bpo=16864]: sqlite3.Cursor.lastrowid now supports REPLACE statement. Initial patch by Alex LordThorsen.
- [bpo-26386](https://bugs.python.org/issue?@action=redirect&bpo=26386) [https://bugs.python.org/issue?@action=redirect&bpo=26386]

- @action=redirect&bpo=26386]: Fixed ttk.TreeView selection operations with item id's containing spaces.
- [bpo-8637](https://bugs.python.org/issue?@action=redirect&bpo=8637) [https://bugs.python.org/issue?@action=redirect&bpo=8637]: Honor a pager set by the env var MANPAGER (in preference to one set by the env var PAGER).
- [bpo-16182](https://bugs.python.org/issue?@action=redirect&bpo=16182) [https://bugs.python.org/issue?@action=redirect&bpo=16182]: Fix various functions in the “readline” module to use the locale encoding, and fix get\_begidx() and get\_endidx() to return code point indexes.
- [bpo-27392](https://bugs.python.org/issue?@action=redirect&bpo=27392) [https://bugs.python.org/issue?@action=redirect&bpo=27392]: Add loop.connect\_accepted\_socket(). Patch by Jim Fulton.

## IDLE

- [bpo-27477](https://bugs.python.org/issue?@action=redirect&bpo=27477) [https://bugs.python.org/issue?@action=redirect&bpo=27477]: IDLE search dialogs now use ttk widgets.
- [bpo-27173](https://bugs.python.org/issue?@action=redirect&bpo=27173) [https://bugs.python.org/issue?@action=redirect&bpo=27173]: Add ‘IDLE Modern Unix’ to the built-in key sets. Make the default key set depend on the platform. Add tests for the changes to the config module.
- [bpo-27452](https://bugs.python.org/issue?@action=redirect&bpo=27452) [https://bugs.python.org/issue?@action=redirect&bpo=27452]: make command line “idle-test > python test\_help.py” work. `_file_` is relative when python is started in the file's directory.
- [bpo-27452](https://bugs.python.org/issue?@action=redirect&bpo=27452) [https://bugs.python.org/issue?@action=redirect&bpo=27452]: add line counter and crc to IDLE configHandler test dump.
- [bpo-27380](https://bugs.python.org/issue?@action=redirect&bpo=27380) [https://bugs.python.org/issue?@action=redirect&bpo=27380]: IDLE: add query.py with base Query dialog and ttk widgets. Module had subclasses SectionName, ModuleName, and HelpSource, which are used to get information from users by configdialog and file = > Load Module. Each subclass has its own validity checks. Using ModuleName allows users to edit bad module names instead of starting over. Add tests and delete the two files combined into the new one.
- [bpo-27372](https://bugs.python.org/issue?@action=redirect&bpo=27372) [https://bugs.python.org/issue?@action=redirect&bpo=27372]: Test\_idle no longer changes the

locale.

- [bpo-27365](https://bugs.python.org/issue?@action=redirect&bpo=27365) [https://bugs.python.org/issue?@action=redirect&bpo=27365]: Allow non-ascii chars in IDLE NEWS.txt, for contributor names.
- [bpo-27245](https://bugs.python.org/issue?@action=redirect&bpo=27245) [https://bugs.python.org/issue?@action=redirect&bpo=27245]: IDLE: Cleanly delete custom themes and key bindings. Previously, when IDLE was started from a console or by import, a cascade of warnings was emitted. Patch by Serhiy Storchaka.
- [bpo-24137](https://bugs.python.org/issue?@action=redirect&bpo=24137) [https://bugs.python.org/issue?@action=redirect&bpo=24137]: Run IDLE, test\_idle, and htest with tkinter default root disabled. Fix code and tests that fail with this restriction. Fix htests to not create a second and redundant root and mainloop.
- [bpo-27310](https://bugs.python.org/issue?@action=redirect&bpo=27310) [https://bugs.python.org/issue?@action=redirect&bpo=27310]: Fix IDLE.app failure to launch on OS X due to vestigial import.

## C API

- [bpo-26754](https://bugs.python.org/issue?@action=redirect&bpo=26754) [https://bugs.python.org/issue?@action=redirect&bpo=26754]: PyUnicode\_FSDecoder() accepted a filename argument encoded as an iterable of integers. Now only strings and byte-like objects are accepted.

## Build

- [bpo-28066](https://bugs.python.org/issue?@action=redirect&bpo=28066) [https://bugs.python.org/issue?@action=redirect&bpo=28066]: Fix the logic that searches build directories for generated include files when building outside the source tree.
- [bpo-27442](https://bugs.python.org/issue?@action=redirect&bpo=27442) [https://bugs.python.org/issue?@action=redirect&bpo=27442]: Expose the Android API level that python was built against, in sysconfig.get\_config\_vars() as 'ANDROID\_API\_LEVEL'.
- [bpo-27434](https://bugs.python.org/issue?@action=redirect&bpo=27434) [https://bugs.python.org/issue?@action=redirect&bpo=27434]: The interpreter that runs the cross-build, found in PATH, must now be of the same feature version (e.g. 3.6) as the source being built.
- [bpo-26930](https://bugs.python.org/issue?@action=redirect&bpo=26930) [https://bugs.python.org/issue?@action=redirect&bpo=26930]

@action=redirect&bpo=26930]: Update Windows builds to use OpenSSL 1.0.2h.

- [bpo-23968](https://bugs.python.org/issue?@action=redirect&bpo=23968) [https://bugs.python.org/issue?@action=redirect&bpo=23968]: Rename the platform directory from plat-\$(MACHDEP) to plat-\$(PLATFORM\_TRIPLET). Rename the config directory (LIBPL) from config-\$(LDVERSION) to config-\$(LDVERSION)-\$(PLATFORM\_TRIPLET). Install the platform specific \_sysconfigdata module into the platform directory and rename it to include the ABIFLAGS.
- Don't use largefile support for GNU/Hurd.

## Tools/Demos

- [bpo-27332](https://bugs.python.org/issue?@action=redirect&bpo=27332) [https://bugs.python.org/issue?@action=redirect&bpo=27332]: Fixed the type of the first argument of module-level functions generated by Argument Clinic. Patch by Petr Viktorin.
- [bpo-27418](https://bugs.python.org/issue?@action=redirect&bpo=27418) [https://bugs.python.org/issue?@action=redirect&bpo=27418]: Fixed Tools/importbench/importbench.py.

## Documentation

- [bpo-19489](https://bugs.python.org/issue?@action=redirect&bpo=19489) [https://bugs.python.org/issue?@action=redirect&bpo=19489]: Moved the search box from the sidebar to the header and footer of each page. Patch by Ammar Askar.
- [bpo-27285](https://bugs.python.org/issue?@action=redirect&bpo=27285) [https://bugs.python.org/issue?@action=redirect&bpo=27285]: Update documentation to reflect the deprecation of `pyvenv` and normalize on the term “virtual environment”. Patch by Steve Piercy.

## Tests

- [bpo-27027](https://bugs.python.org/issue?@action=redirect&bpo=27027) [https://bugs.python.org/issue?@action=redirect&bpo=27027]: Added test.support.is\_android that is True when this is an Android build.

# Python 3.6.0 alpha 2

*Release date: 2016-06-13*

## Security

- [bpo-26556](https://bugs.python.org/issue?@action=redirect&bpo=26556) [https://bugs.python.org/issue?@action=redirect&bpo=26556]: Update expat to 2.1.1, fixes CVE-2015-1283.
- Fix TLS stripping vulnerability in smtplib, CVE-2016-0772. Reported by Team Oststrom.
- [bpo-26839](https://bugs.python.org/issue?@action=redirect&bpo=26839) [https://bugs.python.org/issue?@action=redirect&bpo=26839]: On Linux, `os.urandom()` now calls `getrandom()` with `GRND_NONBLOCK` to fall back on reading `/dev/urandom` if the urandom entropy pool is not initialized yet. Patch written by Colm Buckley.

## Core and Builtins

- [bpo-27095](https://bugs.python.org/issue?@action=redirect&bpo=27095) [https://bugs.python.org/issue?@action=redirect&bpo=27095]: Simplified `MAKE_FUNCTION` and removed `MAKE_CLOSURE` opcodes. Patch by Demur Rumed.
- [bpo-27190](https://bugs.python.org/issue?@action=redirect&bpo=27190) [https://bugs.python.org/issue?@action=redirect&bpo=27190]: Raise `NotSupportedError` if `sqlite3` is older than 3.3.1. Patch by Dave Sawyer.
- [bpo-27286](https://bugs.python.org/issue?@action=redirect&bpo=27286) [https://bugs.python.org/issue?@action=redirect&bpo=27286]: Fixed compiling `BUILD_MAP_UNPACK_WITH_CALL` opcode. Calling function with generalized unpacking (PEP 448) and conflicting keyword names could cause undefined behavior.
- [bpo-27140](https://bugs.python.org/issue?@action=redirect&bpo=27140) [https://bugs.python.org/issue?@action=redirect&bpo=27140]: Added `BUILD_CONST_KEY_MAP` opcode.
- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Add support for `os.PathLike` objects to `open()` (part of [PEP 519](https://peps.python.org/pep-0519/) [https://peps.python.org/pep-0519/]).
- [bpo-27066](https://bugs.python.org/issue?@action=redirect&bpo=27066) [https://bugs.python.org/issue?@action=redirect&bpo=27066]: Fixed `SystemError` if a custom

opener (for open()) returns a negative number without setting an exception.

- [bpo-26983](https://bugs.python.org/issue?@action=redirect&bpo=26983) [https://bugs.python.org/issue?@action=redirect&bpo=26983]: float() now always return an instance of exact float. The deprecation warning is emitted if `_float_` returns an instance of a strict subclass of float. In a future versions of Python this can be an error.
- [bpo-27097](https://bugs.python.org/issue?@action=redirect&bpo=27097) [https://bugs.python.org/issue?@action=redirect&bpo=27097]: Python interpreter is now about 7% faster due to optimized instruction decoding. Based on patch by Demur Rumed.
- [bpo-26647](https://bugs.python.org/issue?@action=redirect&bpo=26647) [https://bugs.python.org/issue?@action=redirect&bpo=26647]: Python interpreter now uses 16-bit wordcode instead of bytecode. Patch by Demur Rumed.
- [bpo-23275](https://bugs.python.org/issue?@action=redirect&bpo=23275) [https://bugs.python.org/issue?@action=redirect&bpo=23275]: Allow assigning to an empty target list in round brackets: `() = iterable`.
- [bpo-27243](https://bugs.python.org/issue?@action=redirect&bpo=27243) [https://bugs.python.org/issue?@action=redirect&bpo=27243]: Update the `__aiter__` protocol: instead of returning an awaitable that resolves to an asynchronous iterator, the asynchronous iterator should be returned directly. Doing the former will trigger a PendingDeprecationWarning.

## Library

- Comment out socket (SO\_REUSEPORT) and posix (O\_SHLOCK, O\_EXLOCK) constants exposed on the API which are not implemented on GNU/Hurd. They would not work at runtime anyway.
- [bpo-27025](https://bugs.python.org/issue?@action=redirect&bpo=27025) [https://bugs.python.org/issue?@action=redirect&bpo=27025]: Generated names for Tkinter widgets are now more meaningful and recognizable.
- [bpo-25455](https://bugs.python.org/issue?@action=redirect&bpo=25455) [https://bugs.python.org/issue?@action=redirect&bpo=25455]: Fixed crashes in repr of recursive ElementTree.Element and functools.partial objects.
- [bpo-27294](https://bugs.python.org/issue?@action=redirect&bpo=27294) [https://bugs.python.org/issue?@action=redirect&bpo=27294]: Improved repr for Tkinter event objects.
- [bpo-20508](https://bugs.python.org/issue?@action=redirect&bpo=20508) [https://bugs.python.org/issue?@action=redirect&bpo=20508]

@action=redirect&bpo=20508]: Improve exception message of IPv{4,6}Network.\_getitem\_. Patch by Gareth Rees.

- [bpo-21386](https://bugs.python.org/issue?@action=redirect&bpo=21386) [https://bugs.python.org/issue?@action=redirect&bpo=21386]: Implement missing IPv4Address.is\_global property. It was documented since 07a5610bae9d. Initial patch by Roger Luethi.
- [bpo-27029](https://bugs.python.org/issue?@action=redirect&bpo=27029) [https://bugs.python.org/issue?@action=redirect&bpo=27029]: Removed deprecated support of universal newlines mode from ZipFile.open().
- [bpo-27030](https://bugs.python.org/issue?@action=redirect&bpo=27030) [https://bugs.python.org/issue?@action=redirect&bpo=27030]: Unknown escapes consisting of ' \ ' and an ASCII letter in regular expressions now are errors. The re.LOCALE flag now can be used only with bytes patterns.
- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Add os.PathLike support to DirEntry (part of [PEP 519](https://peps.python.org/pep-0519/) [https://peps.python.org/pep-0519/]). Initial patch by Jelle Zijlstra.
- [bpo-20900](https://bugs.python.org/issue?@action=redirect&bpo=20900) [https://bugs.python.org/issue?@action=redirect&bpo=20900]: distutils register command now decodes HTTP responses correctly. Initial patch by ingrid.
- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Add os.PathLike support to pathlib, removing its provisional status (part of PEP 519). Initial patch by Dusty Phillips.
- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Add support for os.PathLike objects to os.fsencode() and os.fsdecode() (part of [PEP 519](https://peps.python.org/pep-0519/) [https://peps.python.org/pep-0519/]).
- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Introduce os.PathLike and os.fspath() (part of [PEP 519](https://peps.python.org/pep-0519/) [https://peps.python.org/pep-0519/]).
- A new version of typing.py provides several new classes and features: @overload outside stubs, Reversible, DefaultDict, Text, ContextManager, Type[], NewType(), TYPE\_CHECKING, and numerous bug fixes (note that some of the new features are not yet implemented in mypy or other static analyzers). Also classes for [PEP 492](https://peps.python.org/pep-0492/) [https://peps.python.org/pep-0492/] (Awaitable, AsyncIterable, AsyncIterator) have been added (in fact they made it into 3.5.1 but were never mentioned).

- [bpo-25738](https://bugs.python.org/issue?@action=redirect&bpo=25738) [https://bugs.python.org/issue?@action=redirect&bpo=25738]: Stop `http.server.BaseHTTPRequestHandler.send_error()` from sending a message body for 205 Reset Content. Also, don't send Content header fields in responses that don't have a body. Patch by Susumu Koshihara.
- [bpo-21313](https://bugs.python.org/issue?@action=redirect&bpo=21313) [https://bugs.python.org/issue?@action=redirect&bpo=21313]: Fix the “platform” module to tolerate when `sys.version` contains truncated build information.
- [bpo-23883](https://bugs.python.org/issue?@action=redirect&bpo=23883) [https://bugs.python.org/issue?@action=redirect&bpo=23883]: Added missing APIs to `_all_` to match the documented APIs for the following modules: `cgi`, `mailbox`, `mimetypes`, `plistlib` and `smtpd`. Patches by Jacek Kołodziej.
- [bpo-27164](https://bugs.python.org/issue?@action=redirect&bpo=27164) [https://bugs.python.org/issue?@action=redirect&bpo=27164]: In the `zlib` module, allow decompressing raw Deflate streams with a predefined `zdict`. Based on patch by Xiang Zhang.
- [bpo-24291](https://bugs.python.org/issue?@action=redirect&bpo=24291) [https://bugs.python.org/issue?@action=redirect&bpo=24291]: Fix `wsgiref.simple_server.WSGIRequestHandler` to completely write data to the client. Previously it could do partial writes and truncate data. Also, `wsgiref.handler.ServerHandler` can now handle `stdout` doing partial writes, but this is deprecated.
- [bpo-21272](https://bugs.python.org/issue?@action=redirect&bpo=21272) [https://bugs.python.org/issue?@action=redirect&bpo=21272]: Use `_sysconfigdata.py` to initialize `distutils.sysconfig`.
- [bpo-19611](https://bugs.python.org/issue?@action=redirect&bpo=19611) [https://bugs.python.org/issue?@action=redirect&bpo=19611]: `inspect` now reports the implicit `.0` parameters generated by the compiler for comprehension and generator expression scopes as if they were positional-only parameters called `implicit0`. Patch by Jelle Zijlstra.
- [bpo-26809](https://bugs.python.org/issue?@action=redirect&bpo=26809) [https://bugs.python.org/issue?@action=redirect&bpo=26809]: Add `__all__` to `string`. Patch by Emanuel Barry.
- [bpo-26373](https://bugs.python.org/issue?@action=redirect&bpo=26373) [https://bugs.python.org/issue?@action=redirect&bpo=26373]: `subprocess.Popen.communicate` now correctly ignores `BrokenPipeError` when the child

process dies before `.communicate()` is called in more/all circumstances.

- `signal`, `socket`, and `ssl` module `IntEnum` constant name lookups now return a consistent name for values having multiple names. Ex: `signal.Signals(6)` now refers to itself as `signal.SIGALRM` rather than flipping between that and `signal.SIGIOT` based on the interpreter's hash randomization seed.
- [bpo-27167](https://bugs.python.org/issue?@action=redirect&bpo=27167) [https://bugs.python.org/issue?@action=redirect&bpo=27167]: Clarify the `subprocess.CalledProcessError` error message text when the child process died due to a signal.
- [bpo-25931](https://bugs.python.org/issue?@action=redirect&bpo=25931) [https://bugs.python.org/issue?@action=redirect&bpo=25931]: Don't define `socketserver.Forking*` names on platforms such as Windows that do not support `os.fork()`.
- [bpo-21776](https://bugs.python.org/issue?@action=redirect&bpo=21776) [https://bugs.python.org/issue?@action=redirect&bpo=21776]: `distutils.upload` now correctly handles `HTTPError`. Initial patch by Claudiu Popa.
- [bpo-26526](https://bugs.python.org/issue?@action=redirect&bpo=26526) [https://bugs.python.org/issue?@action=redirect&bpo=26526]: Replace custom parse tree validation in the parser module with a simple DFA validator.
- [bpo-27114](https://bugs.python.org/issue?@action=redirect&bpo=27114) [https://bugs.python.org/issue?@action=redirect&bpo=27114]: Fix `SSLContext._load_windows_store_certs` fails with `PermissionError`
- [bpo-18383](https://bugs.python.org/issue?@action=redirect&bpo=18383) [https://bugs.python.org/issue?@action=redirect&bpo=18383]: Avoid creating duplicate filters when using `filterwarnings` and `simplefilter`. Based on patch by Alex Shkop.
- [bpo-23026](https://bugs.python.org/issue?@action=redirect&bpo=23026) [https://bugs.python.org/issue?@action=redirect&bpo=23026]: `winreg.QueryValueEx()` now return an integer for `REG_QWORD` type.
- [bpo-26741](https://bugs.python.org/issue?@action=redirect&bpo=26741) [https://bugs.python.org/issue?@action=redirect&bpo=26741]: `subprocess.Popen` destructor now emits a `ResourceWarning` warning if the child process is still running.
- [bpo-27056](https://bugs.python.org/issue?@action=redirect&bpo=27056) [https://bugs.python.org/issue?@action=redirect&bpo=27056]: Optimize `pickle.load()` and `pickle.loads()`, up to 10% faster to deserialize a lot of small

objects.

- [bpo-21271](https://bugs.python.org/issue?@action=redirect&bpo=21271) [https://bugs.python.org/issue?@action=redirect&bpo=21271]: New keyword only parameters in `reset_mock` call.

## IDLE

- [bpo-5124](https://bugs.python.org/issue?@action=redirect&bpo=5124) [https://bugs.python.org/issue?@action=redirect&bpo=5124]: Paste with text selected now replaces the selection on X11. This matches how paste works on Windows, Mac, most modern Linux apps, and ttk widgets. Original patch by Serhiy Storchaka.
- [bpo-24750](https://bugs.python.org/issue?@action=redirect&bpo=24750) [https://bugs.python.org/issue?@action=redirect&bpo=24750]: Switch all scrollbars in IDLE to ttk versions. Where needed, minimal tests are added to cover changes.
- [bpo-24759](https://bugs.python.org/issue?@action=redirect&bpo=24759) [https://bugs.python.org/issue?@action=redirect&bpo=24759]: IDLE requires tk 8.5 and availability ttk widgets. Delete now unneeded tk version tests and code for older versions. Add test for IDLE syntax colorizer.
- [bpo-27239](https://bugs.python.org/issue?@action=redirect&bpo=27239) [https://bugs.python.org/issue?@action=redirect&bpo=27239]: `idlelib.macosx.isXyzTk` functions initialize as needed.
- [bpo-27262](https://bugs.python.org/issue?@action=redirect&bpo=27262) [https://bugs.python.org/issue?@action=redirect&bpo=27262]: move Aqua unbinding code, which enable context menus, to macosx.
- [bpo-24759](https://bugs.python.org/issue?@action=redirect&bpo=24759) [https://bugs.python.org/issue?@action=redirect&bpo=24759]: Make clear in `idlelib.idle_test.__init__` that the directory is a private implementation of `test.test_idle` and tool for maintainers.
- [bpo-27196](https://bugs.python.org/issue?@action=redirect&bpo=27196) [https://bugs.python.org/issue?@action=redirect&bpo=27196]: Stop ‘ThemeChanged’ warnings when running IDLE tests. These persisted after other warnings were suppressed in #20567. Apply Serhiy Storchaka’s `update_idletasks` solution to four test files. Record this additional advice in `idle_test/README.txt`
- [bpo-20567](https://bugs.python.org/issue?@action=redirect&bpo=20567) [https://bugs.python.org/issue?@action=redirect&bpo=20567]: Revise `idle_test/README.txt` with advice about avoiding tk warning messages from tests. Apply

advice to several IDLE tests.

- [bpo-24225](https://bugs.python.org/issue?@action=redirect&bpo=24225) [https://bugs.python.org/issue?@action=redirect&bpo=24225]: Update `idlelib/README.txt` with new file names and event handlers.
- [bpo-27156](https://bugs.python.org/issue?@action=redirect&bpo=27156) [https://bugs.python.org/issue?@action=redirect&bpo=27156]: Remove obsolete code not used by IDLE.
- [bpo-27117](https://bugs.python.org/issue?@action=redirect&bpo=27117) [https://bugs.python.org/issue?@action=redirect&bpo=27117]: Make colorizer htest and `turtledemo` work with dark themes. Move code for configuring text widget colors to a new function.
- [bpo-24225](https://bugs.python.org/issue?@action=redirect&bpo=24225) [https://bugs.python.org/issue?@action=redirect&bpo=24225]: Rename many `idlelib/*.py` and `idle_test/test_*.py` files. Edit files to replace old names with new names when the old name referred to the module rather than the class it contained. See the issue and IDLE section in What's New in 3.6 for more.
- [bpo-26673](https://bugs.python.org/issue?@action=redirect&bpo=26673) [https://bugs.python.org/issue?@action=redirect&bpo=26673]: When tk reports font size as 0, change to size 10. Such fonts on Linux prevented the configuration dialog from opening.
- [bpo-21939](https://bugs.python.org/issue?@action=redirect&bpo=21939) [https://bugs.python.org/issue?@action=redirect&bpo=21939]: Add test for IDLE's percolator. Original patch by Saimadhav Heblikar.
- [bpo-21676](https://bugs.python.org/issue?@action=redirect&bpo=21676) [https://bugs.python.org/issue?@action=redirect&bpo=21676]: Add test for IDLE's replace dialog. Original patch by Saimadhav Heblikar.
- [bpo-18410](https://bugs.python.org/issue?@action=redirect&bpo=18410) [https://bugs.python.org/issue?@action=redirect&bpo=18410]: Add test for IDLE's search dialog. Original patch by Westley Martínez.
- [bpo-21703](https://bugs.python.org/issue?@action=redirect&bpo=21703) [https://bugs.python.org/issue?@action=redirect&bpo=21703]: Add test for undo delegator. Patch mostly by Saimadhav Heblikar .
- [bpo-27044](https://bugs.python.org/issue?@action=redirect&bpo=27044) [https://bugs.python.org/issue?@action=redirect&bpo=27044]: Add `ConfigDialog.remove_var_callbacks` to stop memory leaks.
- [bpo-23977](https://bugs.python.org/issue?@action=redirect&bpo=23977) [https://bugs.python.org/issue?@action=redirect&bpo=23977]: Add more asserts to `test_delegator`.

## Documentation

- [bpo-16484](https://bugs.python.org/issue?@action=redirect&bpo=16484) [https://bugs.python.org/issue?@action=redirect&bpo=16484]: Change the default PYTHONDOCS URL to “https:”, and fix the resulting links to use lowercase. Patch by Sean Rodman, test by Kaushik Nadikuditi.
- [bpo-24136](https://bugs.python.org/issue?@action=redirect&bpo=24136) [https://bugs.python.org/issue?@action=redirect&bpo=24136]: Document the new [PEP 448](#) [https://peps.python.org/pep-0448/] unpacking syntax of 3.5.
- [bpo-22558](https://bugs.python.org/issue?@action=redirect&bpo=22558) [https://bugs.python.org/issue?@action=redirect&bpo=22558]: Add remaining doc links to source code for Python-coded modules. Patch by Yoni Lavi.

## Tests

- [bpo-25285](https://bugs.python.org/issue?@action=redirect&bpo=25285) [https://bugs.python.org/issue?@action=redirect&bpo=25285]: regrtest now uses subprocesses when the -j1 command line option is used: each test file runs in a fresh child process. Before, the -j1 option was ignored.
- [bpo-25285](https://bugs.python.org/issue?@action=redirect&bpo=25285) [https://bugs.python.org/issue?@action=redirect&bpo=25285]: Tools/buildbot/test.bat script now uses -j1 by default to run each test file in fresh child process.

## Windows

- [bpo-27064](https://bugs.python.org/issue?@action=redirect&bpo=27064) [https://bugs.python.org/issue?@action=redirect&bpo=27064]: The py.exe launcher now defaults to Python 3. The Windows launcher `py.exe` no longer prefers an installed Python 2 version over Python 3 by default when used interactively.
- [bpo-17500](https://bugs.python.org/issue?@action=redirect&bpo=17500) [https://bugs.python.org/issue?@action=redirect&bpo=17500]: Remove unused and outdated icons. (See also: <https://github.com/python/pythondotorg/issues/945>)

## Build

- [bpo-27229](https://bugs.python.org/issue?@action=redirect&bpo=27229) [https://bugs.python.org/issue?@action=redirect&bpo=27229]: Fix the cross-compiling pgen rule

for in-tree builds. Patch by Xavier de Gaye.

- [bpo-26930](https://bugs.python.org/issue?@action=redirect&bpo=26930) [https://bugs.python.org/issue?@action=redirect&bpo=26930]: Update OS X 10.5 + 32-bit-only installer to build and link with OpenSSL 1.0.2h.

## C API

- [bpo-27186](https://bugs.python.org/issue?@action=redirect&bpo=27186) [https://bugs.python.org/issue?@action=redirect&bpo=27186]: Add the PyOS\_FSPath() function (part of [PEP 519](https://peps.python.org/pep-0519/) [https://peps.python.org/pep-0519/]).
- [bpo-26282](https://bugs.python.org/issue?@action=redirect&bpo=26282) [https://bugs.python.org/issue?@action=redirect&bpo=26282]: PyArg\_ParseTupleAndKeywords() now supports positional-only parameters.

## Tools/Demos

- [bpo-26282](https://bugs.python.org/issue?@action=redirect&bpo=26282) [https://bugs.python.org/issue?@action=redirect&bpo=26282]: Argument Clinic now supports positional-only and keyword parameters in the same function.

# Python 3.6.0 alpha 1

*Release date: 2016-05-16*

## Security

- [bpo-26657](https://bugs.python.org/issue?@action=redirect&bpo=26657) [https://bugs.python.org/issue?@action=redirect&bpo=26657]: Fix directory traversal vulnerability with http.server on Windows. This fixes a regression that was introduced in 3.3.4rc1 and 3.4.0rc1. Based on patch by Philipp Hagemeister.
- [bpo-26313](https://bugs.python.org/issue?@action=redirect&bpo=26313) [https://bugs.python.org/issue?@action=redirect&bpo=26313]: ssl.py\_load\_windows\_store\_certs fails if windows cert store is empty. Patch by Baji.
- [bpo-25939](https://bugs.python.org/issue?@action=redirect&bpo=25939) [https://bugs.python.org/issue?@action=redirect&bpo=25939]: On Windows open the cert store readonly in ssl.enum\_certificates.

## Core and Builtins

- [bpo-20041](https://bugs.python.org/issue?@action=redirect&bpo=20041) [https://bugs.python.org/issue?@action=redirect&bpo=20041]: Fixed TypeError when frame.f\_trace is set to None. Patch by Xavier de Gaye.
- [bpo-26168](https://bugs.python.org/issue?@action=redirect&bpo=26168) [https://bugs.python.org/issue?@action=redirect&bpo=26168]: Fixed possible reflinks in failing Py\_BuildValue() with the “N” format unit.
- [bpo-26991](https://bugs.python.org/issue?@action=redirect&bpo=26991) [https://bugs.python.org/issue?@action=redirect&bpo=26991]: Fix possible reflink when creating a function with annotations.
- [bpo-27039](https://bugs.python.org/issue?@action=redirect&bpo=27039) [https://bugs.python.org/issue?@action=redirect&bpo=27039]: Fixed bytearray.remove() for values greater than 127. Based on patch by Joe Jevnik.
- [bpo-23640](https://bugs.python.org/issue?@action=redirect&bpo=23640) [https://bugs.python.org/issue?@action=redirect&bpo=23640]: int.from\_bytes() no longer bypasses constructors for subclasses.
- [bpo-27005](https://bugs.python.org/issue?@action=redirect&bpo=27005) [https://bugs.python.org/issue?@action=redirect&bpo=27005]: Optimized the float.fromhex() class method for exact float. It is now 2 times faster.
- [bpo-18531](https://bugs.python.org/issue?@action=redirect&bpo=18531) [https://bugs.python.org/issue?@action=redirect&bpo=18531]: Single var-keyword argument of dict subtype was passed unscathed to the C-defined function. Now it is converted to exact dict.
- [bpo-26811](https://bugs.python.org/issue?@action=redirect&bpo=26811) [https://bugs.python.org/issue?@action=redirect&bpo=26811]: gc.get\_objects() no longer contains a broken tuple with NULL pointer.
- [bpo-20120](https://bugs.python.org/issue?@action=redirect&bpo=20120) [https://bugs.python.org/issue?@action=redirect&bpo=20120]: Use RawConfigParser for .pypirc parsing, removing support for interpolation unintentionally added with move to Python 3. Behavior no longer does any interpolation in .pypirc files, matching behavior in Python 2.7 and Setuptools 19.0.
- [bpo-26249](https://bugs.python.org/issue?@action=redirect&bpo=26249) [https://bugs.python.org/issue?@action=redirect&bpo=26249]: Memory functions of the **PyMem\_Malloc()** domain (**PYMEM\_DOMAIN\_MEM**) now use the **pymalloc allocator** rather than system **malloc()**. Applications calling **PyMem\_Malloc()** without holding the GIL can now crash: use **PYTHONMALLOC=debug** environment variable to validate the usage of memory allocators in your application.
- [bpo-26802](https://bugs.python.org/issue?@action=redirect&bpo=26802) [https://bugs.python.org/issue?@action=redirect&bpo=26802]

@action=redirect&bpo=26802]: Optimize function calls only using unpacking like `func(*tuple)` (no other positional argument, no keyword): avoid copying the tuple. Patch written by Joe Jevnik.

- [bpo-26659](https://bugs.python.org/issue?@action=redirect&bpo=26659) [https://bugs.python.org/issue?@action=redirect&bpo=26659]: Make the builtin slice type support cycle collection.
- [bpo-26718](https://bugs.python.org/issue?@action=redirect&bpo=26718) [https://bugs.python.org/issue?@action=redirect&bpo=26718]: `super.__init__` no longer leaks memory if called multiple times. NOTE: A direct call of `super.__init__` is not endorsed!
- [bpo-27138](https://bugs.python.org/issue?@action=redirect&bpo=27138) [https://bugs.python.org/issue?@action=redirect&bpo=27138]: Fix the doc comment for `FileFinder.find_spec()`.
- [bpo-27147](https://bugs.python.org/issue?@action=redirect&bpo=27147) [https://bugs.python.org/issue?@action=redirect&bpo=27147]: Mention [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/] in the `importlib` docs.
- [bpo-25339](https://bugs.python.org/issue?@action=redirect&bpo=25339) [https://bugs.python.org/issue?@action=redirect&bpo=25339]: `PYTHONIOENCODING` now has priority over locale in setting the error handler for stdin and stdout.
- [bpo-26494](https://bugs.python.org/issue?@action=redirect&bpo=26494) [https://bugs.python.org/issue?@action=redirect&bpo=26494]: Fixed crash on iterating exhausting iterators. Affected classes are generic sequence iterators, iterators of str, bytes, bytearray, list, tuple, set, frozenset, dict, `OrderedDict`, corresponding views and `os.scandir()` iterator.
- [bpo-26574](https://bugs.python.org/issue?@action=redirect&bpo=26574) [https://bugs.python.org/issue?@action=redirect&bpo=26574]: Optimize `bytes.replace(b'', b'.')` and `bytearray.replace(b'', b'.')`. Patch written by Josh Snider.
- [bpo-26581](https://bugs.python.org/issue?@action=redirect&bpo=26581) [https://bugs.python.org/issue?@action=redirect&bpo=26581]: If coding cookie is specified multiple times on a line in Python source code file, only the first one is taken to account.
- [bpo-19711](https://bugs.python.org/issue?@action=redirect&bpo=19711) [https://bugs.python.org/issue?@action=redirect&bpo=19711]: Add tests for reloading namespace packages.
- [bpo-21099](https://bugs.python.org/issue?@action=redirect&bpo=21099) [https://bugs.python.org/issue?@action=redirect&bpo=21099]

@action=redirect&bpo=21099]: Switch applicable importlib tests to use [PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/] API.

- [bpo-26563](https://bugs.python.org/issue?@action=redirect&bpo=26563) [https://bugs.python.org/issue?@action=redirect&bpo=26563]: Debug hooks on Python memory allocators now raise a fatal error if functions of the [PyMem\\_Malloc\(\)](#) family are called without holding the GIL.
- [bpo-26564](https://bugs.python.org/issue?@action=redirect&bpo=26564) [https://bugs.python.org/issue?@action=redirect&bpo=26564]: On error, the debug hooks on Python memory allocators now use the [tracemalloc](#) module to get the traceback where a memory block was allocated.
- [bpo-26558](https://bugs.python.org/issue?@action=redirect&bpo=26558) [https://bugs.python.org/issue?@action=redirect&bpo=26558]: The debug hooks on Python memory allocator [PyObject\\_Malloc\(\)](#) now detect when functions are called without holding the GIL.
- [bpo-26516](https://bugs.python.org/issue?@action=redirect&bpo=26516) [https://bugs.python.org/issue?@action=redirect&bpo=26516]: Add [PYTHONMALLOC](#) environment variable to set the Python memory allocators and/or install debug hooks.
- [bpo-26516](https://bugs.python.org/issue?@action=redirect&bpo=26516) [https://bugs.python.org/issue?@action=redirect&bpo=26516]: The [PyMem\\_SetupDebugHooks\(\)](#) function can now also be used on Python compiled in release mode.
- [bpo-26516](https://bugs.python.org/issue?@action=redirect&bpo=26516) [https://bugs.python.org/issue?@action=redirect&bpo=26516]: The [PYTHONMALLOCSTATS](#) environment variable can now also be used on Python compiled in release mode. It now has no effect if set to an empty string.
- [bpo-26516](https://bugs.python.org/issue?@action=redirect&bpo=26516) [https://bugs.python.org/issue?@action=redirect&bpo=26516]: In debug mode, debug hooks are now also installed on Python memory allocators when Python is configured without pymalloc.
- [bpo-26464](https://bugs.python.org/issue?@action=redirect&bpo=26464) [https://bugs.python.org/issue?@action=redirect&bpo=26464]: Fix str.translate() when string is ASCII and first replacements removes character, but next replacement uses a non-ASCII character or a string longer than 1 character. Regression introduced in Python 3.5.0.
- [bpo-22836](https://bugs.python.org/issue?@action=redirect&bpo=22836) [https://bugs.python.org/issue?@action=redirect&bpo=22836]: Ensure exception reports from PyErr\_Display() and PyErr\_WriteUnraisable() are sensible

even when formatting them produces secondary errors. This affects the reports produced by `sys._excepthook_()` and when `_del_()` raises an exception.

- [bpo-26302](https://bugs.python.org/issue?@action=redirect&bpo=26302) [https://bugs.python.org/issue?@action=redirect&bpo=26302]: Correct behavior to reject comma as a legal character for cookie names.
- [bpo-26136](https://bugs.python.org/issue?@action=redirect&bpo=26136) [https://bugs.python.org/issue?@action=redirect&bpo=26136]: Upgrade the warning when a generator raises `StopIteration` from `PendingDeprecationWarning` to `DeprecationWarning`. Patch by Anish Shah.
- [bpo-26204](https://bugs.python.org/issue?@action=redirect&bpo=26204) [https://bugs.python.org/issue?@action=redirect&bpo=26204]: The compiler now ignores all constant statements: `bytes`, `str`, `int`, `float`, `complex`, `name` constants (`None`, `False`, `True`), `Ellipsis` and `ast.Constant`; not only `str` and `int`. For example, `1.0` is now ignored in `def f(): 1.0`.
- [bpo-4806](https://bugs.python.org/issue?@action=redirect&bpo=4806) [https://bugs.python.org/issue?@action=redirect&bpo=4806]: Avoid masking the original `TypeError` exception when using `star (*)` unpacking in function calls. Based on patch by Hagen Fürstenau and Daniel Urban.
- [bpo-26146](https://bugs.python.org/issue?@action=redirect&bpo=26146) [https://bugs.python.org/issue?@action=redirect&bpo=26146]: Add a new kind of AST node: `ast.Constant`. It can be used by external AST optimizers, but the compiler does not emit directly such node.
- [bpo-23601](https://bugs.python.org/issue?@action=redirect&bpo=23601) [https://bugs.python.org/issue?@action=redirect&bpo=23601]: Sped-up allocation of dict key objects by using Python's small object allocator. (Contributed by Julian Taylor.)
- [bpo-18018](https://bugs.python.org/issue?@action=redirect&bpo=18018) [https://bugs.python.org/issue?@action=redirect&bpo=18018]: `Import` raises `ImportError` instead of `SystemError` if a relative import is attempted without a known parent package.
- [bpo-25843](https://bugs.python.org/issue?@action=redirect&bpo=25843) [https://bugs.python.org/issue?@action=redirect&bpo=25843]: When compiling code, don't merge constants if they are equal but have a different types. For example, `f1, f2 = lambda: 1, lambda: 1.0` is now correctly compiled to two different functions: `f1()` returns `1(int)` and `f2()` returns `1.0(float)`, even if `1` and `1.0` are equal.

- [bpo-26107](https://bugs.python.org/issue?@action=redirect&bpo=26107) [https://bugs.python.org/issue?@action=redirect&bpo=26107]: The format of the `co_lnotab` attribute of code objects changes to support negative line number delta.
- [bpo-26154](https://bugs.python.org/issue?@action=redirect&bpo=26154) [https://bugs.python.org/issue?@action=redirect&bpo=26154]: Add a new private `_PyThreadState_UncheckedGet()` function to get the current Python thread state, but don't issue a fatal error if it is NULL. This new function must be used instead of accessing directly the `_PyThreadState_Current` variable. The variable is no more exposed since Python 3.5.1 to hide the exact implementation of atomic C types, to avoid compiler issues.
- [bpo-25791](https://bugs.python.org/issue?@action=redirect&bpo=25791) [https://bugs.python.org/issue?@action=redirect&bpo=25791]: If `__package__ != __spec__.parent` or if neither `__package__` or `__spec__` are defined then `ImportWarning` is raised.
- [bpo-22995](https://bugs.python.org/issue?@action=redirect&bpo=22995) [https://bugs.python.org/issue?@action=redirect&bpo=22995]: [UPDATE] Comment out the one of the pickleability tests in `_PyObject_GetState()` due to regressions observed in Cython-based projects.
- [bpo-25961](https://bugs.python.org/issue?@action=redirect&bpo=25961) [https://bugs.python.org/issue?@action=redirect&bpo=25961]: Disallowed null characters in the type name.
- [bpo-25973](https://bugs.python.org/issue?@action=redirect&bpo=25973) [https://bugs.python.org/issue?@action=redirect&bpo=25973]: Fix segfault when an invalid nonlocal statement binds a name starting with two underscores.
- [bpo-22995](https://bugs.python.org/issue?@action=redirect&bpo=22995) [https://bugs.python.org/issue?@action=redirect&bpo=22995]: Instances of extension types with a state that aren't subclasses of list or dict and haven't implemented any pickle-related methods (`__reduce__`, `__reduce_ex__`, `__getnewargs__`, `__getnewargs_ex__`, or `__getstate__`), can no longer be pickled. Including `memoryview`.
- [bpo-20440](https://bugs.python.org/issue?@action=redirect&bpo=20440) [https://bugs.python.org/issue?@action=redirect&bpo=20440]: Massive replacing unsafe attribute setting code with special macro `Py_SETREF`.
- [bpo-25766](https://bugs.python.org/issue?@action=redirect&bpo=25766) [https://bugs.python.org/issue?@action=redirect&bpo=25766]: Special method `__bytes__()` now works in `str` subclasses.

- [bpo-25421](https://bugs.python.org/issue?@action=redirect&bpo=25421) [https://bugs.python.org/issue?@action=redirect&bpo=25421]: `__sizeof__` methods of builtin types now use dynamic basic size. This allows `sys.getsize()` to work correctly with their subclasses with `__slots__` defined.
- [bpo-25709](https://bugs.python.org/issue?@action=redirect&bpo=25709) [https://bugs.python.org/issue?@action=redirect&bpo=25709]: Fixed problem with in-place string concatenation and utf-8 cache.
- [bpo-5319](https://bugs.python.org/issue?@action=redirect&bpo=5319) [https://bugs.python.org/issue?@action=redirect&bpo=5319]: New `Py_FinalizeEx()` API allowing Python to set an exit status of 120 on failure to flush buffered streams.
- [bpo-25485](https://bugs.python.org/issue?@action=redirect&bpo=25485) [https://bugs.python.org/issue?@action=redirect&bpo=25485]: `telnetlib.Telnet` is now a context manager.
- [bpo-24097](https://bugs.python.org/issue?@action=redirect&bpo=24097) [https://bugs.python.org/issue?@action=redirect&bpo=24097]: Fixed crash in `object._reduce_()` if slot name is freed inside `__getattr__`.
- [bpo-24731](https://bugs.python.org/issue?@action=redirect&bpo=24731) [https://bugs.python.org/issue?@action=redirect&bpo=24731]: Fixed crash on converting objects with special methods `__bytes__`, `__trunc__`, and `__float__` returning instances of subclasses of `bytes`, `int`, and `float` to subclasses of `bytes`, `int`, and `float` correspondingly.
- [bpo-25630](https://bugs.python.org/issue?@action=redirect&bpo=25630) [https://bugs.python.org/issue?@action=redirect&bpo=25630]: Fix a possible segfault during argument parsing in functions that accept filesystem paths.
- [bpo-23564](https://bugs.python.org/issue?@action=redirect&bpo=23564) [https://bugs.python.org/issue?@action=redirect&bpo=23564]: Fixed a partially broken sanity check in the `_posixsubprocess` internals regarding how `fds_to_pass` were passed to the child. The bug had no actual impact as `subprocess.py` already avoided it.
- [bpo-25388](https://bugs.python.org/issue?@action=redirect&bpo=25388) [https://bugs.python.org/issue?@action=redirect&bpo=25388]: Fixed tokenizer crash when processing undecodable source code with a null byte.
- [bpo-25462](https://bugs.python.org/issue?@action=redirect&bpo=25462) [https://bugs.python.org/issue?@action=redirect&bpo=25462]: The hash of the key now is calculated only once in most operations in C implementation of `OrderedDict`.
- [bpo-22995](https://bugs.python.org/issue?@action=redirect&bpo=22995) [https://bugs.python.org/issue?@action=redirect&bpo=22995]: Default implementation of `__reduce__` and `__reduce_ex__` now rejects builtin types with not defined `__new__`.

- [bpo-24802](https://bugs.python.org/issue?@action=redirect&bpo=24802) [https://bugs.python.org/issue?@action=redirect&bpo=24802]: Avoid buffer overreads when `int()`, `float()`, `compile()`, `exec()` and `eval()` are passed bytes-like objects. These objects are not necessarily terminated by a null byte, but the functions assumed they were.
- [bpo-25555](https://bugs.python.org/issue?@action=redirect&bpo=25555) [https://bugs.python.org/issue?@action=redirect&bpo=25555]: Fix parser and AST: fill `lineno` and `col_offset` of “arg” node when compiling AST from Python objects.
- [bpo-24726](https://bugs.python.org/issue?@action=redirect&bpo=24726) [https://bugs.python.org/issue?@action=redirect&bpo=24726]: Fixed a crash and leaking NULL in `repr()` of `OrderedDict` that was mutated by direct calls of dict methods.
- [bpo-25449](https://bugs.python.org/issue?@action=redirect&bpo=25449) [https://bugs.python.org/issue?@action=redirect&bpo=25449]: Iterating `OrderedDict` with keys with unstable hash now raises `KeyError` in C implementations as well as in Python implementation.
- [bpo-25395](https://bugs.python.org/issue?@action=redirect&bpo=25395) [https://bugs.python.org/issue?@action=redirect&bpo=25395]: Fixed crash when highly nested `OrderedDict` structures were garbage collected.
- [bpo-25401](https://bugs.python.org/issue?@action=redirect&bpo=25401) [https://bugs.python.org/issue?@action=redirect&bpo=25401]: Optimize `bytes.fromhex()` and `bytearray.fromhex()`: they are now between 2x and 3.5x faster.
- [bpo-25399](https://bugs.python.org/issue?@action=redirect&bpo=25399) [https://bugs.python.org/issue?@action=redirect&bpo=25399]: Optimize `bytearray % args` using the new private `_PyBytesWriter` API. Formatting is now between 2.5 and 5 times faster.
- [bpo-25274](https://bugs.python.org/issue?@action=redirect&bpo=25274) [https://bugs.python.org/issue?@action=redirect&bpo=25274]: `sys.setrecursionlimit()` now raises a `RecursionError` if the new recursion limit is too low depending at the current recursion depth. Modify also the “lower-water mark” formula to make it monotonic. This mark is used to decide when the overflowed flag of the thread state is reset.
- [bpo-24402](https://bugs.python.org/issue?@action=redirect&bpo=24402) [https://bugs.python.org/issue?@action=redirect&bpo=24402]: Fix `input()` to prompt to the redirected stdout when `sys.stdout.fileno()` fails.
- [bpo-25349](https://bugs.python.org/issue?@action=redirect&bpo=25349) [https://bugs.python.org/issue?@action=redirect&bpo=25349]: Optimize `bytes % args` using the

new private `_PyBytesWriter` API. Formatting is now up to 2 times faster.

- [bpo-24806](https://bugs.python.org/issue?@action=redirect&bpo=24806) [https://bugs.python.org/issue?@action=redirect&bpo=24806]: Prevent builtin types that are not allowed to be subclassed from being subclassed through multiple inheritance.
- [bpo-25301](https://bugs.python.org/issue?@action=redirect&bpo=25301) [https://bugs.python.org/issue?@action=redirect&bpo=25301]: The UTF-8 decoder is now up to 15 times as fast for error handlers: `ignore`, `replace` and `surrogateescape`.
- [bpo-24848](https://bugs.python.org/issue?@action=redirect&bpo=24848) [https://bugs.python.org/issue?@action=redirect&bpo=24848]: Fixed a number of bugs in UTF-7 decoding of misformed data.
- [bpo-25267](https://bugs.python.org/issue?@action=redirect&bpo=25267) [https://bugs.python.org/issue?@action=redirect&bpo=25267]: The UTF-8 encoder is now up to 75 times as fast for error handlers: `ignore`, `replace`, `surrogateescape`, `surrogatepass`. Patch co-written with Serhiy Storchaka.
- [bpo-25280](https://bugs.python.org/issue?@action=redirect&bpo=25280) [https://bugs.python.org/issue?@action=redirect&bpo=25280]: Import trace messages emitted in verbose (`-v`) mode are no longer formatted twice.
- [bpo-25227](https://bugs.python.org/issue?@action=redirect&bpo=25227) [https://bugs.python.org/issue?@action=redirect&bpo=25227]: Optimize ASCII and latin1 encoders with the `surrogateescape` error handler: the encoders are now up to 3 times as fast. Initial patch written by Serhiy Storchaka.
- [bpo-25003](https://bugs.python.org/issue?@action=redirect&bpo=25003) [https://bugs.python.org/issue?@action=redirect&bpo=25003]: On Solaris 11.3 or newer, `os.urandom()` now uses the `getrandom()` function instead of the `getentropy()` function. The `getentropy()` function is blocking to generate very good quality entropy, `os.urandom()` doesn't need such high-quality entropy.
- [bpo-9232](https://bugs.python.org/issue?@action=redirect&bpo=9232) [https://bugs.python.org/issue?@action=redirect&bpo=9232]: Modify Python's grammar to allow trailing commas in the argument list of a function declaration. For example, "`def f(*, a = 3): pass`" is now legal. Patch from Mark Dickinson.
- [bpo-24965](https://bugs.python.org/issue?@action=redirect&bpo=24965) [https://bugs.python.org/issue?@action=redirect&bpo=24965]: Implement [PEP 498](https://peps.python.org/pep-0498/) [https://peps.python.org/pep-0498/] "Literal String Interpolation". This allows you to embed expressions inside f-strings, which are

converted to normal strings at run time. Given `x=3`, then `fvalue={x}' == 'value=3'`. Patch by Eric V. Smith.

- [bpo-26478](https://bugs.python.org/issue?@action=redirect&bpo=26478) [https://bugs.python.org/issue?@action=redirect&bpo=26478]: Fix semantic bugs when using binary operators with dictionary views and tuples.
- [bpo-26171](https://bugs.python.org/issue?@action=redirect&bpo=26171) [https://bugs.python.org/issue?@action=redirect&bpo=26171]: Fix possible integer overflow and heap corruption in `zipimporter.get_data()`.
- [bpo-25660](https://bugs.python.org/issue?@action=redirect&bpo=25660) [https://bugs.python.org/issue?@action=redirect&bpo=25660]: Fix TAB key behaviour in REPL with readline.
- [bpo-26288](https://bugs.python.org/issue?@action=redirect&bpo=26288) [https://bugs.python.org/issue?@action=redirect&bpo=26288]: Optimize `PyLong_AsDouble`.
- [bpo-26289](https://bugs.python.org/issue?@action=redirect&bpo=26289) [https://bugs.python.org/issue?@action=redirect&bpo=26289]: Optimize floor and modulo division for single-digit longs. Microbenchmarks show 2-2.5x improvement. Built-in `'divmod'` function is now also ~10% faster. (See also: [bpo-26315](https://bugs.python.org/issue?@action=redirect&bpo=26315) [https://bugs.python.org/issue?@action=redirect&bpo=26315])
- [bpo-25887](https://bugs.python.org/issue?@action=redirect&bpo=25887) [https://bugs.python.org/issue?@action=redirect&bpo=25887]: Raise a `RuntimeError` when a coroutine object is awaited more than once.

## Library

- [bpo-27057](https://bugs.python.org/issue?@action=redirect&bpo=27057) [https://bugs.python.org/issue?@action=redirect&bpo=27057]: Fix `os.set_inheritable()` on Android, `ioctl()` is blocked by SELinux and fails with `EACCESS`. The function now falls back to `fcntl()`. Patch written by Michał Bednarski.
- [bpo-27014](https://bugs.python.org/issue?@action=redirect&bpo=27014) [https://bugs.python.org/issue?@action=redirect&bpo=27014]: Fix infinite recursion using `typing.py`. Thanks to Kalle Tuure!
- [bpo-27031](https://bugs.python.org/issue?@action=redirect&bpo=27031) [https://bugs.python.org/issue?@action=redirect&bpo=27031]: Removed dummy methods in Tkinter widget classes: `tk_menuBar()` and `tk_bindForTraversal()`.
- [bpo-14132](https://bugs.python.org/issue?@action=redirect&bpo=14132) [https://bugs.python.org/issue?@action=redirect&bpo=14132]: Fix `urllib.request` redirect handling when the target only has a query string. Original fix

by Ján Janech.

- [bpo-17214](https://bugs.python.org/issue?@action=redirect&bpo=17214) [https://bugs.python.org/issue?@action=redirect&bpo=17214]: The “urllib.request” module now percent-encodes non-ASCII bytes found in redirect target URLs. Some servers send Location header fields with non-ASCII bytes, but “http.client” requires the request target to be ASCII-encodable, otherwise a UnicodeEncodeError is raised. Based on patch by Christian Heimes.
- [bpo-27033](https://bugs.python.org/issue?@action=redirect&bpo=27033) [https://bugs.python.org/issue?@action=redirect&bpo=27033]: The default value of the decode\_data parameter for smtpd.SMTPChannel and smtpd.SMTPServer constructors is changed to False.
- [bpo-27034](https://bugs.python.org/issue?@action=redirect&bpo=27034) [https://bugs.python.org/issue?@action=redirect&bpo=27034]: Removed deprecated class asynchat.fifo.
- [bpo-26870](https://bugs.python.org/issue?@action=redirect&bpo=26870) [https://bugs.python.org/issue?@action=redirect&bpo=26870]: Added readline.set\_auto\_history(), which can stop entries being automatically added to the history list. Based on patch by Tyler Crompton.
- [bpo-26039](https://bugs.python.org/issue?@action=redirect&bpo=26039) [https://bugs.python.org/issue?@action=redirect&bpo=26039]: zipfile.ZipFile.open() can now be used to write data into a ZIP file, as well as for extracting data. Patch by Thomas Kluyver.
- [bpo-26892](https://bugs.python.org/issue?@action=redirect&bpo=26892) [https://bugs.python.org/issue?@action=redirect&bpo=26892]: Honor debuglevel flag in urllib.request.HTTPHandler. Patch contributed by Chi Hsuan Yen.
- [bpo-22274](https://bugs.python.org/issue?@action=redirect&bpo=22274) [https://bugs.python.org/issue?@action=redirect&bpo=22274]: In the subprocess module, allow stderr to be redirected to stdout even when stdout is not redirected. Patch by Akira Li.
- [bpo-26807](https://bugs.python.org/issue?@action=redirect&bpo=26807) [https://bugs.python.org/issue?@action=redirect&bpo=26807]: mock\_open ‘files’ no longer error on readline at end of file. Patch from Yolanda Robla.
- [bpo-25745](https://bugs.python.org/issue?@action=redirect&bpo=25745) [https://bugs.python.org/issue?@action=redirect&bpo=25745]: Fixed leaking a userptr in curses panel destructor.
- [bpo-26977](https://bugs.python.org/issue?@action=redirect&bpo=26977) [https://bugs.python.org/issue?@action=redirect&bpo=26977]: Removed unnecessary, and ignored, call to sum of squares helper in statistics.pvariance.

- [bpo-26002](https://bugs.python.org/issue?@action=redirect&bpo=26002) [https://bugs.python.org/issue?@action=redirect&bpo=26002]: Use `bisect` in `statistics.median` instead of a linear search. Patch by Upendra Kuma.
- [bpo-25974](https://bugs.python.org/issue?@action=redirect&bpo=25974) [https://bugs.python.org/issue?@action=redirect&bpo=25974]: Make use of new `Decimal.as_integer_ratio()` method in `statistics` module. Patch by Stefan Krah.
- [bpo-26996](https://bugs.python.org/issue?@action=redirect&bpo=26996) [https://bugs.python.org/issue?@action=redirect&bpo=26996]: Add `secrets` module as described in [PEP 506](https://peps.python.org/pep-0506/) [https://peps.python.org/pep-0506/].
- [bpo-26881](https://bugs.python.org/issue?@action=redirect&bpo=26881) [https://bugs.python.org/issue?@action=redirect&bpo=26881]: The `modulefinder` module now supports extended opcode arguments.
- [bpo-23815](https://bugs.python.org/issue?@action=redirect&bpo=23815) [https://bugs.python.org/issue?@action=redirect&bpo=23815]: Fixed crashes related to directly created instances of types in `_tkinter` and `curses.panel` modules.
- [bpo-17765](https://bugs.python.org/issue?@action=redirect&bpo=17765) [https://bugs.python.org/issue?@action=redirect&bpo=17765]: `weakref.ref()` no longer silently ignores keyword arguments. Patch by Georg Brandl.
- [bpo-26873](https://bugs.python.org/issue?@action=redirect&bpo=26873) [https://bugs.python.org/issue?@action=redirect&bpo=26873]: `xmlrpc` now raises `ResponseError` on unsupported type tags instead of silently return incorrect result.
- [bpo-26915](https://bugs.python.org/issue?@action=redirect&bpo=26915) [https://bugs.python.org/issue?@action=redirect&bpo=26915]: The `__contains__` methods in the collections ABCs now check for identity before checking equality. This better matches the behavior of the concrete classes, allows sensible handling of NaNs, and makes it easier to reason about container invariants.
- [bpo-26711](https://bugs.python.org/issue?@action=redirect&bpo=26711) [https://bugs.python.org/issue?@action=redirect&bpo=26711]: Fixed the comparison of `plistlib.Data` with other types.
- [bpo-24114](https://bugs.python.org/issue?@action=redirect&bpo=24114) [https://bugs.python.org/issue?@action=redirect&bpo=24114]: Fix an uninitialized variable in `ctypes.util`. The bug only occurs on SunOS when the `ctypes` implementation searches for the `crle` program. Patch by Xiang Zhang. Tested on SunOS by Kees Bos.
- [bpo-26864](https://bugs.python.org/issue?@action=redirect&bpo=26864) [https://bugs.python.org/issue?@action=redirect&bpo=26864]: In `urllib.request`, change the

proxy bypass host checking against `no_proxy` to be case-insensitive, and to not match unrelated host names that happen to have a bypassed hostname as a suffix. Patch by Xiang Zhang.

- [bpo-24902](https://bugs.python.org/issue?@action=redirect&bpo=24902) [https://bugs.python.org/issue?@action=redirect&bpo=24902]: Print server URL on `http.server` startup. Initial patch by Felix Kaiser.
- [bpo-25788](https://bugs.python.org/issue?@action=redirect&bpo=25788) [https://bugs.python.org/issue?@action=redirect&bpo=25788]: `fileinput.hook_encoded()` now supports an “errors” argument for passing to `open`. Original patch by Joseph Hackman.
- [bpo-26634](https://bugs.python.org/issue?@action=redirect&bpo=26634) [https://bugs.python.org/issue?@action=redirect&bpo=26634]: `recursive_repr()` now sets `_qualname_` of wrapper. Patch by Xiang Zhang.
- [bpo-26804](https://bugs.python.org/issue?@action=redirect&bpo=26804) [https://bugs.python.org/issue?@action=redirect&bpo=26804]: `urllib.request` will prefer `lower_case` proxy environment variables over `UPPER_CASE` or `Mixed_Case` ones. Patch contributed by Hans-Peter Jansen.
- [bpo-26837](https://bugs.python.org/issue?@action=redirect&bpo=26837) [https://bugs.python.org/issue?@action=redirect&bpo=26837]: `assertSequenceEqual()` now correctly outputs non-stringified differing items (like bytes in the `-b` mode). This affects `assertListEqual()` and `assertTupleEqual()`.
- [bpo-26041](https://bugs.python.org/issue?@action=redirect&bpo=26041) [https://bugs.python.org/issue?@action=redirect&bpo=26041]: Remove “will be removed in Python 3.7” from deprecation messages of `platform.dist()` and `platform.linux_distribution()`. Patch by Kumaripaba Miyurusara Athukorala.
- [bpo-26822](https://bugs.python.org/issue?@action=redirect&bpo=26822) [https://bugs.python.org/issue?@action=redirect&bpo=26822]: `itemgetter`, `attrgetter` and `methodcaller` objects no longer silently ignore keyword arguments.
- [bpo-26733](https://bugs.python.org/issue?@action=redirect&bpo=26733) [https://bugs.python.org/issue?@action=redirect&bpo=26733]: Disassembling a class now disassembles class and static methods. Patch by Xiang Zhang.
- [bpo-26801](https://bugs.python.org/issue?@action=redirect&bpo=26801) [https://bugs.python.org/issue?@action=redirect&bpo=26801]: Fix error handling in `shutil.get_terminal_size()`, catch `AttributeError` instead of `NameError`. Patch written by Emanuel Barry.
- [bpo-24838](https://bugs.python.org/issue?@action=redirect&bpo=24838) [https://bugs.python.org/issue?@action=redirect&bpo=24838]

@action=redirect&bpo=24838]: tarfile's ustar and gnu formats now correctly calculate name and link field limits for multibyte character encodings like utf-8.

- [bpo-26717](https://bugs.python.org/issue?@action=redirect&bpo=26717) [https://bugs.python.org/issue?@action=redirect&bpo=26717]: Stop encoding Latin-1-ized WSGI paths with UTF-8. Patch by Anthony Sottile.
- [bpo-26782](https://bugs.python.org/issue?@action=redirect&bpo=26782) [https://bugs.python.org/issue?@action=redirect&bpo=26782]: Add STARTUPINFO to subprocess.\_all\_ on Windows.
- [bpo-26404](https://bugs.python.org/issue?@action=redirect&bpo=26404) [https://bugs.python.org/issue?@action=redirect&bpo=26404]: Add context manager to socketserver. Patch by Aviv Palivoda.
- [bpo-26735](https://bugs.python.org/issue?@action=redirect&bpo=26735) [https://bugs.python.org/issue?@action=redirect&bpo=26735]: Fix `os.urandom()` on Solaris 11.3 and newer when reading more than 1,024 bytes: call `getrandom()` multiple times with a limit of 1024 bytes per call.
- [bpo-26585](https://bugs.python.org/issue?@action=redirect&bpo=26585) [https://bugs.python.org/issue?@action=redirect&bpo=26585]: Eliminate `http.server.quote_html()` and use `html.escape(quote=False)`. Patch by Xiang Zhang.
- [bpo-26685](https://bugs.python.org/issue?@action=redirect&bpo=26685) [https://bugs.python.org/issue?@action=redirect&bpo=26685]: Raise `OSError` if closing a socket fails.
- [bpo-16329](https://bugs.python.org/issue?@action=redirect&bpo=16329) [https://bugs.python.org/issue?@action=redirect&bpo=16329]: Add `.webm` to `mimetypes.types_map`. Patch by Giampaolo Rodola'.
- [bpo-13952](https://bugs.python.org/issue?@action=redirect&bpo=13952) [https://bugs.python.org/issue?@action=redirect&bpo=13952]: Add `.csv` to `mimetypes.types_map`. Patch by Geoff Wilson.
- [bpo-26587](https://bugs.python.org/issue?@action=redirect&bpo=26587) [https://bugs.python.org/issue?@action=redirect&bpo=26587]: the `site` module now allows `.pth` files to specify files to be added to `sys.path` (e.g. zip files).
- [bpo-25609](https://bugs.python.org/issue?@action=redirect&bpo=25609) [https://bugs.python.org/issue?@action=redirect&bpo=25609]: Introduce `contextlib.AbstractContextManager` and `typing.ContextManager`.
- [bpo-26709](https://bugs.python.org/issue?@action=redirect&bpo=26709) [https://bugs.python.org/issue?@action=redirect&bpo=26709]: Fixed Y2038 problem in loading binary PLists.

- [bpo-23735](https://bugs.python.org/issue?@action=redirect&bpo=23735) [https://bugs.python.org/issue?@action=redirect&bpo=23735]: Handle terminal resizing with Readline 6.3+ by installing our own SIGWINCH handler. Patch by Eric Price.
- [bpo-25951](https://bugs.python.org/issue?@action=redirect&bpo=25951) [https://bugs.python.org/issue?@action=redirect&bpo=25951]: Change SSLSocket.sendall() to return None, as explicitly documented for plain socket objects. Patch by Aviv Palivoda.
- [bpo-26586](https://bugs.python.org/issue?@action=redirect&bpo=26586) [https://bugs.python.org/issue?@action=redirect&bpo=26586]: In http.server, respond with “413 Request header fields too large” if there are too many header fields to parse, rather than killing the connection and raising an unhandled exception. Patch by Xiang Zhang.
- [bpo-26676](https://bugs.python.org/issue?@action=redirect&bpo=26676) [https://bugs.python.org/issue?@action=redirect&bpo=26676]: Added missing XMLPullParser to ElementTree.\_all\_.
- [bpo-22854](https://bugs.python.org/issue?@action=redirect&bpo=22854) [https://bugs.python.org/issue?@action=redirect&bpo=22854]: Change BufferedReader.writable() and BufferedWriter.readable() to always return False.
- [bpo-26492](https://bugs.python.org/issue?@action=redirect&bpo=26492) [https://bugs.python.org/issue?@action=redirect&bpo=26492]: Exhausted iterator of array.array now conforms with the behavior of iterators of other mutable sequences: it lefts exhausted even if iterated array is extended.
- [bpo-26641](https://bugs.python.org/issue?@action=redirect&bpo=26641) [https://bugs.python.org/issue?@action=redirect&bpo=26641]: doctest.DocFileTest and doctest.testfile() now support packages (module splitted into multiple directories) for the package parameter.
- [bpo-25195](https://bugs.python.org/issue?@action=redirect&bpo=25195) [https://bugs.python.org/issue?@action=redirect&bpo=25195]: Fix a regression in mock.MagicMock. \_Call is a subclass of tuple (changeset 3603bae63c13 only works for classes) so we need to implement \_\_ne\_\_ ourselves. Patch by Andrew Plummer.
- [bpo-26644](https://bugs.python.org/issue?@action=redirect&bpo=26644) [https://bugs.python.org/issue?@action=redirect&bpo=26644]: Raise ValueError rather than SystemError when a negative length is passed to SSLSocket.recv() or read().
- [bpo-23804](https://bugs.python.org/issue?@action=redirect&bpo=23804) [https://bugs.python.org/issue?@action=redirect&bpo=23804]: Fix SSL recv(0) and read(0) methods to return zero bytes instead of up to 1024.

- [bpo-26616](https://bugs.python.org/issue?@action=redirect&bpo=26616) [https://bugs.python.org/issue?@action=redirect&bpo=26616]: Fixed a bug in `datetime.astimezone()` method.
- [bpo-26637](https://bugs.python.org/issue?@action=redirect&bpo=26637) [https://bugs.python.org/issue?@action=redirect&bpo=26637]: The `importlib` module now emits an `ImportError` rather than a `TypeError` if `__import__()` is tried during the Python shutdown process but `sys.path` is already cleared (set to `None`).
- [bpo-21925](https://bugs.python.org/issue?@action=redirect&bpo=21925) [https://bugs.python.org/issue?@action=redirect&bpo=21925]: `warnings.formatwarning()` now catches exceptions when calling `linecache.getline()` and `tracemalloc.get_object_traceback()` to be able to log `ResourceWarning` emitted late during the Python shutdown process.
- [bpo-23848](https://bugs.python.org/issue?@action=redirect&bpo=23848) [https://bugs.python.org/issue?@action=redirect&bpo=23848]: On Windows, `faulthandler.enable()` now also installs an exception handler to dump the traceback of all Python threads on any Windows exception, not only on UNIX signals (SIGSEGV, SIGFPE, SIGABRT).
- [bpo-26530](https://bugs.python.org/issue?@action=redirect&bpo=26530) [https://bugs.python.org/issue?@action=redirect&bpo=26530]: Add C functions `_PyTraceMalloc_Track()` and `_PyTraceMalloc_Untrack()` to track memory blocks using the `tracemalloc` module. Add `_PyTraceMalloc_GetTraceback()` to get the traceback of an object.
- [bpo-26588](https://bugs.python.org/issue?@action=redirect&bpo=26588) [https://bugs.python.org/issue?@action=redirect&bpo=26588]: The `_tracemalloc` now supports tracing memory allocations of multiple address spaces (domains).
- [bpo-24266](https://bugs.python.org/issue?@action=redirect&bpo=24266) [https://bugs.python.org/issue?@action=redirect&bpo=24266]: Ctrl + C during Readline history search now cancels the search mode when compiled with Readline 7.
- [bpo-26590](https://bugs.python.org/issue?@action=redirect&bpo=26590) [https://bugs.python.org/issue?@action=redirect&bpo=26590]: Implement a safe finalizer for the `_socket.socket` type. It now releases the GIL to close the socket.

- [bpo-18787](https://bugs.python.org/issue?@action=redirect&bpo=18787) [https://bugs.python.org/issue?@action=redirect&bpo=18787]: `spwd.getspnam()` now raises a `PermissionError` if the user doesn't have privileges.
- [bpo-26560](https://bugs.python.org/issue?@action=redirect&bpo=26560) [https://bugs.python.org/issue?@action=redirect&bpo=26560]: Avoid potential `ValueError` in `BaseHandler.start_response`. Initial patch by Peter Inglesby.
- [bpo-26567](https://bugs.python.org/issue?@action=redirect&bpo=26567) [https://bugs.python.org/issue?@action=redirect&bpo=26567]: Add a new function `PyErr_ResourceWarning()` function to pass the destroyed object. Add a `source` attribute to `warnings.WarningMessage`. Add `warnings.showwarnmsg()` which uses `tracemalloc` to get the traceback where source object was allocated.
- [bpo-26569](https://bugs.python.org/issue?@action=redirect&bpo=26569) [https://bugs.python.org/issue?@action=redirect&bpo=26569]: Fix `pyclbr.readmodule()` and `pyclbr.readmodule_ex()` to support importing packages.
- [bpo-26499](https://bugs.python.org/issue?@action=redirect&bpo=26499) [https://bugs.python.org/issue?@action=redirect&bpo=26499]: Account for remaining Content-Length in `HTTPResponse.readline()` and `read1()`. Based on patch by Silent Ghost. Also document that `HTTPResponse` now supports these methods.
- [bpo-25320](https://bugs.python.org/issue?@action=redirect&bpo=25320) [https://bugs.python.org/issue?@action=redirect&bpo=25320]: Handle sockets in directories `unittest` discovery is scanning. Patch from Victor van den Elzen.
- [bpo-16181](https://bugs.python.org/issue?@action=redirect&bpo=16181) [https://bugs.python.org/issue?@action=redirect&bpo=16181]: `cookiejar.http2time()` now returns `None` if year is higher than `datetime.MAXYEAR`.
- [bpo-26513](https://bugs.python.org/issue?@action=redirect&bpo=26513) [https://bugs.python.org/issue?@action=redirect&bpo=26513]: Fixes platform module detection of Windows Server
- [bpo-23718](https://bugs.python.org/issue?@action=redirect&bpo=23718) [https://bugs.python.org/issue?@action=redirect&bpo=23718]: Fixed parsing time in week 0 before Jan 1. Original patch by Tamás Bence Gedai.
- [bpo-26323](https://bugs.python.org/issue?@action=redirect&bpo=26323) [https://bugs.python.org/issue?@action=redirect&bpo=26323]: Add `Mock.assert_called()` and `Mock.assert_called_once()` methods to `unittest.mock`. Patch written by Amit Saha.
- [bpo-20589](https://bugs.python.org/issue?@action=redirect&bpo=20589) [https://bugs.python.org/issue?@action=redirect&bpo=20589]: Invoking `Path.owner()` and

`Path.group()` on Windows now raise `NotImplementedError` instead of `ImportError`.

- [bpo-26177](https://bugs.python.org/issue?@action=redirect&bpo=26177) [https://bugs.python.org/issue?@action=redirect&bpo=26177]: Fixed the `keys()` method for `Canvas` and `Scrollbar` widgets.
- [bpo-15068](https://bugs.python.org/issue?@action=redirect&bpo=15068) [https://bugs.python.org/issue?@action=redirect&bpo=15068]: Got rid of excessive buffering in `fileinput`. The `bufsize` parameter is now deprecated and ignored.
- [bpo-19475](https://bugs.python.org/issue?@action=redirect&bpo=19475) [https://bugs.python.org/issue?@action=redirect&bpo=19475]: Added an optional argument `timespec` to the `datetime.isoformat()` method to choose the precision of the time component.
- [bpo-2202](https://bugs.python.org/issue?@action=redirect&bpo=2202) [https://bugs.python.org/issue?@action=redirect&bpo=2202]: Fix `UnboundLocalError` in `AbstractDigestAuthHandler.get_algorithm_impls`. Initial patch by Mathieu Dupuy.
- [bpo-26167](https://bugs.python.org/issue?@action=redirect&bpo=26167) [https://bugs.python.org/issue?@action=redirect&bpo=26167]: Minimized overhead in `copy.copy()` and `copy.deepcopy()`. Optimized copying and deepcopying `bytearrays`, `NotImplemented`, `slices`, `short lists`, `tuples`, `dicts`, `sets`.
- [bpo-25718](https://bugs.python.org/issue?@action=redirect&bpo=25718) [https://bugs.python.org/issue?@action=redirect&bpo=25718]: Fixed pickling and copying the `accumulate()` iterator with `total is None`.
- [bpo-26475](https://bugs.python.org/issue?@action=redirect&bpo=26475) [https://bugs.python.org/issue?@action=redirect&bpo=26475]: Fixed debugging output for regular expressions with the `(?x)` flag.
- [bpo-26482](https://bugs.python.org/issue?@action=redirect&bpo=26482) [https://bugs.python.org/issue?@action=redirect&bpo=26482]: Allowed pickling recursive dequeues.
- [bpo-26335](https://bugs.python.org/issue?@action=redirect&bpo=26335) [https://bugs.python.org/issue?@action=redirect&bpo=26335]: Make `mmap.write()` return the number of bytes written like other write methods. Patch by Jakub Stasiak.
- [bpo-26457](https://bugs.python.org/issue?@action=redirect&bpo=26457) [https://bugs.python.org/issue?@action=redirect&bpo=26457]: Fixed the `subnets()` methods in IP network classes for the case when resulting prefix length is equal to maximal prefix length. Based on patch by Xiang Zhang.

- [bpo-26385](https://bugs.python.org/issue?@action=redirect&bpo=26385) [https://bugs.python.org/issue?@action=redirect&bpo=26385]: Remove the file if the internal `open()` call in `NamedTemporaryFile()` fails. Patch by Silent Ghost.
- [bpo-26402](https://bugs.python.org/issue?@action=redirect&bpo=26402) [https://bugs.python.org/issue?@action=redirect&bpo=26402]: Fix XML-RPC client to retry when the server shuts down a persistent connection. This was a regression related to the new `http.client.RemoteDisconnected` exception in 3.5.0a4.
- [bpo-25913](https://bugs.python.org/issue?@action=redirect&bpo=25913) [https://bugs.python.org/issue?@action=redirect&bpo=25913]: Leading `<~` is optional now in `base64.a85decode()` with `adobe=True`. Patch by Swati Jaiswal.
- [bpo-26186](https://bugs.python.org/issue?@action=redirect&bpo=26186) [https://bugs.python.org/issue?@action=redirect&bpo=26186]: Remove an invalid type check in `importlib.util.LazyLoader`.
- [bpo-26367](https://bugs.python.org/issue?@action=redirect&bpo=26367) [https://bugs.python.org/issue?@action=redirect&bpo=26367]: `importlib._import_()` raises `ImportError` like builtins `_import_()` when `level` is specified but without an accompanying package specified.
- [bpo-26309](https://bugs.python.org/issue?@action=redirect&bpo=26309) [https://bugs.python.org/issue?@action=redirect&bpo=26309]: In the “socketserver” module, shut down the request (closing the connected socket) when `verify_request()` returns false. Patch by Aviv Palivoda.
- [bpo-23430](https://bugs.python.org/issue?@action=redirect&bpo=23430) [https://bugs.python.org/issue?@action=redirect&bpo=23430]: Change the socketserver module to only catch exceptions raised from a request handler that are derived from `Exception` (instead of `BaseException`). Therefore `SystemExit` and `KeyboardInterrupt` no longer trigger the `handle_error()` method, and will now to stop a single-threaded server.
- [bpo-25995](https://bugs.python.org/issue?@action=redirect&bpo=25995) [https://bugs.python.org/issue?@action=redirect&bpo=25995]: `os.walk()` no longer uses FDs proportional to the tree depth.
- [bpo-25994](https://bugs.python.org/issue?@action=redirect&bpo=25994) [https://bugs.python.org/issue?@action=redirect&bpo=25994]: Added the `close()` method and the support of the context manager protocol for the `os.scandir()` iterator.
- [bpo-23992](https://bugs.python.org/issue?@action=redirect&bpo=23992) [https://bugs.python.org/issue?@action=redirect&bpo=23992]: multiprocessing: make `MapResult`

not fail-fast upon exception.

- [bpo-26243](https://bugs.python.org/issue?@action=redirect&bpo=26243) [https://bugs.python.org/issue?@action=redirect&bpo=26243]: Support keyword arguments to `zlib.compress()`. Patch by Aviv Palivoda.
- [bpo-26117](https://bugs.python.org/issue?@action=redirect&bpo=26117) [https://bugs.python.org/issue?@action=redirect&bpo=26117]: The `os.scandir()` iterator now closes file descriptor not only when the iteration is finished, but when it was failed with error.
- [bpo-25949](https://bugs.python.org/issue?@action=redirect&bpo=25949) [https://bugs.python.org/issue?@action=redirect&bpo=25949]: `__dict__` for an `OrderedDict` instance is now created only when needed.
- [bpo-25911](https://bugs.python.org/issue?@action=redirect&bpo=25911) [https://bugs.python.org/issue?@action=redirect&bpo=25911]: Restored support of bytes paths in `os.walk()` on Windows.
- [bpo-26045](https://bugs.python.org/issue?@action=redirect&bpo=26045) [https://bugs.python.org/issue?@action=redirect&bpo=26045]: Add UTF-8 suggestion to error message when posting a non-Latin-1 string with `http.client`.
- [bpo-26039](https://bugs.python.org/issue?@action=redirect&bpo=26039) [https://bugs.python.org/issue?@action=redirect&bpo=26039]: Added `zipfile.ZipInfo.from_file()` and `zipinfo.ZipInfo.is_dir()`. Patch by Thomas Kluyver.
- [bpo-12923](https://bugs.python.org/issue?@action=redirect&bpo=12923) [https://bugs.python.org/issue?@action=redirect&bpo=12923]: Reset `FancyURLopener`'s redirect counter even if there is an exception. Based on patches by Brian Brazil and Daniel Rocco.
- [bpo-25945](https://bugs.python.org/issue?@action=redirect&bpo=25945) [https://bugs.python.org/issue?@action=redirect&bpo=25945]: Fixed a crash when unpickle the `functools.partial` object with wrong state. Fixed a leak in failed `functools.partial` constructor. “args” and “keywords” attributes of `functools.partial` have now always types tuple and dict correspondingly.
- [bpo-26202](https://bugs.python.org/issue?@action=redirect&bpo=26202) [https://bugs.python.org/issue?@action=redirect&bpo=26202]: `copy.deepcopy()` now correctly copies `range()` objects with non-atomic attributes.
- [bpo-23076](https://bugs.python.org/issue?@action=redirect&bpo=23076) [https://bugs.python.org/issue?@action=redirect&bpo=23076]: `Path.glob()` now raises a `ValueError` if it's called with an invalid pattern. Patch by Thomas Nyberg.
- [bpo-19883](https://bugs.python.org/issue?@action=redirect&bpo=19883) [https://bugs.python.org/issue?@action=redirect&bpo=19883]: Fixed possible integer overflows in `zipimport`.

- [bpo-26227](https://bugs.python.org/issue?@action=redirect&bpo=26227) [https://bugs.python.org/issue?@action=redirect&bpo=26227]: On Windows, `getnameinfo()`, `gethostbyaddr()` and `gethostbyname_ex()` functions of the `socket` module now decode the hostname from the ANSI code page rather than UTF-8.
- [bpo-26099](https://bugs.python.org/issue?@action=redirect&bpo=26099) [https://bugs.python.org/issue?@action=redirect&bpo=26099]: The `site` module now writes an error into `stderr` if `sitecustomize` module can be imported but executing the module raise an `ImportError`. Same change for `usercustomize`.
- [bpo-26147](https://bugs.python.org/issue?@action=redirect&bpo=26147) [https://bugs.python.org/issue?@action=redirect&bpo=26147]: `xmlrpc` now works with strings not encodable with used non-UTF-8 encoding.
- [bpo-25935](https://bugs.python.org/issue?@action=redirect&bpo=25935) [https://bugs.python.org/issue?@action=redirect&bpo=25935]: Garbage collector now breaks reference loops with `OrderedDict`.
- [bpo-16620](https://bugs.python.org/issue?@action=redirect&bpo=16620) [https://bugs.python.org/issue?@action=redirect&bpo=16620]: Fixed `AttributeError` in `msilib.Directory.glob()`.
- [bpo-26013](https://bugs.python.org/issue?@action=redirect&bpo=26013) [https://bugs.python.org/issue?@action=redirect&bpo=26013]: Added compatibility with broken protocol 2 pickles created in old Python 3 versions (3.4.3 and lower).
- [bpo-26129](https://bugs.python.org/issue?@action=redirect&bpo=26129) [https://bugs.python.org/issue?@action=redirect&bpo=26129]: Deprecated accepting non-integers in `grp.getgrgid()`.
- [bpo-25850](https://bugs.python.org/issue?@action=redirect&bpo=25850) [https://bugs.python.org/issue?@action=redirect&bpo=25850]: Use cross-compilation by default for 64-bit Windows.
- [bpo-25822](https://bugs.python.org/issue?@action=redirect&bpo=25822) [https://bugs.python.org/issue?@action=redirect&bpo=25822]: Add docstrings to the fields of `urllib.parse` results. Patch contributed by Swati Jaiswal.
- [bpo-22642](https://bugs.python.org/issue?@action=redirect&bpo=22642) [https://bugs.python.org/issue?@action=redirect&bpo=22642]: Convert trace module option parsing mechanism to `argparse`. Patch contributed by SilentGhost.
- [bpo-24705](https://bugs.python.org/issue?@action=redirect&bpo=24705) [https://bugs.python.org/issue?@action=redirect&bpo=24705]: Fix `sysconfig._parse_makefile` not expanding `${}` vars appearing before `$( )` vars.
- [bpo-26069](https://bugs.python.org/issue?@action=redirect&bpo=26069) [https://bugs.python.org/issue?@action=redirect&bpo=26069]

@action=redirect&bpo=26069]: Remove the deprecated apis in the trace module.

- [bpo-22138](https://bugs.python.org/issue?@action=redirect&bpo=22138) [https://bugs.python.org/issue?@action=redirect&bpo=22138]: Fix mock.patch behavior when patching descriptors. Restore original values after patching. Patch contributed by Sean McCully.
- [bpo-25672](https://bugs.python.org/issue?@action=redirect&bpo=25672) [https://bugs.python.org/issue?@action=redirect&bpo=25672]: In the ssl module, enable the SSL\_MODE\_RELEASE\_BUFFERS mode option if it is safe to do so.
- [bpo-26012](https://bugs.python.org/issue?@action=redirect&bpo=26012) [https://bugs.python.org/issue?@action=redirect&bpo=26012]: Don't traverse into symlinks for \*\* pattern in pathlib.Path.[r]glob().
- [bpo-24120](https://bugs.python.org/issue?@action=redirect&bpo=24120) [https://bugs.python.org/issue?@action=redirect&bpo=24120]: Ignore PermissionError when traversing a tree with pathlib.Path.[r]glob(). Patch by Ulrich Petri.
- [bpo-21815](https://bugs.python.org/issue?@action=redirect&bpo=21815) [https://bugs.python.org/issue?@action=redirect&bpo=21815]: Accept ] characters in the data portion of imap responses, in order to handle the flags with square brackets accepted and produced by servers such as gmail.
- [bpo-25447](https://bugs.python.org/issue?@action=redirect&bpo=25447) [https://bugs.python.org/issue?@action=redirect&bpo=25447]: fileinput now uses sys.stdin as-is if it does not have a buffer attribute (restores backward compatibility).
- [bpo-25971](https://bugs.python.org/issue?@action=redirect&bpo=25971) [https://bugs.python.org/issue?@action=redirect&bpo=25971]: Optimized creating Fractions from floats by 2 times and from Decimals by 3 times.
- [bpo-25802](https://bugs.python.org/issue?@action=redirect&bpo=25802) [https://bugs.python.org/issue?@action=redirect&bpo=25802]: Document as deprecated the remaining implementations of importlib.abc.Loader.load\_module().
- [bpo-25928](https://bugs.python.org/issue?@action=redirect&bpo=25928) [https://bugs.python.org/issue?@action=redirect&bpo=25928]: Add Decimal.as\_integer\_ratio().
- [bpo-25447](https://bugs.python.org/issue?@action=redirect&bpo=25447) [https://bugs.python.org/issue?@action=redirect&bpo=25447]: Copying the lru\_cache() wrapper object now always works, independently from the type of the wrapped object (by returning the original object unchanged).
- [bpo-25768](https://bugs.python.org/issue?@action=redirect&bpo=25768) [https://bugs.python.org/issue?@action=redirect&bpo=25768]

@action=redirect&bpo=25768]: Have the functions in `compileall` return booleans instead of ints and add proper documentation and tests for the return values.

- [bpo-24103](https://bugs.python.org/issue?@action=redirect&bpo=24103) [https://bugs.python.org/issue?@action=redirect&bpo=24103]: Fixed possible use after free in `ElementTree.XMLPullParser`.
- [bpo-25860](https://bugs.python.org/issue?@action=redirect&bpo=25860) [https://bugs.python.org/issue?@action=redirect&bpo=25860]: `os.fwalk()` no longer skips remaining directories when error occurs. Original patch by Samson Lee.
- [bpo-25914](https://bugs.python.org/issue?@action=redirect&bpo=25914) [https://bugs.python.org/issue?@action=redirect&bpo=25914]: Fixed and simplified `OrderedDict.__sizeof__`.
- [bpo-25869](https://bugs.python.org/issue?@action=redirect&bpo=25869) [https://bugs.python.org/issue?@action=redirect&bpo=25869]: Optimized deepcopying `ElementTree`; it is now 20 times faster.
- [bpo-25873](https://bugs.python.org/issue?@action=redirect&bpo=25873) [https://bugs.python.org/issue?@action=redirect&bpo=25873]: Optimized iterating `ElementTree`. Iterating elements `Element.iter()` is now 40% faster, iterating text `Element.itertext()` is now up to 2.5 times faster.
- [bpo-25902](https://bugs.python.org/issue?@action=redirect&bpo=25902) [https://bugs.python.org/issue?@action=redirect&bpo=25902]: Fixed various refcount issues in `ElementTree` iteration.
- [bpo-22227](https://bugs.python.org/issue?@action=redirect&bpo=22227) [https://bugs.python.org/issue?@action=redirect&bpo=22227]: The `TarFile` iterator is reimplemented using generator. This implementation is simpler than using class.
- [bpo-25638](https://bugs.python.org/issue?@action=redirect&bpo=25638) [https://bugs.python.org/issue?@action=redirect&bpo=25638]: Optimized `ElementTree.iterparse()`; it is now 2x faster. Optimized `ElementTree` parsing; it is now 10% faster.
- [bpo-25761](https://bugs.python.org/issue?@action=redirect&bpo=25761) [https://bugs.python.org/issue?@action=redirect&bpo=25761]: Improved detecting errors in broken pickle data.
- [bpo-25717](https://bugs.python.org/issue?@action=redirect&bpo=25717) [https://bugs.python.org/issue?@action=redirect&bpo=25717]: Restore the previous behaviour of tolerating most `fstat()` errors when opening files. This was a regression in 3.5a1, and stopped anonymous temporary files from working in special cases.
- [bpo-24903](https://bugs.python.org/issue?@action=redirect&bpo=24903) [https://bugs.python.org/issue?@action=redirect&bpo=24903]

@action=redirect&bpo=24903]: Fix regression in number of arguments compileall accepts when ‘-d’ is specified. The check on the number of arguments has been dropped completely as it never worked correctly anyway.

- [bpo-25764](https://bugs.python.org/issue?@action=redirect&bpo=25764) [https://bugs.python.org/issue?@action=redirect&bpo=25764]: In the subprocess module, preserve any exception caused by fork() failure when preexec\_fn is used.
- [bpo-25771](https://bugs.python.org/issue?@action=redirect&bpo=25771) [https://bugs.python.org/issue?@action=redirect&bpo=25771]: Tweak the exception message for importlib.util.resolve\_name() when ‘package’ isn’t specified but necessary.
- [bpo-6478](https://bugs.python.org/issue?@action=redirect&bpo=6478) [https://bugs.python.org/issue?@action=redirect&bpo=6478]: \_strptime’s regexp cache now is reset after changing timezone with time.tzset().
- [bpo-14285](https://bugs.python.org/issue?@action=redirect&bpo=14285) [https://bugs.python.org/issue?@action=redirect&bpo=14285]: When executing a package with the “python -m package” option, and package initialization fails, a proper traceback is now reported. The “runpy” module now lets exceptions from package initialization pass back to the caller, rather than raising ImportError.
- [bpo-19771](https://bugs.python.org/issue?@action=redirect&bpo=19771) [https://bugs.python.org/issue?@action=redirect&bpo=19771]: Also in runpy and the “-m” option, omit the irrelevant message “... is a package and cannot be directly executed” if the package could not even be initialized (e.g. due to a bad \*.pyc file).
- [bpo-25177](https://bugs.python.org/issue?@action=redirect&bpo=25177) [https://bugs.python.org/issue?@action=redirect&bpo=25177]: Fixed problem with the mean of very small and very large numbers. As a side effect, statistics.mean and statistics.variance should be significantly faster.
- [bpo-25718](https://bugs.python.org/issue?@action=redirect&bpo=25718) [https://bugs.python.org/issue?@action=redirect&bpo=25718]: Fixed copying object with state with boolean value is false.
- [bpo-10131](https://bugs.python.org/issue?@action=redirect&bpo=10131) [https://bugs.python.org/issue?@action=redirect&bpo=10131]: Fixed deep copying of minidom documents. Based on patch by Marian Ganisin.
- [bpo-7990](https://bugs.python.org/issue?@action=redirect&bpo=7990) [https://bugs.python.org/issue?@action=redirect&bpo=7990]: dir() on ElementTree.Element now lists properties: “tag”, “text”, “tail” and “attrib”. Original patch by Santoso Wijaya.

- [bpo-25725](https://bugs.python.org/issue?@action=redirect&bpo=25725) [https://bugs.python.org/issue?@action=redirect&bpo=25725]: Fixed a reference leak in `pickle.loads()` when unpickling invalid data including tuple instructions.
- [bpo-25663](https://bugs.python.org/issue?@action=redirect&bpo=25663) [https://bugs.python.org/issue?@action=redirect&bpo=25663]: In the Readline completer, avoid listing duplicate global names, and search the global namespace before searching builtins.
- [bpo-25688](https://bugs.python.org/issue?@action=redirect&bpo=25688) [https://bugs.python.org/issue?@action=redirect&bpo=25688]: Fixed file leak in `ElementTree.iterparse()` raising an error.
- [bpo-23914](https://bugs.python.org/issue?@action=redirect&bpo=23914) [https://bugs.python.org/issue?@action=redirect&bpo=23914]: Fixed `SystemError` raised by unpickler on broken pickle data.
- [bpo-25691](https://bugs.python.org/issue?@action=redirect&bpo=25691) [https://bugs.python.org/issue?@action=redirect&bpo=25691]: Fixed crash on deleting `ElementTree.Element` attributes.
- [bpo-25624](https://bugs.python.org/issue?@action=redirect&bpo=25624) [https://bugs.python.org/issue?@action=redirect&bpo=25624]: `ZipFile` now always writes a `ZIP_STORED` header for directory entries. Patch by Dingyuan Wang.
- [bpo-25626](https://bugs.python.org/issue?@action=redirect&bpo=25626) [https://bugs.python.org/issue?@action=redirect&bpo=25626]: Change three `zlib` functions to accept sizes that fit in `Py_ssize_t`, but internally cap those sizes to `UINT_MAX`. This resolves a regression in 3.5 where `GzipFile.read()` failed to read chunks larger than 2 or 4 GiB. The change affects the `zlib.Decompress.decompress()` `max_length` parameter, the `zlib.decompress()` `bufsize` parameter, and the `zlib.Decompress.flush()` `length` parameter.
- [bpo-25583](https://bugs.python.org/issue?@action=redirect&bpo=25583) [https://bugs.python.org/issue?@action=redirect&bpo=25583]: Avoid incorrect errors raised by `os.makedirs(exist_ok=True)` when the OS gives priority to errors such as `EACCES` over `EEXIST`.
- [bpo-25593](https://bugs.python.org/issue?@action=redirect&bpo=25593) [https://bugs.python.org/issue?@action=redirect&bpo=25593]: Change semantics of `EventLoop.stop()` in `asyncio`.
- [bpo-6973](https://bugs.python.org/issue?@action=redirect&bpo=6973) [https://bugs.python.org/issue?@action=redirect&bpo=6973]: When we know a `subprocess.Popen` process has died, do not allow the `send_signal()`, `terminate()`, or `kill()` methods to do anything as they could potentially signal a different process.

- [bpo-23883](https://bugs.python.org/issue?@action=redirect&bpo=23883) [https://bugs.python.org/issue?@action=redirect&bpo=23883]: Added missing APIs to `_all_` to match the documented APIs for the following modules: `calendar`, `csv`, `enum`, `fileinput`, `ftplib`, `logging`, `optparse`, `tarfile`, `threading` and `wave`. Also added a `test.support.check_all_()` helper. Patches by Jacek Kołodziej, Mauro S. M. Rodrigues and Joel Taddei.
- [bpo-25590](https://bugs.python.org/issue?@action=redirect&bpo=25590) [https://bugs.python.org/issue?@action=redirect&bpo=25590]: In the `Readline` completer, only call `getattr()` once per attribute. Also complete names of attributes such as properties and slots which are listed by `dir()` but not yet created on an instance.
- [bpo-25498](https://bugs.python.org/issue?@action=redirect&bpo=25498) [https://bugs.python.org/issue?@action=redirect&bpo=25498]: Fix a crash when garbage-collecting `ctypes` objects created by wrapping a `memoryview`. This was a regression made in 3.5a1. Based on patch by Eryksun.
- [bpo-25584](https://bugs.python.org/issue?@action=redirect&bpo=25584) [https://bugs.python.org/issue?@action=redirect&bpo=25584]: Added “escape” to the `_all_` list in the `glob` module.
- [bpo-25584](https://bugs.python.org/issue?@action=redirect&bpo=25584) [https://bugs.python.org/issue?@action=redirect&bpo=25584]: Fixed recursive `glob()` with patterns starting with `* *`.
- [bpo-25446](https://bugs.python.org/issue?@action=redirect&bpo=25446) [https://bugs.python.org/issue?@action=redirect&bpo=25446]: Fix regression in `smtplib`’s AUTH LOGIN support.
- [bpo-18010](https://bugs.python.org/issue?@action=redirect&bpo=18010) [https://bugs.python.org/issue?@action=redirect&bpo=18010]: Fix the `pydoc` web server’s module search function to handle exceptions from importing packages.
- [bpo-25554](https://bugs.python.org/issue?@action=redirect&bpo=25554) [https://bugs.python.org/issue?@action=redirect&bpo=25554]: Got rid of circular references in regular expression parsing.
- [bpo-18973](https://bugs.python.org/issue?@action=redirect&bpo=18973) [https://bugs.python.org/issue?@action=redirect&bpo=18973]: Command-line interface of the `calendar` module now uses `argparse` instead of `optparse`.
- [bpo-25510](https://bugs.python.org/issue?@action=redirect&bpo=25510) [https://bugs.python.org/issue?@action=redirect&bpo=25510]: `fileinput.FileInput.readline()` now returns `b”` instead of `”` at the end if the `FileInput` was opened with binary mode. Patch by Ryosuke Ito.

- [bpo-25503](https://bugs.python.org/issue?@action=redirect&bpo=25503) [https://bugs.python.org/issue?@action=redirect&bpo=25503]: Fixed inspect.getdoc() for inherited docstrings of properties. Original patch by John Mark Vandenberg.
- [bpo-25515](https://bugs.python.org/issue?@action=redirect&bpo=25515) [https://bugs.python.org/issue?@action=redirect&bpo=25515]: Always use os.urandom as a source of randomness in uuid.uuid4.
- [bpo-21827](https://bugs.python.org/issue?@action=redirect&bpo=21827) [https://bugs.python.org/issue?@action=redirect&bpo=21827]: Fixed textwrap.dedent() for the case when largest common whitespace is a substring of smallest leading whitespace. Based on patch by Robert Li.
- [bpo-25447](https://bugs.python.org/issue?@action=redirect&bpo=25447) [https://bugs.python.org/issue?@action=redirect&bpo=25447]: The lru\_cache() wrapper objects now can be copied and pickled (by returning the original object unchanged).
- [bpo-25390](https://bugs.python.org/issue?@action=redirect&bpo=25390) [https://bugs.python.org/issue?@action=redirect&bpo=25390]: typing: Don't crash on Union[str, Pattern].
- [bpo-25441](https://bugs.python.org/issue?@action=redirect&bpo=25441) [https://bugs.python.org/issue?@action=redirect&bpo=25441]: asyncio: Raise error from drain() when socket is closed.
- [bpo-25410](https://bugs.python.org/issue?@action=redirect&bpo=25410) [https://bugs.python.org/issue?@action=redirect&bpo=25410]: Cleaned up and fixed minor bugs in C implementation of OrderedDict.
- [bpo-25411](https://bugs.python.org/issue?@action=redirect&bpo=25411) [https://bugs.python.org/issue?@action=redirect&bpo=25411]: Improved Unicode support in SMTPHandler through better use of the email package. Thanks to user simon04 for the patch.
- Move the imp module from a PendingDeprecationWarning to DeprecationWarning.
- [bpo-25407](https://bugs.python.org/issue?@action=redirect&bpo=25407) [https://bugs.python.org/issue?@action=redirect&bpo=25407]: Remove mentions of the formatter module being removed in Python 3.6.
- [bpo-25406](https://bugs.python.org/issue?@action=redirect&bpo=25406) [https://bugs.python.org/issue?@action=redirect&bpo=25406]: Fixed a bug in C implementation of OrderedDict.move\_to\_end() that caused segmentation fault or hang in iterating after moving several items to the start of ordered dict.
- [bpo-25382](https://bugs.python.org/issue?@action=redirect&bpo=25382) [https://bugs.python.org/issue?@action=redirect&bpo=25382]: pickletools.dis() now outputs

implicit memo index for the MEMOIZE opcode.

- [bpo-25357](https://bugs.python.org/issue?@action=redirect&bpo=25357) [https://bugs.python.org/issue?@action=redirect&bpo=25357]: Add an optional newline parameter to `binascii.b2a_base64()`. `base64.b64encode()` uses it to avoid a memory copy.
- [bpo-24164](https://bugs.python.org/issue?@action=redirect&bpo=24164) [https://bugs.python.org/issue?@action=redirect&bpo=24164]: Objects that need calling `__new__` with keyword arguments, can now be pickled using pickle protocols older than protocol version 4.
- [bpo-25364](https://bugs.python.org/issue?@action=redirect&bpo=25364) [https://bugs.python.org/issue?@action=redirect&bpo=25364]: `zipfile` now works in threads disabled builds.
- [bpo-25328](https://bugs.python.org/issue?@action=redirect&bpo=25328) [https://bugs.python.org/issue?@action=redirect&bpo=25328]: `smtpd`'s `SMTPChannel` now correctly raises a `ValueError` if both `decode_data` and `enable_SMTPUTF8` are set to `true`.
- [bpo-16099](https://bugs.python.org/issue?@action=redirect&bpo=16099) [https://bugs.python.org/issue?@action=redirect&bpo=16099]: `RobotFileParser` now supports `Crawl-delay` and `Request-rate` extensions. Patch by Nikolay Bogoychev.
- [bpo-25316](https://bugs.python.org/issue?@action=redirect&bpo=25316) [https://bugs.python.org/issue?@action=redirect&bpo=25316]: `distutils` raises `OSError` instead of `DistutilsPlatformError` when `MSVC` is not installed.
- [bpo-25380](https://bugs.python.org/issue?@action=redirect&bpo=25380) [https://bugs.python.org/issue?@action=redirect&bpo=25380]: Fixed protocol for the `STACK_GLOBAL` opcode in `pickletools.opcodes`.
- [bpo-23972](https://bugs.python.org/issue?@action=redirect&bpo=23972) [https://bugs.python.org/issue?@action=redirect&bpo=23972]: Updates `asyncio` `datagram` `create` method allowing `reuseport` and `reuseaddr` socket options to be set prior to binding the socket. Mirroring the existing `asyncio` `create_server` method the `reuseaddr` option for `datagram` sockets defaults to `True` if the O/S is 'posix' (except if the platform is `Cygwin`). Patch by Chris Laws.
- [bpo-25304](https://bugs.python.org/issue?@action=redirect&bpo=25304) [https://bugs.python.org/issue?@action=redirect&bpo=25304]: Add `asyncio.run_coroutine_threadsafe()`. This lets you submit a coroutine to a loop from another thread, returning a `concurrent.futures.Future`. By Vincent Michel.
- [bpo-25232](https://bugs.python.org/issue?@action=redirect&bpo=25232) [https://bugs.python.org/issue?@action=redirect&bpo=25232]: Fix `CGIRequestHandler` to split

the query from the URL at the first question mark (?) rather than the last. Patch from Xiang Zhang.

- [bpo-24657](https://bugs.python.org/issue?@action=redirect&bpo=24657) [https://bugs.python.org/issue?@action=redirect&bpo=24657]: Prevent CGIRequestHandler from collapsing slashes in the query part of the URL as if it were a path. Patch from Xiang Zhang.
- [bpo-25287](https://bugs.python.org/issue?@action=redirect&bpo=25287) [https://bugs.python.org/issue?@action=redirect&bpo=25287]: Don't add crypt.METHOD\_CRYPT to crypt.methods if it's not supported. Check if it is supported, it may not be supported on OpenBSD for example.
- [bpo-23600](https://bugs.python.org/issue?@action=redirect&bpo=23600) [https://bugs.python.org/issue?@action=redirect&bpo=23600]: Default implementation of tzinfo.fromutc() was returning wrong results in some cases.
- [bpo-25203](https://bugs.python.org/issue?@action=redirect&bpo=25203) [https://bugs.python.org/issue?@action=redirect&bpo=25203]: Failed readline.set\_completer\_delims() no longer left the module in inconsistent state.
- [bpo-25011](https://bugs.python.org/issue?@action=redirect&bpo=25011) [https://bugs.python.org/issue?@action=redirect&bpo=25011]: rlcompleter now omits private and special attribute names unless the prefix starts with underscores.
- [bpo-25209](https://bugs.python.org/issue?@action=redirect&bpo=25209) [https://bugs.python.org/issue?@action=redirect&bpo=25209]: rlcompleter now can add a space or a colon after completed keyword.
- [bpo-22241](https://bugs.python.org/issue?@action=redirect&bpo=22241) [https://bugs.python.org/issue?@action=redirect&bpo=22241]: timezone.utc name is now plain 'UTC', not 'UTC-00:00'.
- [bpo-23517](https://bugs.python.org/issue?@action=redirect&bpo=23517) [https://bugs.python.org/issue?@action=redirect&bpo=23517]: fromtimestamp() and utcfromtimestamp() methods of datetime.datetime now round microseconds to nearest with ties going to nearest even integer (ROUND\_HALF\_EVEN), as round(float), instead of rounding towards -Infinity (ROUND\_FLOOR).
- [bpo-23552](https://bugs.python.org/issue?@action=redirect&bpo=23552) [https://bugs.python.org/issue?@action=redirect&bpo=23552]: Timeit now warns when there is substantial (4x) variance between best and worst times. Patch from Serhiy Storchaka.
- [bpo-24633](https://bugs.python.org/issue?@action=redirect&bpo=24633) [https://bugs.python.org/issue?@action=redirect&bpo=24633]: site-packages/README -> README.txt.

- [bpo-24879](https://bugs.python.org/issue?@action=redirect&bpo=24879) [https://bugs.python.org/issue?@action=redirect&bpo=24879]: `help()` and `pydoc` can now list named tuple fields in the order they were defined rather than alphabetically. The ordering is determined by the `_fields` attribute if present.
- [bpo-24874](https://bugs.python.org/issue?@action=redirect&bpo=24874) [https://bugs.python.org/issue?@action=redirect&bpo=24874]: Improve speed of `itertools.cycle()` and make its pickle more compact.
- Fix crash in `itertools.cycle._setstate_()` when the first argument wasn't a list.
- [bpo-20059](https://bugs.python.org/issue?@action=redirect&bpo=20059) [https://bugs.python.org/issue?@action=redirect&bpo=20059]: `urllib.parse` raises `ValueError` on all invalid ports. Patch by Martin Panter.
- [bpo-24360](https://bugs.python.org/issue?@action=redirect&bpo=24360) [https://bugs.python.org/issue?@action=redirect&bpo=24360]: Improve `_repr_` of `argparse.Namespace()` for invalid identifiers. Patch by Matthias Bussonnier.
- [bpo-23426](https://bugs.python.org/issue?@action=redirect&bpo=23426) [https://bugs.python.org/issue?@action=redirect&bpo=23426]: `run_setup` was broken in `distutils`. Patch from Alexander Belopolsky.
- [bpo-13938](https://bugs.python.org/issue?@action=redirect&bpo=13938) [https://bugs.python.org/issue?@action=redirect&bpo=13938]: `2to3` converts `StringTypes` to a tuple. Patch from Mark Hammond.
- [bpo-2091](https://bugs.python.org/issue?@action=redirect&bpo=2091) [https://bugs.python.org/issue?@action=redirect&bpo=2091]: `open()` accepted a 'U' mode string containing '+', but 'U' can only be used with 'r'. Patch from Jeff Balogh and John O'Connor.
- [bpo-8585](https://bugs.python.org/issue?@action=redirect&bpo=8585) [https://bugs.python.org/issue?@action=redirect&bpo=8585]: improved tests for `zipimporter2`. Patch from Mark Lawrence.
- [bpo-18622](https://bugs.python.org/issue?@action=redirect&bpo=18622) [https://bugs.python.org/issue?@action=redirect&bpo=18622]: `unittest.mock.mock_open().reset_mock` would recurse infinitely. Patch from Nicola Palumbo and Laurent De Buyst.
- [bpo-24426](https://bugs.python.org/issue?@action=redirect&bpo=24426) [https://bugs.python.org/issue?@action=redirect&bpo=24426]: Fast searching optimization in regular expressions now works for patterns that starts with capturing groups. Fast searching optimization now can't be disabled at compile time.
- [bpo-23661](https://bugs.python.org/issue?@action=redirect&bpo=23661) [https://bugs.python.org/issue?@action=redirect&bpo=23661]: `unittest.mock` `side_effects` can now

be exceptions again. This was a regression vs Python 3.4.  
Patch from Ignacio Rossi

- [bpo-13248](https://bugs.python.org/issue?@action=redirect&bpo=13248) [https://bugs.python.org/issue?@action=redirect&bpo=13248]: Remove deprecated `inspect.getmoduleinfo` function.
- [bpo-25578](https://bugs.python.org/issue?@action=redirect&bpo=25578) [https://bugs.python.org/issue?@action=redirect&bpo=25578]: Fix (another) memory leak in `SSLSocket.getpeerercer()`.
- [bpo-25530](https://bugs.python.org/issue?@action=redirect&bpo=25530) [https://bugs.python.org/issue?@action=redirect&bpo=25530]: Disable the vulnerable SSLv3 protocol by default when creating `ssl.SSLContext`.
- [bpo-25569](https://bugs.python.org/issue?@action=redirect&bpo=25569) [https://bugs.python.org/issue?@action=redirect&bpo=25569]: Fix memory leak in `SSLSocket.getpeerercert()`.
- [bpo-25471](https://bugs.python.org/issue?@action=redirect&bpo=25471) [https://bugs.python.org/issue?@action=redirect&bpo=25471]: Sockets returned from `accept()` shouldn't appear to be nonblocking.
- [bpo-25319](https://bugs.python.org/issue?@action=redirect&bpo=25319) [https://bugs.python.org/issue?@action=redirect&bpo=25319]: When `threading.Event` is reinitialized, the underlying condition should use a regular lock rather than a recursive lock.
- Skip `getaddrinfo` if host is already resolved. Patch by A. Jesse Jiryu Davis.
- [bpo-26050](https://bugs.python.org/issue?@action=redirect&bpo=26050) [https://bugs.python.org/issue?@action=redirect&bpo=26050]: Add `asyncio.StreamReader.readuntil()` method. Patch by Mapк Копенбегр.
- [bpo-25924](https://bugs.python.org/issue?@action=redirect&bpo=25924) [https://bugs.python.org/issue?@action=redirect&bpo=25924]: Avoid unnecessary serialization of `getaddrinfo(3)` calls on OS X versions 10.5 or higher. Original patch by A. Jesse Jiryu Davis.
- [bpo-26406](https://bugs.python.org/issue?@action=redirect&bpo=26406) [https://bugs.python.org/issue?@action=redirect&bpo=26406]: Avoid unnecessary serialization of `getaddrinfo(3)` calls on current versions of OpenBSD and NetBSD. Patch by A. Jesse Jiryu Davis.
- [bpo-26848](https://bugs.python.org/issue?@action=redirect&bpo=26848) [https://bugs.python.org/issue?@action=redirect&bpo=26848]: Fix `asyncio/subprocess.communicate()` to handle empty input. Patch by Jack O'Connor.
- [bpo-27040](https://bugs.python.org/issue?@action=redirect&bpo=27040) [https://bugs.python.org/issue?@action=redirect&bpo=27040]

@action=redirect&bpo=27040]: Add loop.get\_exception\_handler method

- [bpo-27041](https://bugs.python.org/issue?@action=redirect&bpo=27041) [https://bugs.python.org/issue?@action=redirect&bpo=27041]: asyncio: Add loop.create\_future method

## IDLE

- [bpo-20640](https://bugs.python.org/issue?@action=redirect&bpo=20640) [https://bugs.python.org/issue?@action=redirect&bpo=20640]: Add tests for idlib.configHelpSourceEdit. Patch by Saimadhav Heblikar.
- In the 'IDLE-console differences' section of the IDLE doc, clarify how running with IDLE affects sys.modules and the standard streams.
- [bpo-25507](https://bugs.python.org/issue?@action=redirect&bpo=25507) [https://bugs.python.org/issue?@action=redirect&bpo=25507]: fix incorrect change in IOBinding that prevented printing. Augment IOBinding htest to include all major IOBinding functions.
- [bpo-25905](https://bugs.python.org/issue?@action=redirect&bpo=25905) [https://bugs.python.org/issue?@action=redirect&bpo=25905]: Revert unwanted conversion of ' to ' RIGHT SINGLE QUOTATION MARK in README.txt and open this and NEWS.txt with 'ascii'. Re-encode CREDITS.txt to utf-8 and open it with 'utf-8'.
- [bpo-15348](https://bugs.python.org/issue?@action=redirect&bpo=15348) [https://bugs.python.org/issue?@action=redirect&bpo=15348]: Stop the debugger engine (normally in a user process) before closing the debugger window (running in the IDLE process). This prevents the RuntimeError that were being caught and ignored.
- [bpo-24455](https://bugs.python.org/issue?@action=redirect&bpo=24455) [https://bugs.python.org/issue?@action=redirect&bpo=24455]: Prevent IDLE from hanging when a) closing the shell while the debugger is active (15347); b) closing the debugger with the [X] button (15348); and c) activating the debugger when already active (24455). The patch by Mark Roseman does this by making two changes. 1. Suspend and resume the gui.interaction method with the tcl vwait mechanism intended for this purpose (instead of root.mainloop & .quit). 2. In gui.run, allow any existing interaction to terminate first.
- Change 'The program' to 'Your program' in an IDLE 'kill program?' message to make it clearer that the program

referred to is the currently running user program, not IDLE itself.

- [bpo-24750](https://bugs.python.org/issue?@action=redirect&bpo=24750) [https://bugs.python.org/issue?@action=redirect&bpo=24750]: Improve the appearance of the IDLE editor window status bar. Patch by Mark Roseman.
- [bpo-25313](https://bugs.python.org/issue?@action=redirect&bpo=25313) [https://bugs.python.org/issue?@action=redirect&bpo=25313]: Change the handling of new built-in text color themes to better address the compatibility problem introduced by the addition of IDLE Dark. Consistently use the revised `idleConf.CurrentTheme` everywhere in `idlelib`.
- [bpo-24782](https://bugs.python.org/issue?@action=redirect&bpo=24782) [https://bugs.python.org/issue?@action=redirect&bpo=24782]: Extension configuration is now a tab in the IDLE Preferences dialog rather than a separate dialog. The former tabs are now a sorted list. Patch by Mark Roseman.
- [bpo-22726](https://bugs.python.org/issue?@action=redirect&bpo=22726) [https://bugs.python.org/issue?@action=redirect&bpo=22726]: Re-activate the config dialog help button with some content about the other buttons and the new IDLE Dark theme.
- [bpo-24820](https://bugs.python.org/issue?@action=redirect&bpo=24820) [https://bugs.python.org/issue?@action=redirect&bpo=24820]: IDLE now has an ‘IDLE Dark’ built-in text color theme. It is more or less IDLE Classic inverted, with a cobalt blue background. Strings, comments, keywords, ... are still green, red, orange, ... . To use it with IDLEs released before November 2015, hit the ‘Save as New Custom Theme’ button and enter a new name, such as ‘Custom Dark’. The custom theme will work with any IDLE release, and can be modified.
- [bpo-25224](https://bugs.python.org/issue?@action=redirect&bpo=25224) [https://bugs.python.org/issue?@action=redirect&bpo=25224]: `README.txt` is now an `idlelib` index for IDLE developers and curious users. The previous user content is now in the IDLE doc chapter. ‘IDLE’ now means ‘Integrated Development and Learning Environment’.
- [bpo-24820](https://bugs.python.org/issue?@action=redirect&bpo=24820) [https://bugs.python.org/issue?@action=redirect&bpo=24820]: Users can now set breakpoint colors in Settings -> Custom Highlighting. Original patch by Mark Roseman.
- [bpo-24972](https://bugs.python.org/issue?@action=redirect&bpo=24972) [https://bugs.python.org/issue?@action=redirect&bpo=24972]: Inactive selection background

now matches active selection background, as configured by users, on all systems. Found items are now always highlighted on Windows. Initial patch by Mark Roseman.

- [bpo-24570](https://bugs.python.org/issue?@action=redirect&bpo=24570) [https://bugs.python.org/issue?@action=redirect&bpo=24570]: Idle: make calltip and completion boxes appear on Macs affected by a tk regression. Initial patch by Mark Roseman.
- [bpo-24988](https://bugs.python.org/issue?@action=redirect&bpo=24988) [https://bugs.python.org/issue?@action=redirect&bpo=24988]: Idle ScrolledList context menus (used in debugger) now work on Mac Aqua. Patch by Mark Roseman.
- [bpo-24801](https://bugs.python.org/issue?@action=redirect&bpo=24801) [https://bugs.python.org/issue?@action=redirect&bpo=24801]: Make right-click for context menu work on Mac Aqua. Patch by Mark Roseman.
- [bpo-25173](https://bugs.python.org/issue?@action=redirect&bpo=25173) [https://bugs.python.org/issue?@action=redirect&bpo=25173]: Associate tkinter messageboxes with a specific widget. For Mac OSX, make them a ‘sheet’. Patch by Mark Roseman.
- [bpo-25198](https://bugs.python.org/issue?@action=redirect&bpo=25198) [https://bugs.python.org/issue?@action=redirect&bpo=25198]: Enhance the initial html viewer now used for Idle Help. Properly indent fixed-pitch text (patch by Mark Roseman). Give code snippet a very Sphinx-like light blueish-gray background. Re-use initial width and height set by users for shell and editor. When the Table of Contents (TOC) menu is used, put the section header at the top of the screen.
- [bpo-25225](https://bugs.python.org/issue?@action=redirect&bpo=25225) [https://bugs.python.org/issue?@action=redirect&bpo=25225]: Condense and rewrite Idle doc section on text colors.
- [bpo-21995](https://bugs.python.org/issue?@action=redirect&bpo=21995) [https://bugs.python.org/issue?@action=redirect&bpo=21995]: Explain some differences between IDLE and console Python.
- [bpo-22820](https://bugs.python.org/issue?@action=redirect&bpo=22820) [https://bugs.python.org/issue?@action=redirect&bpo=22820]: Explain need for *print* when running file from Idle editor.
- [bpo-25224](https://bugs.python.org/issue?@action=redirect&bpo=25224) [https://bugs.python.org/issue?@action=redirect&bpo=25224]: Doc: augment Idle feature list and no-subprocess section.
- [bpo-25219](https://bugs.python.org/issue?@action=redirect&bpo=25219) [https://bugs.python.org/issue?@action=redirect&bpo=25219]: Update doc for Idle command line

options. Some were missing and notes were not correct.

- [bpo-24861](https://bugs.python.org/issue?@action=redirect&bpo=24861) [https://bugs.python.org/issue?@action=redirect&bpo=24861]: Most of `idlelib` is private and subject to change. Use `idlelib.idle.*` to start Idle. See `idlelib._init_.doc_`.
- [bpo-25199](https://bugs.python.org/issue?@action=redirect&bpo=25199) [https://bugs.python.org/issue?@action=redirect&bpo=25199]: Idle: add synchronization comments for future maintainers.
- [bpo-16893](https://bugs.python.org/issue?@action=redirect&bpo=16893) [https://bugs.python.org/issue?@action=redirect&bpo=16893]: Replace `help.txt` with `help.html` for Idle doc display. The new `idlelib/help.html` is `rstripped Doc/build/html/library/idle.html`. It looks better than `help.txt` and will better document Idle as released. The `tkinter` `html` viewer that works for this file was written by Rose Roseman. The now unused `EditorWindow.HelpDialog` class and `helt.txt` file are deprecated.
- [bpo-24199](https://bugs.python.org/issue?@action=redirect&bpo=24199) [https://bugs.python.org/issue?@action=redirect&bpo=24199]: Deprecate unused `idlelib.idlever` with possible removal in 3.6.
- [bpo-24790](https://bugs.python.org/issue?@action=redirect&bpo=24790) [https://bugs.python.org/issue?@action=redirect&bpo=24790]: Remove extraneous code (which also create 2 & 3 conflicts).

## Documentation

- [bpo-26736](https://bugs.python.org/issue?@action=redirect&bpo=26736) [https://bugs.python.org/issue?@action=redirect&bpo=26736]: Used `HTTPS` for external links in the documentation if possible.
- [bpo-6953](https://bugs.python.org/issue?@action=redirect&bpo=6953) [https://bugs.python.org/issue?@action=redirect&bpo=6953]: Rework the `Readline` module documentation to group related functions together, and add more details such as what underlying `Readline` functions and variables are accessed.
- [bpo-23606](https://bugs.python.org/issue?@action=redirect&bpo=23606) [https://bugs.python.org/issue?@action=redirect&bpo=23606]: Adds note to `ctypes` documentation regarding `cdll.msvcrt`.
- [bpo-24952](https://bugs.python.org/issue?@action=redirect&bpo=24952) [https://bugs.python.org/issue?@action=redirect&bpo=24952]: Clarify the default size argument of `stack_size()` in the “`threading`” and “`_thread`” modules. Patch from Mattip.
- [bpo-26014](https://bugs.python.org/issue?@action=redirect&bpo=26014) [https://bugs.python.org/issue?@action=redirect&bpo=26014]

@action=redirect&bpo=26014]: Update 3.x packaging documentation: \* “See also” links to the new docs are now provided in the legacy pages \* links to setuptools documentation have been updated

## Tests

- [bpo-21916](https://bugs.python.org/issue?@action=redirect&bpo=21916) [https://bugs.python.org/issue?@action=redirect&bpo=21916]: Added tests for the turtle module. Patch by ingrid, Gregory Loyse and Jelle Zijlstra.
- [bpo-26295](https://bugs.python.org/issue?@action=redirect&bpo=26295) [https://bugs.python.org/issue?@action=redirect&bpo=26295]: When using “python3 -m test – testdir=TESTDIR”, regrtest doesn’t add “test.” prefix to test module names.
- [bpo-26523](https://bugs.python.org/issue?@action=redirect&bpo=26523) [https://bugs.python.org/issue?@action=redirect&bpo=26523]: The multiprocessing thread pool (multiprocessing.dummy.Pool) was untested.
- [bpo-26015](https://bugs.python.org/issue?@action=redirect&bpo=26015) [https://bugs.python.org/issue?@action=redirect&bpo=26015]: Added new tests for pickling iterators of mutable sequences.
- [bpo-26325](https://bugs.python.org/issue?@action=redirect&bpo=26325) [https://bugs.python.org/issue?@action=redirect&bpo=26325]: Added test.support.check\_no\_resource\_warning() to check that no ResourceWarning is emitted.
- [bpo-25940](https://bugs.python.org/issue?@action=redirect&bpo=25940) [https://bugs.python.org/issue?@action=redirect&bpo=25940]: Changed test\_ssl to use its internal local server more. This avoids relying on svn.python.org, which recently changed root certificate.
- [bpo-25616](https://bugs.python.org/issue?@action=redirect&bpo=25616) [https://bugs.python.org/issue?@action=redirect&bpo=25616]: Tests for OrderedDict are extracted from test\_collections into separate file test\_ordered\_dict.
- [bpo-25449](https://bugs.python.org/issue?@action=redirect&bpo=25449) [https://bugs.python.org/issue?@action=redirect&bpo=25449]: Added tests for OrderedDict subclasses.
- [bpo-25188](https://bugs.python.org/issue?@action=redirect&bpo=25188) [https://bugs.python.org/issue?@action=redirect&bpo=25188]: Add -P/-pgo to test.regrtest to suppress error output when running the test suite for the purposes of a PGO build. Initial patch by Alecsandru Patrascu.

- [bpo-22806](https://bugs.python.org/issue?@action=redirect&bpo=22806) [https://bugs.python.org/issue?@action=redirect&bpo=22806]: Add `python -m test --list-tests` command to list tests.
- [bpo-18174](https://bugs.python.org/issue?@action=redirect&bpo=18174) [https://bugs.python.org/issue?@action=redirect&bpo=18174]: `python -m test --huntrleaks` ... now also checks for leak of file descriptors. Patch written by Richard Oudkerk.
- [bpo-25260](https://bugs.python.org/issue?@action=redirect&bpo=25260) [https://bugs.python.org/issue?@action=redirect&bpo=25260]: Fix `python -m test --coverage` on Windows. Remove the list of ignored directories.
- `PCbuild\rt.bat` now accepts an unlimited number of arguments to pass along to `regtest.py`. Previously there was a limit of 9.
- [bpo-26583](https://bugs.python.org/issue?@action=redirect&bpo=26583) [https://bugs.python.org/issue?@action=redirect&bpo=26583]: Skip `test_timestamp_overflow` in `test_import` if bytecode files cannot be written.

## Build

- [bpo-21277](https://bugs.python.org/issue?@action=redirect&bpo=21277) [https://bugs.python.org/issue?@action=redirect&bpo=21277]: Don't try to link `_ctypes` with a `ffi_convenience` library.
- [bpo-26884](https://bugs.python.org/issue?@action=redirect&bpo=26884) [https://bugs.python.org/issue?@action=redirect&bpo=26884]: Fix linking extension modules for cross builds. Patch by Xavier de Gaye.
- [bpo-26932](https://bugs.python.org/issue?@action=redirect&bpo=26932) [https://bugs.python.org/issue?@action=redirect&bpo=26932]: Fixed support of `RTLD_*` constants defined as enum values, not via macros (in particular on Android). Patch by Chi Hsuan Yen.
- [bpo-22359](https://bugs.python.org/issue?@action=redirect&bpo=22359) [https://bugs.python.org/issue?@action=redirect&bpo=22359]: Disable the rules for running `_freeze_importlib` and `pgen` when cross-compiling. The output of these programs is normally saved with the source code anyway, and is still regenerated when doing a native build. Patch by Xavier de Gaye.
- [bpo-21668](https://bugs.python.org/issue?@action=redirect&bpo=21668) [https://bugs.python.org/issue?@action=redirect&bpo=21668]: Link `audioop`, `_datetime`, `_ctypes_test` modules to `libm`, except on Mac OS X. Patch written by Chi Hsuan Yen.

- [bpo-25702](https://bugs.python.org/issue?@action=redirect&bpo=25702) [https://bugs.python.org/issue?@action=redirect&bpo=25702]: A `--with-lto` configure option has been added that will enable link time optimizations at build time during a `make profile-opt`. Some compilers and toolchains are known to not produce stable code when using LTO, be sure to test things thoroughly before relying on it. It can provide a few % speed up over `profile-opt` alone.
- [bpo-26624](https://bugs.python.org/issue?@action=redirect&bpo=26624) [https://bugs.python.org/issue?@action=redirect&bpo=26624]: Adds validation of `ucrtbase[d].dll` version with warning for old versions.
- [bpo-17603](https://bugs.python.org/issue?@action=redirect&bpo=17603) [https://bugs.python.org/issue?@action=redirect&bpo=17603]: Avoid error about nonexistent `fileblocks.o` file by using a lower-level check for `st_blocks` in struct `stat`.
- [bpo-26079](https://bugs.python.org/issue?@action=redirect&bpo=26079) [https://bugs.python.org/issue?@action=redirect&bpo=26079]: Fixing the build output folder for `tix-8.4.3.6`. Patch by Bjoern Thiel.
- [bpo-26465](https://bugs.python.org/issue?@action=redirect&bpo=26465) [https://bugs.python.org/issue?@action=redirect&bpo=26465]: Update Windows builds to use OpenSSL 1.0.2g.
- [bpo-25348](https://bugs.python.org/issue?@action=redirect&bpo=25348) [https://bugs.python.org/issue?@action=redirect&bpo=25348]: Added `--pgo` and `--pgo-job` arguments to `PCbuild\build.bat` for building with Profile-Guided Optimization. The old `PCbuild\build_pgo.bat` script is removed.
- [bpo-25827](https://bugs.python.org/issue?@action=redirect&bpo=25827) [https://bugs.python.org/issue?@action=redirect&bpo=25827]: Add support for building with ICC to configure, including a new `--with-icc` flag.
- [bpo-25696](https://bugs.python.org/issue?@action=redirect&bpo=25696) [https://bugs.python.org/issue?@action=redirect&bpo=25696]: Fix installation of Python on UNIX with `make -j9`.
- [bpo-24986](https://bugs.python.org/issue?@action=redirect&bpo=24986) [https://bugs.python.org/issue?@action=redirect&bpo=24986]: It is now possible to build Python on Windows without errors when external libraries are not available.
- [bpo-24421](https://bugs.python.org/issue?@action=redirect&bpo=24421) [https://bugs.python.org/issue?@action=redirect&bpo=24421]: Compile `Modules/_math.c` once, before building extensions. Previously it could fail to compile properly if the `math` and `cmath` builds were concurrent.
- [bpo-26465](https://bugs.python.org/issue?@action=redirect&bpo=26465) [https://bugs.python.org/issue?@action=redirect&bpo=26465]

@action=redirect&bpo=26465]: Update OS X 10.5 + 32-bit-only installer to build and link with OpenSSL 1.0.2g.

- [bpo-26268](https://bugs.python.org/issue?@action=redirect&bpo=26268) [https://bugs.python.org/issue?@action=redirect&bpo=26268]: Update Windows builds to use OpenSSL 1.0.2f.
- [bpo-25136](https://bugs.python.org/issue?@action=redirect&bpo=25136) [https://bugs.python.org/issue?@action=redirect&bpo=25136]: Support Apple Xcode 7's new textual SDK stub libraries.
- [bpo-24324](https://bugs.python.org/issue?@action=redirect&bpo=24324) [https://bugs.python.org/issue?@action=redirect&bpo=24324]: Do not enable unreachable code warnings when using gcc as the option does not work correctly in older versions of gcc and has been silently removed as of gcc-4.5.

## Windows

- [bpo-27053](https://bugs.python.org/issue?@action=redirect&bpo=27053) [https://bugs.python.org/issue?@action=redirect&bpo=27053]: Updates make\_zip.py to correctly generate library ZIP file.
- [bpo-26268](https://bugs.python.org/issue?@action=redirect&bpo=26268) [https://bugs.python.org/issue?@action=redirect&bpo=26268]: Update the prepare\_ssl.py script to handle OpenSSL releases that don't include the contents of the include directory (that is, 1.0.2e and later).
- [bpo-26071](https://bugs.python.org/issue?@action=redirect&bpo=26071) [https://bugs.python.org/issue?@action=redirect&bpo=26071]: bdist\_wininst created binaries fail to start and find 32bit Python
- [bpo-26073](https://bugs.python.org/issue?@action=redirect&bpo=26073) [https://bugs.python.org/issue?@action=redirect&bpo=26073]: Update the list of magic numbers in launcher
- [bpo-26065](https://bugs.python.org/issue?@action=redirect&bpo=26065) [https://bugs.python.org/issue?@action=redirect&bpo=26065]: Excludes venv from library when generating embeddable distro.
- [bpo-25022](https://bugs.python.org/issue?@action=redirect&bpo=25022) [https://bugs.python.org/issue?@action=redirect&bpo=25022]: Removed very outdated PC/example\_nt/ directory.

## Tools/Demos

- [bpo-26799](https://bugs.python.org/issue?@action=redirect&bpo=26799) [https://bugs.python.org/issue?@action=redirect&bpo=26799]: Fix python-gdb.py: don't get C

types once when the Python code is loaded, but get C types on demand. The C types can change if `python-gdb.py` is loaded before the Python executable. Patch written by Thomas Ilsche.

- [bpo-26271](https://bugs.python.org/issue?@action=redirect&bpo=26271) [https://bugs.python.org/issue?@action=redirect&bpo=26271]: Fix the Freeze tool to properly use flags passed through `configure`. Patch by Daniel Shaulov.
- [bpo-26489](https://bugs.python.org/issue?@action=redirect&bpo=26489) [https://bugs.python.org/issue?@action=redirect&bpo=26489]: Add dictionary unpacking support to `Tools/parser/unparse.py`. Patch by Guo Ci Teo.
- [bpo-26316](https://bugs.python.org/issue?@action=redirect&bpo=26316) [https://bugs.python.org/issue?@action=redirect&bpo=26316]: Fix variable name typo in `Argument Clinic`.
- [bpo-25440](https://bugs.python.org/issue?@action=redirect&bpo=25440) [https://bugs.python.org/issue?@action=redirect&bpo=25440]: Fix output of `python-config --extension-suffix`.
- [bpo-25154](https://bugs.python.org/issue?@action=redirect&bpo=25154) [https://bugs.python.org/issue?@action=redirect&bpo=25154]: The `pyvenv` script has been deprecated in favour of **`python3 -m venv`**.

## C API

- [bpo-26312](https://bugs.python.org/issue?@action=redirect&bpo=26312) [https://bugs.python.org/issue?@action=redirect&bpo=26312]: `SystemError` is now raised in all programming bugs with using `PyArg_ParseTupleAndKeywords()`. `RuntimeError` did raised before in some programming bugs.
- [bpo-26198](https://bugs.python.org/issue?@action=redirect&bpo=26198) [https://bugs.python.org/issue?@action=redirect&bpo=26198]: `ValueError` is now raised instead of `TypeError` on buffer overflow in parsing “`es#`” and “`et#`” format units. `SystemError` is now raised instead of `TypeError` on grammatical error in parsing format string.

## Python 3.5.5 final

*Release date: 2018-02-04*

There were no new changes in version 3.5.5.

# Python 3.5.5 release candidate 1

*Release date: 2018-01-23*

## Security

- [bpo-32551](https://bugs.python.org/issue?@action=redirect&bpo=32551) [https://bugs.python.org/issue?@action=redirect&bpo=32551]: The `sys.path[0]` initialization change for [bpo-29139](https://bugs.python.org/issue?@action=redirect&bpo=29139) [https://bugs.python.org/issue?@action=redirect&bpo=29139] caused a regression by revealing an inconsistency in how `sys.path` is initialized when executing `__main__` from a zipfile, directory, or other import location. This is considered a potential security issue, as it may lead to privileged processes unexpectedly loading code from user controlled directories in situations where that was not previously the case. The interpreter now consistently avoids ever adding the import location's parent directory to `sys.path`, and ensures no other `sys.path` entries are inadvertently modified when inserting the import location named on the command line. (Originally reported as [bpo-29723](https://bugs.python.org/issue?@action=redirect&bpo=29723) [https://bugs.python.org/issue?@action=redirect&bpo=29723] against Python 3.6rc1, but it was missed at the time that the then upcoming Python 3.5.4 release would also be affected)
- [bpo-30657](https://bugs.python.org/issue?@action=redirect&bpo=30657) [https://bugs.python.org/issue?@action=redirect&bpo=30657]: Fixed possible integer overflow in `PyBytes_DecodeEscape`, CVE-2017-1000158. Original patch by Jay Bosamiya; rebased to Python 3 by Miro Hrončok.
- [bpo-30947](https://bugs.python.org/issue?@action=redirect&bpo=30947) [https://bugs.python.org/issue?@action=redirect&bpo=30947]: Upgrade libexpat embedded copy from version 2.2.1 to 2.2.3 to get security fixes.

## Core and Builtins

- [bpo-31095](https://bugs.python.org/issue?@action=redirect&bpo=31095) [https://bugs.python.org/issue?@action=redirect&bpo=31095]: Fix potential crash during GC caused by `tp_dealloc` which doesn't call `PyObject_GC_UnTrack()`.

## Library

- [bpo-32072](https://bugs.python.org/issue?@action=redirect&bpo=32072) [https://bugs.python.org/issue?@action=redirect&bpo=32072]: Fixed issues with binary plists: Fixed saving bytearray. Identical objects will be saved only once. Equal references will be load as identical objects. Added support for saving and loading recursive data structures.
- [bpo-31170](https://bugs.python.org/issue?@action=redirect&bpo=31170) [https://bugs.python.org/issue?@action=redirect&bpo=31170]: `expat`: Update `libexpat` from 2.2.3 to 2.2.4. Fix copying of partial characters for UTF-8 input (`libexpat` bug 115): <https://github.com/libexpat/libexpat/issues/115>

## Python 3.5.4 final

*Release date: 2017-08-07*

## Library

- [bpo-30119](https://bugs.python.org/issue?@action=redirect&bpo=30119) [https://bugs.python.org/issue?@action=redirect&bpo=30119]: `ftplib.FTP.putline()` now throws `ValueError` on commands that contains CR or LF. Patch by Dong-hee Na.

## Python 3.5.4 release candidate 1

*Release date: 2017-07-23*

## Security

- [bpo-30730](https://bugs.python.org/issue?@action=redirect&bpo=30730) [https://bugs.python.org/issue?@action=redirect&bpo=30730]: Prevent environment variables injection in subprocess on Windows. Prevent passing other environment variables and command arguments.
- [bpo-30694](https://bugs.python.org/issue?@action=redirect&bpo=30694) [https://bugs.python.org/issue?@action=redirect&bpo=30694]: Upgrade `expat` copy from 2.2.0 to 2.2.1 to get fixes of multiple security vulnerabilities including: CVE-2017-9233 (External entity infinite loop DoS),

CVE-2016-9063 (Integer overflow, re-fix), CVE-2016-0718 (Fix regression bugs from 2.2.0's fix to CVE-2016-0718) and CVE-2012-0876 (Counter hash flooding with SipHash). Note: the CVE-2016-5300 (Use os-specific entropy sources like `getrandom`) doesn't impact Python, since Python already gets entropy from the OS to set the expat secret using `XML_SetHashSalt()`.

- [bpo-30500](https://bugs.python.org/issue?@action=redirect&bpo=30500) [https://bugs.python.org/issue?@action=redirect&bpo=30500]: Fix `urllib.parse.splithost()` to correctly parse fragments. For example, `splithost('//127.0.0.1#@evil.com/')` now correctly returns the `127.0.0.1` host, instead of treating `@evil.com` as the host in an authentication (`login@host`).
- [bpo-29591](https://bugs.python.org/issue?@action=redirect&bpo=29591) [https://bugs.python.org/issue?@action=redirect&bpo=29591]: Update expat copy from 2.1.1 to 2.2.0 to get fixes of CVE-2016-0718 and CVE-2016-4472. See <https://sourceforge.net/p/expat/bugs/537/> for more information.

## Core and Builtins

- [bpo-30876](https://bugs.python.org/issue?@action=redirect&bpo=30876) [https://bugs.python.org/issue?@action=redirect&bpo=30876]: Relative import from unloaded package now reimports the package instead of failing with `SystemError`. Relative import from non-package now fails with `ImportError` rather than `SystemError`.
- [bpo-30765](https://bugs.python.org/issue?@action=redirect&bpo=30765) [https://bugs.python.org/issue?@action=redirect&bpo=30765]: Avoid blocking in `pthread_mutex_lock()` when `PyThread_acquire_lock()` is asked not to block.
- [bpo-27945](https://bugs.python.org/issue?@action=redirect&bpo=27945) [https://bugs.python.org/issue?@action=redirect&bpo=27945]: Fixed various segfaults with dict when input collections are mutated during searching, inserting or comparing. Based on patches by Duane Griffin and Tim Mitchell.
- [bpo-25794](https://bugs.python.org/issue?@action=redirect&bpo=25794) [https://bugs.python.org/issue?@action=redirect&bpo=25794]: Fixed `type._setattr_()` and `type._delattr_()` for non-interned attribute names. Based on patch by Eryk Sun.
- [bpo-29935](https://bugs.python.org/issue?@action=redirect&bpo=29935) [https://bugs.python.org/issue?@action=redirect&bpo=29935]

@action=redirect&bpo=29935]: Fixed error messages in the `index()` method of tuple, list and deque when pass indices of wrong type.

- [bpo-28876](https://bugs.python.org/issue?@action=redirect&bpo=28876) [https://bugs.python.org/issue?@action=redirect&bpo=28876]: `bool(range)` works even if `len(range)` raises **OverflowError**.
- [bpo-29600](https://bugs.python.org/issue?@action=redirect&bpo=29600) [https://bugs.python.org/issue?@action=redirect&bpo=29600]: Fix wrapping coroutine return values in `StopIteration`.
- [bpo-29537](https://bugs.python.org/issue?@action=redirect&bpo=29537) [https://bugs.python.org/issue?@action=redirect&bpo=29537]: Restore runtime compatibility with bytecode files generated by CPython 3.5.0 to 3.5.2, and adjust the eval loop to avoid the problems that could be caused by the malformed variant of the `BUILD_MAP_UNPACK_WITH_CALL` opcode that they may contain. Patch by Petr Viktorin, Serhiy Storchaka, and Nick Coghlan.
- [bpo-28598](https://bugs.python.org/issue?@action=redirect&bpo=28598) [https://bugs.python.org/issue?@action=redirect&bpo=28598]: Support `__rmod__` for subclasses of `str` being called before `str.__mod__`. Patch by Martijn Pieters.
- [bpo-29602](https://bugs.python.org/issue?@action=redirect&bpo=29602) [https://bugs.python.org/issue?@action=redirect&bpo=29602]: Fix incorrect handling of signed zeros in complex constructor for complex subclasses and for inputs having a `__complex__` method. Patch by Serhiy Storchaka.
- [bpo-29347](https://bugs.python.org/issue?@action=redirect&bpo=29347) [https://bugs.python.org/issue?@action=redirect&bpo=29347]: Fixed possibly dereferencing undefined pointers when creating weakref objects.
- [bpo-29438](https://bugs.python.org/issue?@action=redirect&bpo=29438) [https://bugs.python.org/issue?@action=redirect&bpo=29438]: Fixed use-after-free problem in key sharing dict.
- [bpo-29319](https://bugs.python.org/issue?@action=redirect&bpo=29319) [https://bugs.python.org/issue?@action=redirect&bpo=29319]: Prevent `RunMainFromImporter` overwriting `sys.path[0]`.
- [bpo-29337](https://bugs.python.org/issue?@action=redirect&bpo=29337) [https://bugs.python.org/issue?@action=redirect&bpo=29337]: Fixed possible `BytesWarning` when compare the code objects. Warnings could be emitted at compile time.
- [bpo-29478](https://bugs.python.org/issue?@action=redirect&bpo=29478) [https://bugs.python.org/issue?@action=redirect&bpo=29478]: If `max_line_length = None` is

specified while using the Compat32 policy, it is no longer ignored. Patch by Mircea Cosbuc.

## Library

- [bpo-29403](https://bugs.python.org/issue?@action=redirect&bpo=29403) [https://bugs.python.org/issue?@action=redirect&bpo=29403]: Fix `unittest.mock`'s `autospec` to not fail on method-bound builtin functions. Patch by Aaron Gallagher.
- [bpo-30961](https://bugs.python.org/issue?@action=redirect&bpo=30961) [https://bugs.python.org/issue?@action=redirect&bpo=30961]: Fix decrementing a borrowed reference in `tracemalloc`.
- [bpo-30886](https://bugs.python.org/issue?@action=redirect&bpo=30886) [https://bugs.python.org/issue?@action=redirect&bpo=30886]: Fix `multiprocessing.Queue.join_thread()`: it now waits until the thread completes, even if the thread was started by the same process which created the queue.
- [bpo-29854](https://bugs.python.org/issue?@action=redirect&bpo=29854) [https://bugs.python.org/issue?@action=redirect&bpo=29854]: Fix `segfault` in `readline` when using `readline`'s `history-size` option. Patch by Nir Soffer.
- [bpo-30807](https://bugs.python.org/issue?@action=redirect&bpo=30807) [https://bugs.python.org/issue?@action=redirect&bpo=30807]: `signal.setitimer()` may disable the timer when passed a tiny value. Tiny values (such as `1e-6`) are valid non-zero values for `setitimer()`, which is specified as taking `microsecond-resolution` intervals. However, on some platform, our conversion routine could convert `1e-6` into a zero interval, therefore disabling the timer instead of (re-)scheduling it.
- [bpo-30441](https://bugs.python.org/issue?@action=redirect&bpo=30441) [https://bugs.python.org/issue?@action=redirect&bpo=30441]: Fix bug when modifying `os.environ` while iterating over it
- [bpo-30532](https://bugs.python.org/issue?@action=redirect&bpo=30532) [https://bugs.python.org/issue?@action=redirect&bpo=30532]: Fix email header value parser dropping folding white space in certain cases.
- [bpo-29169](https://bugs.python.org/issue?@action=redirect&bpo=29169) [https://bugs.python.org/issue?@action=redirect&bpo=29169]: Update `zlib` to 1.2.11.
- [bpo-30879](https://bugs.python.org/issue?@action=redirect&bpo=30879) [https://bugs.python.org/issue?@action=redirect&bpo=30879]: `os.listdir()` and `os.scandir()` now emit bytes names when called with bytes-like argument.
- [bpo-30746](https://bugs.python.org/issue?@action=redirect&bpo=30746) [https://bugs.python.org/issue?@action=redirect&bpo=30746]

@action=redirect&bpo=30746]: Prohibited the ‘=’ character in environment variable names in `os.putenv()` and `os.spawn*()`.

- [bpo-29755](https://bugs.python.org/issue?@action=redirect&bpo=29755) [https://bugs.python.org/issue?@action=redirect&bpo=29755]: Fixed the `gettext()` family of functions in the `gettext` module. They now always return bytes.
- [bpo-30645](https://bugs.python.org/issue?@action=redirect&bpo=30645) [https://bugs.python.org/issue?@action=redirect&bpo=30645]: Fix path calculation in `imp.load_package()`, fixing it for cases when a package is only shipped with bytecodes. Patch by Alexandru Ardelean.
- [bpo-23890](https://bugs.python.org/issue?@action=redirect&bpo=23890) [https://bugs.python.org/issue?@action=redirect&bpo=23890]: `unittest.TestCase.assertRaises()` now manually breaks a reference cycle to not keep objects alive longer than expected.
- [bpo-30149](https://bugs.python.org/issue?@action=redirect&bpo=30149) [https://bugs.python.org/issue?@action=redirect&bpo=30149]: `inspect.signature()` now supports callables with variable-argument parameters wrapped with `partialmethod`. Patch by Dong-hee Na.
- [bpo-29931](https://bugs.python.org/issue?@action=redirect&bpo=29931) [https://bugs.python.org/issue?@action=redirect&bpo=29931]: Fixed comparison check for `ipaddress.ip_interface` objects. Patch by Sanjay Sundaresan.
- [bpo-24484](https://bugs.python.org/issue?@action=redirect&bpo=24484) [https://bugs.python.org/issue?@action=redirect&bpo=24484]: Avoid race condition in multiprocessing cleanup.
- [bpo-28994](https://bugs.python.org/issue?@action=redirect&bpo=28994) [https://bugs.python.org/issue?@action=redirect&bpo=28994]: The traceback no longer displayed for `SystemExit` raised in a callback registered by `atexit`.
- [bpo-30508](https://bugs.python.org/issue?@action=redirect&bpo=30508) [https://bugs.python.org/issue?@action=redirect&bpo=30508]: Don't log exceptions if `Task/Future "cancel()"` method was called.
- [bpo-28556](https://bugs.python.org/issue?@action=redirect&bpo=28556) [https://bugs.python.org/issue?@action=redirect&bpo=28556]: Updates to typing module: Add generic `AsyncContextManager`, add support for `ContextManager` on all versions. Original PRs by Jelle Zijlstra and Ivan Levkivskyi
- [bpo-29870](https://bugs.python.org/issue?@action=redirect&bpo=29870) [https://bugs.python.org/issue?@action=redirect&bpo=29870]: Fix `ssl` sockets leaks when connection is aborted in `asyncio/ssl` implementation. Patch by Michaël Sghaïer.

- [bpo-29743](https://bugs.python.org/issue?@action=redirect&bpo=29743) [https://bugs.python.org/issue?@action=redirect&bpo=29743]: Closing transport during handshake process leaks open socket. Patch by Nikolay Kim
- [bpo-27585](https://bugs.python.org/issue?@action=redirect&bpo=27585) [https://bugs.python.org/issue?@action=redirect&bpo=27585]: Fix waiter cancellation in `asyncio.Lock`. Patch by Mathieu Sornay.
- [bpo-30418](https://bugs.python.org/issue?@action=redirect&bpo=30418) [https://bugs.python.org/issue?@action=redirect&bpo=30418]: On Windows, `subprocess.Popen.communicate()` now also ignore `EINVAL` on `stdin.write()` if the child process is still running but closed the pipe.
- [bpo-30378](https://bugs.python.org/issue?@action=redirect&bpo=30378) [https://bugs.python.org/issue?@action=redirect&bpo=30378]: Fix the problem that `logging.handlers.SysLogHandler` cannot handle IPv6 addresses.
- [bpo-29960](https://bugs.python.org/issue?@action=redirect&bpo=29960) [https://bugs.python.org/issue?@action=redirect&bpo=29960]: Preserve generator state when `_random.Random.setstate()` raises an exception. Patch by Bryan Olson.
- [bpo-30414](https://bugs.python.org/issue?@action=redirect&bpo=30414) [https://bugs.python.org/issue?@action=redirect&bpo=30414]: `multiprocessing.Queue._feed` background running thread do not break from main loop on exception.
- [bpo-30003](https://bugs.python.org/issue?@action=redirect&bpo=30003) [https://bugs.python.org/issue?@action=redirect&bpo=30003]: Fix handling escape characters in HZ codec. Based on patch by Ma Lin.
- [bpo-30301](https://bugs.python.org/issue?@action=redirect&bpo=30301) [https://bugs.python.org/issue?@action=redirect&bpo=30301]: Fix `AttributeError` when using `SimpleQueue.empty()` under *spawn* and *forkserver* start methods.
- [bpo-30329](https://bugs.python.org/issue?@action=redirect&bpo=30329) [https://bugs.python.org/issue?@action=redirect&bpo=30329]: `imaplib` and `poplib` now catch the Windows socket `WSAEINVAL` error (code 10022) on `shutdown(SHUT_RDWR)`: An invalid operation was attempted. This error occurs sometimes on SSL connections.
- [bpo-30375](https://bugs.python.org/issue?@action=redirect&bpo=30375) [https://bugs.python.org/issue?@action=redirect&bpo=30375]: Warnings emitted when compile a regular expression now always point to the line in the user code. Previously they could point into inners of the `re` module if emitted from inside of groups or conditionals.

- [bpo-30048](https://bugs.python.org/issue?@action=redirect&bpo=30048) [https://bugs.python.org/issue?@action=redirect&bpo=30048]: Fixed `Task.cancel()` can be ignored when the task is running coroutine and the coroutine returned without any more `await`.
- [bpo-29990](https://bugs.python.org/issue?@action=redirect&bpo=29990) [https://bugs.python.org/issue?@action=redirect&bpo=29990]: Fix range checking in GB18030 decoder. Original patch by Ma Lin.
- [bpo-26293](https://bugs.python.org/issue?@action=redirect&bpo=26293) [https://bugs.python.org/issue?@action=redirect&bpo=26293]: Change resulted because of zipfile breakage. (See also: [bpo-29094](https://bugs.python.org/issue?@action=redirect&bpo=29094) [https://bugs.python.org/issue?@action=redirect&bpo=29094])
- [bpo-30243](https://bugs.python.org/issue?@action=redirect&bpo=30243) [https://bugs.python.org/issue?@action=redirect&bpo=30243]: Removed the `_init_` methods of `_json`'s scanner and encoder. Misusing them could cause memory leaks or crashes. Now scanner and encoder objects are completely initialized in the `_new_` methods.
- [bpo-30185](https://bugs.python.org/issue?@action=redirect&bpo=30185) [https://bugs.python.org/issue?@action=redirect&bpo=30185]: Avoid KeyboardInterrupt tracebacks in forserver helper process when Ctrl-C is received.
- [bpo-28556](https://bugs.python.org/issue?@action=redirect&bpo=28556) [https://bugs.python.org/issue?@action=redirect&bpo=28556]: Various updates to typing module: add typing.NoReturn type, use WrapperDescriptorType, minor bug-fixes. Original PRs by Jim Fasarakis-Hilliard and Ivan Levkivskyi.
- [bpo-30205](https://bugs.python.org/issue?@action=redirect&bpo=30205) [https://bugs.python.org/issue?@action=redirect&bpo=30205]: Fix `getsockname()` for unbound AF\_UNIX sockets on Linux.
- [bpo-30070](https://bugs.python.org/issue?@action=redirect&bpo=30070) [https://bugs.python.org/issue?@action=redirect&bpo=30070]: Fixed leaks and crashes in errors handling in the parser module.
- [bpo-30061](https://bugs.python.org/issue?@action=redirect&bpo=30061) [https://bugs.python.org/issue?@action=redirect&bpo=30061]: Fixed crashes in IOBase methods `_next_()` and `readlines()` when `readline()` or `_next_()` respectively return non-sizeable object. Fixed possible other errors caused by not checking results of `PyObject_Size()`, `PySequence_Size()`, or `PyMapping_Size()`.
- [bpo-30068](https://bugs.python.org/issue?@action=redirect&bpo=30068) [https://bugs.python.org/issue?@action=redirect&bpo=30068]: `_io.IOBase.readlines` will check if it's closed first when hint is present.

- [bpo-29694](https://bugs.python.org/issue?@action=redirect&bpo=29694) [https://bugs.python.org/issue?@action=redirect&bpo=29694]: Fixed race condition in `pathlib.mkdir` with `flags parents=True`. Patch by Armin Rigo.
- [bpo-29692](https://bugs.python.org/issue?@action=redirect&bpo=29692) [https://bugs.python.org/issue?@action=redirect&bpo=29692]: Fixed arbitrary unchaining of `RuntimeError` exceptions in `contextlib.contextmanager`. Patch by Siddharth Velankar.
- [bpo-29998](https://bugs.python.org/issue?@action=redirect&bpo=29998) [https://bugs.python.org/issue?@action=redirect&bpo=29998]: Pickling and copying `ImportError` now preserves name and path attributes.
- [bpo-29942](https://bugs.python.org/issue?@action=redirect&bpo=29942) [https://bugs.python.org/issue?@action=redirect&bpo=29942]: Fix a crash in `itertools.chain.from_iterable` when encountering long runs of empty iterables.
- [bpo-27863](https://bugs.python.org/issue?@action=redirect&bpo=27863) [https://bugs.python.org/issue?@action=redirect&bpo=27863]: Fixed multiple crashes in `ElementTree` caused by race conditions and wrong types.
- [bpo-28699](https://bugs.python.org/issue?@action=redirect&bpo=28699) [https://bugs.python.org/issue?@action=redirect&bpo=28699]: Fixed a bug in pools in `multiprocessing.pool` that raising an exception at the very first of an iterable may swallow the exception or make the program hang. Patch by Davin Potts and Xiang Zhang.
- [bpo-25803](https://bugs.python.org/issue?@action=redirect&bpo=25803) [https://bugs.python.org/issue?@action=redirect&bpo=25803]: Avoid incorrect errors raised by `Path.mkdir(exist_ok=True)` when the OS gives priority to errors such as `EACCES` over `EEXIST`.
- [bpo-29861](https://bugs.python.org/issue?@action=redirect&bpo=29861) [https://bugs.python.org/issue?@action=redirect&bpo=29861]: Release references to tasks, their arguments and their results as soon as they are finished in `multiprocessing.Pool`.
- [bpo-29884](https://bugs.python.org/issue?@action=redirect&bpo=29884) [https://bugs.python.org/issue?@action=redirect&bpo=29884]: `faulthandler`: Restore the old `sigaltstack` during teardown. Patch by Christophe Zeitouny.
- [bpo-25455](https://bugs.python.org/issue?@action=redirect&bpo=25455) [https://bugs.python.org/issue?@action=redirect&bpo=25455]: Fixed crashes in `repr` of recursive buffered file-like objects.
- [bpo-29800](https://bugs.python.org/issue?@action=redirect&bpo=29800) [https://bugs.python.org/issue?@action=redirect&bpo=29800]: Fix crashes in `partial._repr_` if the keys of `partial.keywords` are not strings. Patch by Michael Seifert.

- [bpo-29742](https://bugs.python.org/issue?@action=redirect&bpo=29742) [https://bugs.python.org/issue?@action=redirect&bpo=29742]: `get_extra_info()` raises exception if get called on closed ssl transport. Patch by Nikolay Kim.
- [bpo-8256](https://bugs.python.org/issue?@action=redirect&bpo=8256) [https://bugs.python.org/issue?@action=redirect&bpo=8256]: Fixed possible failing or crashing `input()` if attributes “encoding” or “errors” of `sys.stdin` or `sys.stdout` are not set or are not strings.
- [bpo-28298](https://bugs.python.org/issue?@action=redirect&bpo=28298) [https://bugs.python.org/issue?@action=redirect&bpo=28298]: Fix a bug that prevented array ‘Q’, ‘L’ and ‘I’ from accepting big intables (objects that have `__int__`) as elements. Patch by Oren Milman.
- [bpo-29615](https://bugs.python.org/issue?@action=redirect&bpo=29615) [https://bugs.python.org/issue?@action=redirect&bpo=29615]: `SimpleXMLRPCDispatcher` no longer chains `KeyError` (or any other exception) to exception(s) raised in the dispatched methods. Patch by Petr Motejlek.
- [bpo-29704](https://bugs.python.org/issue?@action=redirect&bpo=29704) [https://bugs.python.org/issue?@action=redirect&bpo=29704]: `asyncio.subprocess.SubprocessStreamProtocol` no longer closes before all pipes are closed.
- [bpo-29703](https://bugs.python.org/issue?@action=redirect&bpo=29703) [https://bugs.python.org/issue?@action=redirect&bpo=29703]: Fix `asyncio` to support instantiation of new event loops in child processes.
- [bpo-29376](https://bugs.python.org/issue?@action=redirect&bpo=29376) [https://bugs.python.org/issue?@action=redirect&bpo=29376]: Fix assertion error in `threading._DummyThread.is_alive()`.
- [bpo-29110](https://bugs.python.org/issue?@action=redirect&bpo=29110) [https://bugs.python.org/issue?@action=redirect&bpo=29110]: Fix file object leak in `aifc.open()` when file is given as a filesystem path and is not in valid AIFF format. Patch by Anthony Zhang.
- [bpo-28961](https://bugs.python.org/issue?@action=redirect&bpo=28961) [https://bugs.python.org/issue?@action=redirect&bpo=28961]: Fix `unittest.mock._Call` helper: don’t ignore the name parameter anymore. Patch written by Jiajun Huang.
- [bpo-29532](https://bugs.python.org/issue?@action=redirect&bpo=29532) [https://bugs.python.org/issue?@action=redirect&bpo=29532]: Altering a kwarg dictionary passed to `functools.partial()` no longer affects a partial object after creation.
- [bpo-28556](https://bugs.python.org/issue?@action=redirect&bpo=28556) [https://bugs.python.org/issue?@action=redirect&bpo=28556]: Various updates to typing module:

typing.Counter, typing.ChainMap, improved ABC caching, etc. Original PRs by Jelle Zijlstra, Ivan Levkivskyi, Manuel Krebber, and Łukasz Langa.

- [bpo-29100](https://bugs.python.org/issue?@action=redirect&bpo=29100) [https://bugs.python.org/issue?@action=redirect&bpo=29100]: Fix datetime.fromtimestamp() regression introduced in Python 3.6.0: check minimum and maximum years.
- [bpo-29519](https://bugs.python.org/issue?@action=redirect&bpo=29519) [https://bugs.python.org/issue?@action=redirect&bpo=29519]: Fix weakref spewing exceptions during interpreter shutdown when used with a rare combination of multiprocessing and custom codecs.
- [bpo-29416](https://bugs.python.org/issue?@action=redirect&bpo=29416) [https://bugs.python.org/issue?@action=redirect&bpo=29416]: Prevent infinite loop in pathlib.Path.mkdir
- [bpo-29444](https://bugs.python.org/issue?@action=redirect&bpo=29444) [https://bugs.python.org/issue?@action=redirect&bpo=29444]: Fixed out-of-bounds buffer access in the group() method of the match object. Based on patch by WGH.
- [bpo-29335](https://bugs.python.org/issue?@action=redirect&bpo=29335) [https://bugs.python.org/issue?@action=redirect&bpo=29335]: Fix subprocess.Popen.wait() when the child process has exited to a stopped instead of terminated state (ex: when under ptrace).
- [bpo-29290](https://bugs.python.org/issue?@action=redirect&bpo=29290) [https://bugs.python.org/issue?@action=redirect&bpo=29290]: Fix a regression in argparse that help messages would wrap at non-breaking spaces.
- [bpo-28735](https://bugs.python.org/issue?@action=redirect&bpo=28735) [https://bugs.python.org/issue?@action=redirect&bpo=28735]: Fixed the comparison of mock.MagicMock with mock.ANY.
- [bpo-29011](https://bugs.python.org/issue?@action=redirect&bpo=29011) [https://bugs.python.org/issue?@action=redirect&bpo=29011]: Fix an important omission by adding Deque to the typing module.
- [bpo-29219](https://bugs.python.org/issue?@action=redirect&bpo=29219) [https://bugs.python.org/issue?@action=redirect&bpo=29219]: Fixed infinite recursion in the repr of uninitialized ctypes.CDLL instances.
- [bpo-28969](https://bugs.python.org/issue?@action=redirect&bpo=28969) [https://bugs.python.org/issue?@action=redirect&bpo=28969]: Fixed race condition in C implementation of functools.lru\_cache. KeyError could be raised when cached function with full cache was simultaneously called from different threads with the same uncached arguments.

- [bpo-29142](https://bugs.python.org/issue?@action=redirect&bpo=29142) [https://bugs.python.org/issue?@action=redirect&bpo=29142]: In urllib.request, suffixes in no\_proxy environment variable with leading dots could match related hostnames again (e.g. .b.c matches a.b.c). Patch by Milan Oberkirch.

## Documentation

- [bpo-30176](https://bugs.python.org/issue?@action=redirect&bpo=30176) [https://bugs.python.org/issue?@action=redirect&bpo=30176]: Add missing attribute related constants in curses documentation.
- [bpo-26985](https://bugs.python.org/issue?@action=redirect&bpo=26985) [https://bugs.python.org/issue?@action=redirect&bpo=26985]: Add missing info of code object in inspect documentation.
- [bpo-28929](https://bugs.python.org/issue?@action=redirect&bpo=28929) [https://bugs.python.org/issue?@action=redirect&bpo=28929]: Link the documentation to its source file on GitHub.
- [bpo-25008](https://bugs.python.org/issue?@action=redirect&bpo=25008) [https://bugs.python.org/issue?@action=redirect&bpo=25008]: Document smtpd.py as effectively deprecated and add a pointer to aiosmtpd, a third-party asyncio-based replacement.
- [bpo-26355](https://bugs.python.org/issue?@action=redirect&bpo=26355) [https://bugs.python.org/issue?@action=redirect&bpo=26355]: Add canonical header link on each page to corresponding major version of the documentation. Patch by Matthias Bussonnier.
- [bpo-29349](https://bugs.python.org/issue?@action=redirect&bpo=29349) [https://bugs.python.org/issue?@action=redirect&bpo=29349]: Fix Python 2 syntax in code for building the documentation.

## Tests

- [bpo-30822](https://bugs.python.org/issue?@action=redirect&bpo=30822) [https://bugs.python.org/issue?@action=redirect&bpo=30822]: Fix regrtest command line parser to allow passing -u extralargefile to run test\_zipfile64.
- [bpo-30383](https://bugs.python.org/issue?@action=redirect&bpo=30383) [https://bugs.python.org/issue?@action=redirect&bpo=30383]: regrtest: Enhance regrtest and backport features from the master branch. Add options: -coverage, -testdir, -list-tests (list test files, don't run them), -list-cases (list test identifiers, don't run them, [bpo-30523](https://bugs.python.org/issue?@action=redirect&bpo=30523) [https://bugs.python.org/issue?@action=redirect&bpo=30523]), -

matchfile (load a list of test filters from a text file, [bpo-30540](https://bugs.python.org/issue?@action=redirect&bpo=30540) [https://bugs.python.org/issue?@action=redirect&bpo=30540]), –slowest (alias to –slow). Enhance output: add timestamp, test result, currently running tests, “Tests result: xxx” summary with total duration, etc. Fix reference leak hunting in regrtest, –huntrleaks: regrtest now warms up caches, create explicitly all internal singletons which are created on demand to prevent false positives when checking for reference leaks. ([bpo-30675](https://bugs.python.org/issue?@action=redirect&bpo=30675) [https://bugs.python.org/issue?@action=redirect&bpo=30675])).

- [bpo-30357](https://bugs.python.org/issue?@action=redirect&bpo=30357) [https://bugs.python.org/issue?@action=redirect&bpo=30357]: test\_thread: setUp() now uses support.threading\_setup() and support.threading\_cleanup() to wait until threads complete to avoid random side effects on following tests. Initial patch written by Grzegorz Grzywacz.
- [bpo-28087](https://bugs.python.org/issue?@action=redirect&bpo=28087) [https://bugs.python.org/issue?@action=redirect&bpo=28087]: Skip test\_asyncore and test\_eintr poll failures on macOS. Skip some tests of select.poll when running on macOS due to unresolved issues with the underlying system poll function on some macOS versions.
- [bpo-30197](https://bugs.python.org/issue?@action=redirect&bpo=30197) [https://bugs.python.org/issue?@action=redirect&bpo=30197]: Enhanced functions swap\_attr() and swap\_item() in the test.support module. They now work when delete replaced attribute or item inside the with statement. The old value of the attribute or item (or None if it doesn't exist) now will be assigned to the target of the “as” clause, if there is one.
- [bpo-29571](https://bugs.python.org/issue?@action=redirect&bpo=29571) [https://bugs.python.org/issue?@action=redirect&bpo=29571]: to match the behaviour of the re.LOCALE flag, test\_re.test\_locale\_flag now uses locale.getpreferredencoding(False) to determine the candidate encoding for the test regex (allowing it to correctly skip the test when the default locale encoding is a multi-byte encoding)

## Build

- [bpo-29243](https://bugs.python.org/issue?@action=redirect&bpo=29243) [https://bugs.python.org/issue?@action=redirect&bpo=29243]: Prevent unnecessary rebuilding of Python during make test, make install and some other

make targets when configured with `--enable-optimizations`.

- [bpo-23404](https://bugs.python.org/issue?@action=redirect&bpo=23404) [https://bugs.python.org/issue?@action=redirect&bpo=23404]: Don't regenerate generated files based on file modification time anymore: the action is now explicit. Replace `make touch` with `make regen-all`.
- [bpo-29643](https://bugs.python.org/issue?@action=redirect&bpo=29643) [https://bugs.python.org/issue?@action=redirect&bpo=29643]: Fix `--enable-optimization` didn't work.

## Windows

- [bpo-30687](https://bugs.python.org/issue?@action=redirect&bpo=30687) [https://bugs.python.org/issue?@action=redirect&bpo=30687]: Locate `msbuild.exe` on Windows when building rather than `vcvarsall.bat`
- [bpo-29392](https://bugs.python.org/issue?@action=redirect&bpo=29392) [https://bugs.python.org/issue?@action=redirect&bpo=29392]: Prevent crash when passing invalid arguments into `msvcrt` module.

## C API

- [bpo-27867](https://bugs.python.org/issue?@action=redirect&bpo=27867) [https://bugs.python.org/issue?@action=redirect&bpo=27867]: Function `PySlice_GetIndicesEx()` is replaced with a macro if `Py_LIMITED_API` is set to the value between `0x03050400` and `0x03060000` (not including) or `0x03060100` or higher.
- [bpo-29083](https://bugs.python.org/issue?@action=redirect&bpo=29083) [https://bugs.python.org/issue?@action=redirect&bpo=29083]: Fixed the declaration of some public API functions. `PyArg_VaParse()` and `PyArg_VaParseTupleAndKeywords()` were not available in limited API. `PyArg_ValidateKeywordArguments()`, `PyArg_UnpackTuple()` and `Py_BuildValue()` were not available in limited API of version `< 3.3` when `PY_SSIZE_T_CLEAN` is defined.

## Python 3.5.3 final

*Release date: 2017-01-17*

There were no code changes between 3.5.3rc1 and 3.5.3 final.

# Python 3.5.3 release candidate 1

*Release date: 2017-01-02*

## Security

- [bpo-27278](https://bugs.python.org/issue?@action=redirect&bpo=27278) [https://bugs.python.org/issue?@action=redirect&bpo=27278]: Fix `os.urandom()` implementation using `getrandom()` on Linux. Truncate size to `INT_MAX` and loop until we collected enough random bytes, instead of casting a directly `Py_ssize_t` to `int`.
- [bpo-22636](https://bugs.python.org/issue?@action=redirect&bpo=22636) [https://bugs.python.org/issue?@action=redirect&bpo=22636]: Avoid shell injection problems with `ctypes.util.find_library()`.

## Core and Builtins

- [bpo-29073](https://bugs.python.org/issue?@action=redirect&bpo=29073) [https://bugs.python.org/issue?@action=redirect&bpo=29073]: bytearray formatting no longer truncates on first null byte.
- [bpo-28932](https://bugs.python.org/issue?@action=redirect&bpo=28932) [https://bugs.python.org/issue?@action=redirect&bpo=28932]: Do not include `<sys/random.h>` if it does not exist.
- [bpo-28147](https://bugs.python.org/issue?@action=redirect&bpo=28147) [https://bugs.python.org/issue?@action=redirect&bpo=28147]: Fix a memory leak in split-table dictionaries: `setattr()` must not convert combined table into split table.
- [bpo-25677](https://bugs.python.org/issue?@action=redirect&bpo=25677) [https://bugs.python.org/issue?@action=redirect&bpo=25677]: Correct the positioning of the syntax error caret for indented blocks. Based on patch by Michael Layzell.
- [bpo-29000](https://bugs.python.org/issue?@action=redirect&bpo=29000) [https://bugs.python.org/issue?@action=redirect&bpo=29000]: Fixed bytes formatting of octals with zero padding in alternate form.
- [bpo-28512](https://bugs.python.org/issue?@action=redirect&bpo=28512) [https://bugs.python.org/issue?@action=redirect&bpo=28512]: Fixed setting the offset attribute of `SyntaxError` by `PyErr_SyntaxLocationEx()` and

PyErr\_SyntaxLocationObject).

- [bpo-28991](https://bugs.python.org/issue?@action=redirect&bpo=28991) [https://bugs.python.org/issue?@action=redirect&bpo=28991]: functools.lru\_cache() was susceptible to an obscure reentrancy bug caused by a monkey-patched len() function.
- [bpo-28648](https://bugs.python.org/issue?@action=redirect&bpo=28648) [https://bugs.python.org/issue?@action=redirect&bpo=28648]: Fixed crash in Py\_DecodeLocale() in debug build on Mac OS X when decode astral characters. Patch by Xiang Zhang.
- [bpo-19398](https://bugs.python.org/issue?@action=redirect&bpo=19398) [https://bugs.python.org/issue?@action=redirect&bpo=19398]: Extra slash no longer added to sys.path components in case of empty compile-time PYTHONPATH components.
- [bpo-28426](https://bugs.python.org/issue?@action=redirect&bpo=28426) [https://bugs.python.org/issue?@action=redirect&bpo=28426]: Fixed potential crash in PyUnicode\_AsDecodedObject() in debug build.
- [bpo-23782](https://bugs.python.org/issue?@action=redirect&bpo=23782) [https://bugs.python.org/issue?@action=redirect&bpo=23782]: Fixed possible memory leak in \_PyTraceback\_Add() and exception loss in PyTraceBack\_Here().
- [bpo-28379](https://bugs.python.org/issue?@action=redirect&bpo=28379) [https://bugs.python.org/issue?@action=redirect&bpo=28379]: Added sanity checks and tests for PyUnicode\_CopyCharacters(). Patch by Xiang Zhang.
- [bpo-28376](https://bugs.python.org/issue?@action=redirect&bpo=28376) [https://bugs.python.org/issue?@action=redirect&bpo=28376]: The type of long range iterator is now registered as Iterator. Patch by Oren Milman.
- [bpo-28376](https://bugs.python.org/issue?@action=redirect&bpo=28376) [https://bugs.python.org/issue?@action=redirect&bpo=28376]: The constructor of range\_iterator now checks that step is not 0. Patch by Oren Milman.
- [bpo-26906](https://bugs.python.org/issue?@action=redirect&bpo=26906) [https://bugs.python.org/issue?@action=redirect&bpo=26906]: Resolving special methods of uninitialized type now causes implicit initialization of the type instead of a fail.
- [bpo-18287](https://bugs.python.org/issue?@action=redirect&bpo=18287) [https://bugs.python.org/issue?@action=redirect&bpo=18287]: PyType\_Ready() now checks that tp\_name is not NULL. Original patch by Niklas Koep.
- [bpo-24098](https://bugs.python.org/issue?@action=redirect&bpo=24098) [https://bugs.python.org/issue?@action=redirect&bpo=24098]: Fixed possible crash when AST is changed in process of compiling it.
- [bpo-28350](https://bugs.python.org/issue?@action=redirect&bpo=28350) [https://bugs.python.org/issue?@action=redirect&bpo=28350]

@action=redirect&bpo=28350]: String constants with null character no longer interned.

- [bpo-26617](https://bugs.python.org/issue?@action=redirect&bpo=26617) [https://bugs.python.org/issue?@action=redirect&bpo=26617]: Fix crash when GC runs during weakref callbacks.
- [bpo-27942](https://bugs.python.org/issue?@action=redirect&bpo=27942) [https://bugs.python.org/issue?@action=redirect&bpo=27942]: String constants now interned recursively in tuples and frozensets.
- [bpo-21578](https://bugs.python.org/issue?@action=redirect&bpo=21578) [https://bugs.python.org/issue?@action=redirect&bpo=21578]: Fixed misleading error message when ImportError called with invalid keyword args.
- [bpo-28203](https://bugs.python.org/issue?@action=redirect&bpo=28203) [https://bugs.python.org/issue?@action=redirect&bpo=28203]: Fix incorrect type in error message from `complex(1.0, {2:3})`. Patch by Soumya Sharma.
- [bpo-27955](https://bugs.python.org/issue?@action=redirect&bpo=27955) [https://bugs.python.org/issue?@action=redirect&bpo=27955]: Fallback on reading /dev/urandom device when the getrandom() syscall fails with EPERM, for example when blocked by SECCOMP.
- [bpo-28131](https://bugs.python.org/issue?@action=redirect&bpo=28131) [https://bugs.python.org/issue?@action=redirect&bpo=28131]: Fix a regression in zipimport's `compile_source()`. zipimport should use the same optimization level as the interpreter.
- [bpo-25221](https://bugs.python.org/issue?@action=redirect&bpo=25221) [https://bugs.python.org/issue?@action=redirect&bpo=25221]: Fix corrupted result from `PyLong_FromLong(0)` when Python is compiled with `NSMALLPOSINTS = 0`.
- [bpo-25758](https://bugs.python.org/issue?@action=redirect&bpo=25758) [https://bugs.python.org/issue?@action=redirect&bpo=25758]: Prevents zipimport from unnecessarily encoding a filename (patch by Eryk Sun)
- [bpo-28189](https://bugs.python.org/issue?@action=redirect&bpo=28189) [https://bugs.python.org/issue?@action=redirect&bpo=28189]: `dictitems_contains` no longer swallows compare errors. (Patch by Xiang Zhang)
- [bpo-27812](https://bugs.python.org/issue?@action=redirect&bpo=27812) [https://bugs.python.org/issue?@action=redirect&bpo=27812]: Properly clear out a generator's frame's backreference to the generator to prevent crashes in `frame.clear()`.
- [bpo-27811](https://bugs.python.org/issue?@action=redirect&bpo=27811) [https://bugs.python.org/issue?@action=redirect&bpo=27811]: Fix a crash when a coroutine that has not been awaited is finalized with `warnings-as-errors`

enabled.

- [bpo-27587](https://bugs.python.org/issue?@action=redirect&bpo=27587) [https://bugs.python.org/issue?@action=redirect&bpo=27587]: Fix another issue found by PVS-Studio: Null pointer check after use of ‘def’ in `_PyState_AddModule()`. Initial patch by Christian Heimes.
- [bpo-26020](https://bugs.python.org/issue?@action=redirect&bpo=26020) [https://bugs.python.org/issue?@action=redirect&bpo=26020]: set literal evaluation order did not match documented behaviour.
- [bpo-27782](https://bugs.python.org/issue?@action=redirect&bpo=27782) [https://bugs.python.org/issue?@action=redirect&bpo=27782]: Multi-phase extension module import now correctly allows the `m_methods` field to be used to add module level functions to instances of non-module types returned from `Py_create_mod`. Patch by Xiang Zhang.
- [bpo-27936](https://bugs.python.org/issue?@action=redirect&bpo=27936) [https://bugs.python.org/issue?@action=redirect&bpo=27936]: The `round()` function accepted a second `None` argument for some types but not for others. Fixed the inconsistency by accepting `None` for all numeric types.
- [bpo-27487](https://bugs.python.org/issue?@action=redirect&bpo=27487) [https://bugs.python.org/issue?@action=redirect&bpo=27487]: Warn if a submodule argument to “python -m” or `runpy.run_module()` is found in `sys.modules` after parent packages are imported, but before the submodule is executed.
- [bpo-27558](https://bugs.python.org/issue?@action=redirect&bpo=27558) [https://bugs.python.org/issue?@action=redirect&bpo=27558]: Fix a `SystemError` in the implementation of “raise” statement. In a brand new thread, raise a `RuntimeError` since there is no active exception to reraise. Patch written by Xiang Zhang.
- [bpo-27419](https://bugs.python.org/issue?@action=redirect&bpo=27419) [https://bugs.python.org/issue?@action=redirect&bpo=27419]: Standard `__import__()` no longer look up “`__import__`” in globals or builtins for importing submodules or “from import”. Fixed handling an error of non-string package name.
- [bpo-27083](https://bugs.python.org/issue?@action=redirect&bpo=27083) [https://bugs.python.org/issue?@action=redirect&bpo=27083]: Respect the `PYTHONCASEOK` environment variable under Windows.
- [bpo-27514](https://bugs.python.org/issue?@action=redirect&bpo=27514) [https://bugs.python.org/issue?@action=redirect&bpo=27514]: Make having too many statically nested blocks a `SyntaxError` instead of `SystemError`.

- [bpo-27473](https://bugs.python.org/issue?@action=redirect&bpo=27473) [https://bugs.python.org/issue?@action=redirect&bpo=27473]: Fixed possible integer overflow in bytes and bytearray concatenations. Patch by Xiang Zhang.
- [bpo-27507](https://bugs.python.org/issue?@action=redirect&bpo=27507) [https://bugs.python.org/issue?@action=redirect&bpo=27507]: Add integer overflow check in bytearray.extend(). Patch by Xiang Zhang.
- [bpo-27581](https://bugs.python.org/issue?@action=redirect&bpo=27581) [https://bugs.python.org/issue?@action=redirect&bpo=27581]: Don't rely on wrapping for overflow check in PySequence\_Tuple(). Patch by Xiang Zhang.
- [bpo-27443](https://bugs.python.org/issue?@action=redirect&bpo=27443) [https://bugs.python.org/issue?@action=redirect&bpo=27443]: `__length_hint__()` of bytearray iterators no longer return a negative integer for a resized bytearray.
- [bpo-27942](https://bugs.python.org/issue?@action=redirect&bpo=27942) [https://bugs.python.org/issue?@action=redirect&bpo=27942]: Fix memory leak in codeobject.c

## Library

- [bpo-15812](https://bugs.python.org/issue?@action=redirect&bpo=15812) [https://bugs.python.org/issue?@action=redirect&bpo=15812]: `inspect.getframeinfo()` now correctly shows the first line of a context. Patch by Sam Breese.
- [bpo-29094](https://bugs.python.org/issue?@action=redirect&bpo=29094) [https://bugs.python.org/issue?@action=redirect&bpo=29094]: Offsets in a ZIP file created with `extern` file object and modes “w” and “x” now are relative to the start of the file.
- [bpo-13051](https://bugs.python.org/issue?@action=redirect&bpo=13051) [https://bugs.python.org/issue?@action=redirect&bpo=13051]: Fixed recursion errors in large or resized `curses.textpad.Textbox`. Based on patch by Tycho Andersen.
- [bpo-29119](https://bugs.python.org/issue?@action=redirect&bpo=29119) [https://bugs.python.org/issue?@action=redirect&bpo=29119]: Fix weakrefs in the pure python version of `collections.OrderedDict.move_to_end()` method. Contributed by Andra Bogildea.
- [bpo-9770](https://bugs.python.org/issue?@action=redirect&bpo=9770) [https://bugs.python.org/issue?@action=redirect&bpo=9770]: `curses.ascii` predicates now work correctly with negative integers.
- [bpo-28427](https://bugs.python.org/issue?@action=redirect&bpo=28427) [https://bugs.python.org/issue?@action=redirect&bpo=28427]: old keys should not remove new values from `WeakValueDictionary` when collecting from

another thread.

- [bpo-28923](https://bugs.python.org/issue?@action=redirect&bpo=28923) [https://bugs.python.org/issue?@action=redirect&bpo=28923]: Remove editor artifacts from Tix.py.
- [bpo-28871](https://bugs.python.org/issue?@action=redirect&bpo=28871) [https://bugs.python.org/issue?@action=redirect&bpo=28871]: Fixed a crash when deallocate deep ElementTree.
- [bpo-19542](https://bugs.python.org/issue?@action=redirect&bpo=19542) [https://bugs.python.org/issue?@action=redirect&bpo=19542]: Fix bugs in WeakValueDictionary.setdefault() and WeakValueDictionary.pop() when a GC collection happens in another thread.
- [bpo-20191](https://bugs.python.org/issue?@action=redirect&bpo=20191) [https://bugs.python.org/issue?@action=redirect&bpo=20191]: Fixed a crash in resource.prlimit() when pass a sequence that doesn't own its elements as limits.
- [bpo-28779](https://bugs.python.org/issue?@action=redirect&bpo=28779) [https://bugs.python.org/issue?@action=redirect&bpo=28779]: multiprocessing.set\_forkserver\_preload() would crash the forking process if a preloaded module instantiated some multiprocessing objects such as locks.
- [bpo-28847](https://bugs.python.org/issue?@action=redirect&bpo=28847) [https://bugs.python.org/issue?@action=redirect&bpo=28847]: dbm.dumb now supports reading read-only files and no longer writes the index file when it is not changed.
- [bpo-25659](https://bugs.python.org/issue?@action=redirect&bpo=25659) [https://bugs.python.org/issue?@action=redirect&bpo=25659]: In ctypes, prevent a crash calling the from\_buffer() and from\_buffer\_copy() methods on abstract classes like Array.
- [bpo-28732](https://bugs.python.org/issue?@action=redirect&bpo=28732) [https://bugs.python.org/issue?@action=redirect&bpo=28732]: Fix crash in os.spawnv() with no elements in args
- [bpo-28485](https://bugs.python.org/issue?@action=redirect&bpo=28485) [https://bugs.python.org/issue?@action=redirect&bpo=28485]: Always raise ValueError for negative compileall.compile\_dir(workers=...) parameter, even when multithreading is unavailable.
- [bpo-28387](https://bugs.python.org/issue?@action=redirect&bpo=28387) [https://bugs.python.org/issue?@action=redirect&bpo=28387]: Fixed possible crash in \_io.TextIOWrapper deallocator when the garbage collector is invoked in other thread. Based on patch by Sebastian Cufre.
- [bpo-27517](https://bugs.python.org/issue?@action=redirect&bpo=27517) [https://bugs.python.org/issue?@action=redirect&bpo=27517]

@action=redirect&bpo=27517]: LZMA compressor and decompressor no longer raise exceptions if given empty data twice. Patch by Benjamin Fogle.

- [bpo-28549](https://bugs.python.org/issue?@action=redirect&bpo=28549) [https://bugs.python.org/issue?@action=redirect&bpo=28549]: Fixed segfault in curses's addch() with ncurses6.
- [bpo-28449](https://bugs.python.org/issue?@action=redirect&bpo=28449) [https://bugs.python.org/issue?@action=redirect&bpo=28449]: tarfile.open() with mode "r" or "r:" now tries to open a tar file with compression before trying to open it without compression. Otherwise it had 50% chance failed with ignore\_zeros = True.
- [bpo-23262](https://bugs.python.org/issue?@action=redirect&bpo=23262) [https://bugs.python.org/issue?@action=redirect&bpo=23262]: The webbrowser module now supports Firefox 36+ and derived browsers. Based on patch by Oleg Broytman.
- [bpo-27939](https://bugs.python.org/issue?@action=redirect&bpo=27939) [https://bugs.python.org/issue?@action=redirect&bpo=27939]: Fixed bugs in tkinter.ttk.LabeledScale and tkinter.Scale caused by representing the scale as float value internally in Tk. tkinter.IntVar now works if float value is set to underlying Tk variable.
- [bpo-28255](https://bugs.python.org/issue?@action=redirect&bpo=28255) [https://bugs.python.org/issue?@action=redirect&bpo=28255]: calendar.TextCalendar().prmonth() no longer prints a space at the start of new line after printing a month's calendar. Patch by Xiang Zhang.
- [bpo-20491](https://bugs.python.org/issue?@action=redirect&bpo=20491) [https://bugs.python.org/issue?@action=redirect&bpo=20491]: The textwrap.TextWrapper class now honors non-breaking spaces. Based on patch by Kaarle Ritvanen.
- [bpo-28353](https://bugs.python.org/issue?@action=redirect&bpo=28353) [https://bugs.python.org/issue?@action=redirect&bpo=28353]: os.fwalk() no longer fails on broken links.
- [bpo-25464](https://bugs.python.org/issue?@action=redirect&bpo=25464) [https://bugs.python.org/issue?@action=redirect&bpo=25464]: Fixed HList.header\_exists() in tkinter.tix module by addin a workaround to Tix library bug.
- [bpo-28488](https://bugs.python.org/issue?@action=redirect&bpo=28488) [https://bugs.python.org/issue?@action=redirect&bpo=28488]: shutil.make\_archive() no longer add entry "." to ZIP archive.
- [bpo-24452](https://bugs.python.org/issue?@action=redirect&bpo=24452) [https://bugs.python.org/issue?@action=redirect&bpo=24452]

@action=redirect&bpo=24452]: Make webbrowser support Chrome on Mac OS X.

- [bpo-20766](https://bugs.python.org/issue?@action=redirect&bpo=20766) [https://bugs.python.org/issue?@action=redirect&bpo=20766]: Fix references leaked by pdb in the handling of SIGINT handlers.
- [bpo-26293](https://bugs.python.org/issue?@action=redirect&bpo=26293) [https://bugs.python.org/issue?@action=redirect&bpo=26293]: Fixed writing ZIP files that starts not from the start of the file. Offsets in ZIP file now are relative to the start of the archive in conforming to the specification.
- [bpo-28321](https://bugs.python.org/issue?@action=redirect&bpo=28321) [https://bugs.python.org/issue?@action=redirect&bpo=28321]: Fixed writing non-BMP characters with binary format in plistlib.
- [bpo-28322](https://bugs.python.org/issue?@action=redirect&bpo=28322) [https://bugs.python.org/issue?@action=redirect&bpo=28322]: Fixed possible crashes when unpickle itertools objects from incorrect pickle data. Based on patch by John Leitch.
- Fix possible integer overflows and crashes in the mmap module with unusual usage patterns.
- [bpo-1703178](https://bugs.python.org/issue?@action=redirect&bpo=1703178) [https://bugs.python.org/issue?@action=redirect&bpo=1703178]: Fix the ability to pass the -link-objects option to the distutils build\_ext command.
- [bpo-28253](https://bugs.python.org/issue?@action=redirect&bpo=28253) [https://bugs.python.org/issue?@action=redirect&bpo=28253]: Fixed calendar functions for extreme months: 0001-01 and 9999-12. Methods itermonthdays() and itermonthdays2() are reimplemented so that they don't call itermonthdates() which can cause datetime.date under/overflow.
- [bpo-28275](https://bugs.python.org/issue?@action=redirect&bpo=28275) [https://bugs.python.org/issue?@action=redirect&bpo=28275]: Fixed possible use after free in the decompress() methods of the LZMADecompressor and BZ2Decompressor classes. Original patch by John Leitch.
- [bpo-27897](https://bugs.python.org/issue?@action=redirect&bpo=27897) [https://bugs.python.org/issue?@action=redirect&bpo=27897]: Fixed possible crash in sqlite3.Connection.create\_collation() if pass invalid string-like object as a name. Patch by Xiang Zhang.
- [bpo-18893](https://bugs.python.org/issue?@action=redirect&bpo=18893) [https://bugs.python.org/issue?@action=redirect&bpo=18893]: Fix invalid exception handling in Lib/ctypes/macholib/dyld.py. Patch by Madison May.
- [bpo-27611](https://bugs.python.org/issue?@action=redirect&bpo=27611) [https://bugs.python.org/issue?@action=redirect&bpo=27611]

@action=redirect&bpo=27611]: Fixed support of default root window in the tkinter.tix module.

- [bpo-27348](https://bugs.python.org/issue?@action=redirect&bpo=27348) [https://bugs.python.org/issue?@action=redirect&bpo=27348]: In the traceback module, restore the formatting of exception messages like “Exception: None”. This fixes a regression introduced in 3.5a2.
- [bpo-25651](https://bugs.python.org/issue?@action=redirect&bpo=25651) [https://bugs.python.org/issue?@action=redirect&bpo=25651]: Allow falsy values to be used for msg parameter of subTest().
- [bpo-27932](https://bugs.python.org/issue?@action=redirect&bpo=27932) [https://bugs.python.org/issue?@action=redirect&bpo=27932]: Prevent memory leak in win32\_ver().
- Fix UnboundLocalError in socket.\_sendfile\_use\_sendfile.
- [bpo-28075](https://bugs.python.org/issue?@action=redirect&bpo=28075) [https://bugs.python.org/issue?@action=redirect&bpo=28075]: Check for ERROR\_ACCESS\_DENIED in Windows implementation of os.stat(). Patch by Eryk Sun.
- [bpo-25270](https://bugs.python.org/issue?@action=redirect&bpo=25270) [https://bugs.python.org/issue?@action=redirect&bpo=25270]: Prevent codecs.escape\_encode() from raising SystemError when an empty bytestring is passed.
- [bpo-28181](https://bugs.python.org/issue?@action=redirect&bpo=28181) [https://bugs.python.org/issue?@action=redirect&bpo=28181]: Get antigravity over HTTPS. Patch by Kaartic Sivaraam.
- [bpo-25895](https://bugs.python.org/issue?@action=redirect&bpo=25895) [https://bugs.python.org/issue?@action=redirect&bpo=25895]: Enable WebSocket URL schemes in urllib.parse.urljoin. Patch by Gergely Imreh and Markus Holtermann.
- [bpo-27599](https://bugs.python.org/issue?@action=redirect&bpo=27599) [https://bugs.python.org/issue?@action=redirect&bpo=27599]: Fixed buffer overrun in binascii.b2a\_qp() and binascii.a2b\_qp().
- [bpo-19003](https://bugs.python.org/issue?@action=redirect&bpo=19003) [https://bugs.python.org/issue?@action=redirect&bpo=19003]: m email.generator now replaces only \r and/or \n line endings, per the RFC, instead of all unicode line endings.
- [bpo-28019](https://bugs.python.org/issue?@action=redirect&bpo=28019) [https://bugs.python.org/issue?@action=redirect&bpo=28019]: itertools.count() no longer rounds non-integer step in range between 1.0 and 2.0 to 1.
- [bpo-25969](https://bugs.python.org/issue?@action=redirect&bpo=25969) [https://bugs.python.org/issue?@action=redirect&bpo=25969]: Update the lib2to3 grammar to handle the unpacking generalizations added in 3.5.

- [bpo-14977](https://bugs.python.org/issue?@action=redirect&bpo=14977) [https://bugs.python.org/issue?@action=redirect&bpo=14977]: mailcap now respects the order of the lines in the mailcap files (“first match”), as required by RFC 1542. Patch by Michael Lazar.
- [bpo-24594](https://bugs.python.org/issue?@action=redirect&bpo=24594) [https://bugs.python.org/issue?@action=redirect&bpo=24594]: Validates persist parameter when opening MSI database
- [bpo-17582](https://bugs.python.org/issue?@action=redirect&bpo=17582) [https://bugs.python.org/issue?@action=redirect&bpo=17582]: xml.etree.ElementTree nows preserves whitespaces in attributes (Patch by Duane Griffin. Reviewed and approved by Stefan Behnel.)
- [bpo-28047](https://bugs.python.org/issue?@action=redirect&bpo=28047) [https://bugs.python.org/issue?@action=redirect&bpo=28047]: Fixed calculation of line length used for the base64 CTE in the new email policies.
- [bpo-27445](https://bugs.python.org/issue?@action=redirect&bpo=27445) [https://bugs.python.org/issue?@action=redirect&bpo=27445]: Don’t pass str(\_charset) to MIMEText.set\_payload(). Patch by Claude Paroz.
- [bpo-22450](https://bugs.python.org/issue?@action=redirect&bpo=22450) [https://bugs.python.org/issue?@action=redirect&bpo=22450]: urllib now includes an `Accept : */*` header among the default headers. This makes the results of REST API requests more consistent and predictable especially when proxy servers are involved.
- `lib2to3.pgen3.driver.load_grammar()` now creates a stable cache file between runs given the same `Grammar.txt` input regardless of the hash randomization setting.
- [bpo-27570](https://bugs.python.org/issue?@action=redirect&bpo=27570) [https://bugs.python.org/issue?@action=redirect&bpo=27570]: Avoid zero-length `memcpy()` etc calls with null source pointers in the “ctypes” and “array” modules.
- [bpo-22233](https://bugs.python.org/issue?@action=redirect&bpo=22233) [https://bugs.python.org/issue?@action=redirect&bpo=22233]: Break email header lines *only* on the RFC specified CR and LF characters, not on arbitrary unicode line breaks. This also fixes a bug in HTTP header parsing.
- [bpo-27988](https://bugs.python.org/issue?@action=redirect&bpo=27988) [https://bugs.python.org/issue?@action=redirect&bpo=27988]: Fix email `iter_attachments` incorrect mutation of payload list.
- [bpo-27691](https://bugs.python.org/issue?@action=redirect&bpo=27691) [https://bugs.python.org/issue?@action=redirect&bpo=27691]: Fix `ssl` module’s parsing of `GEN_RID` subject alternative name fields in X.509 certs.

- [bpo-27850](https://bugs.python.org/issue?@action=redirect&bpo=27850) [https://bugs.python.org/issue?@action=redirect&bpo=27850]: Remove 3DES from ssl module's default cipher list to counter measure sweet32 attack (CVE-2016-2183).
- [bpo-27766](https://bugs.python.org/issue?@action=redirect&bpo=27766) [https://bugs.python.org/issue?@action=redirect&bpo=27766]: Add ChaCha20 Poly1305 to ssl module's default cipher list. (Required OpenSSL 1.1.0 or LibreSSL).
- [bpo-26470](https://bugs.python.org/issue?@action=redirect&bpo=26470) [https://bugs.python.org/issue?@action=redirect&bpo=26470]: Port ssl and hashlib module to OpenSSL 1.1.0.
- Remove support for passing a file descriptor to os.access. It never worked but previously didn't raise.
- [bpo-12885](https://bugs.python.org/issue?@action=redirect&bpo=12885) [https://bugs.python.org/issue?@action=redirect&bpo=12885]: Fix error when distutils encounters symlink.
- [bpo-27881](https://bugs.python.org/issue?@action=redirect&bpo=27881) [https://bugs.python.org/issue?@action=redirect&bpo=27881]: Fixed possible bugs when setting sqlite3.Connection.isolation\_level. Based on patch by Xiang Zhang.
- [bpo-27861](https://bugs.python.org/issue?@action=redirect&bpo=27861) [https://bugs.python.org/issue?@action=redirect&bpo=27861]: Fixed a crash in sqlite3.Connection.cursor() when a factory creates not a cursor. Patch by Xiang Zhang.
- [bpo-19884](https://bugs.python.org/issue?@action=redirect&bpo=19884) [https://bugs.python.org/issue?@action=redirect&bpo=19884]: Avoid spurious output on OS X with Gnu Readline.
- [bpo-27706](https://bugs.python.org/issue?@action=redirect&bpo=27706) [https://bugs.python.org/issue?@action=redirect&bpo=27706]: Restore deterministic behavior of random.Random().seed() for string seeds using seeding version 1. Allows sequences of calls to random() to exactly match those obtained in Python 2. Patch by Nofar Schnider.
- [bpo-10513](https://bugs.python.org/issue?@action=redirect&bpo=10513) [https://bugs.python.org/issue?@action=redirect&bpo=10513]: Fix a regression in Connection.commit(). Statements should not be reset after a commit.
- A new version of typing.py from <https://github.com/python/typing>: Collection (only for 3.6) ([bpo-27598](https://bugs.python.org/issue?@action=redirect&bpo=27598) [https://bugs.python.org/issue?@action=redirect&bpo=27598]). Add FrozenSet to `_all_` (upstream #261). Fix crash in `_get_type_vars()`

(upstream #259). Remove the dict constraint in ForwardRef.\_eval\_type (upstream #252).

- [bpo-27539](https://bugs.python.org/issue?@action=redirect&bpo=27539) [https://bugs.python.org/issue?@action=redirect&bpo=27539]: Fix unnormalised Fraction.\_\_pow\_\_ result in the case of negative exponent and negative base.
- [bpo-21718](https://bugs.python.org/issue?@action=redirect&bpo=21718) [https://bugs.python.org/issue?@action=redirect&bpo=21718]: cursor.description is now available for queries using CTEs.
- [bpo-2466](https://bugs.python.org/issue?@action=redirect&bpo=2466) [https://bugs.python.org/issue?@action=redirect&bpo=2466]: posixpath.ismount now correctly recognizes mount points which the user does not have permission to access.
- [bpo-27773](https://bugs.python.org/issue?@action=redirect&bpo=27773) [https://bugs.python.org/issue?@action=redirect&bpo=27773]: Correct some memory management errors server\_hostname in \_ssl.wrap\_socket().
- [bpo-26750](https://bugs.python.org/issue?@action=redirect&bpo=26750) [https://bugs.python.org/issue?@action=redirect&bpo=26750]: unittest.mock.create\_autospec() now works properly for subclasses of property() and other data descriptors.
- In the curses module, raise an error if window.getstr() or window.instr() is passed a negative value.
- [bpo-27783](https://bugs.python.org/issue?@action=redirect&bpo=27783) [https://bugs.python.org/issue?@action=redirect&bpo=27783]: Fix possible usage of uninitialized memory in operator.methodcaller.
- [bpo-27774](https://bugs.python.org/issue?@action=redirect&bpo=27774) [https://bugs.python.org/issue?@action=redirect&bpo=27774]: Fix possible Py\_DECREF on unowned object in \_sre.
- [bpo-27760](https://bugs.python.org/issue?@action=redirect&bpo=27760) [https://bugs.python.org/issue?@action=redirect&bpo=27760]: Fix possible integer overflow in binascii.b2a\_qp.
- [bpo-27758](https://bugs.python.org/issue?@action=redirect&bpo=27758) [https://bugs.python.org/issue?@action=redirect&bpo=27758]: Fix possible integer overflow in the \_csv module for large record lengths.
- [bpo-27568](https://bugs.python.org/issue?@action=redirect&bpo=27568) [https://bugs.python.org/issue?@action=redirect&bpo=27568]: Prevent HTTPoxy attack (CVE-2016-1000110). Ignore the HTTP\_PROXY variable when REQUEST\_METHOD environment is set, which indicates that the script is in CGI mode.
- [bpo-27656](https://bugs.python.org/issue?@action=redirect&bpo=27656) [https://bugs.python.org/issue?@action=redirect&bpo=27656]: Do not assume sched.h defines

any `SCHED_*` constants.

- [bpo-27130](https://bugs.python.org/issue?@action=redirect&bpo=27130) [https://bugs.python.org/issue?@action=redirect&bpo=27130]: In the “zlib” module, fix handling of large buffers (typically 4 GiB) when compressing and decompressing. Previously, inputs were limited to 4 GiB, and compression and decompression operations did not properly handle results of 4 GiB.
- [bpo-27533](https://bugs.python.org/issue?@action=redirect&bpo=27533) [https://bugs.python.org/issue?@action=redirect&bpo=27533]: Release GIL in `nt._isdir`
- [bpo-17711](https://bugs.python.org/issue?@action=redirect&bpo=17711) [https://bugs.python.org/issue?@action=redirect&bpo=17711]: Fixed unpickling by the persistent ID with protocol 0. Original patch by Alexandre Vassalotti.
- [bpo-27522](https://bugs.python.org/issue?@action=redirect&bpo=27522) [https://bugs.python.org/issue?@action=redirect&bpo=27522]: Avoid an unintentional reference cycle in `email.feedparser`.
- [bpo-26844](https://bugs.python.org/issue?@action=redirect&bpo=26844) [https://bugs.python.org/issue?@action=redirect&bpo=26844]: Fix error message for `imp.find_module()` to refer to ‘path’ instead of ‘name’. Patch by Lev Maximov.
- [bpo-23804](https://bugs.python.org/issue?@action=redirect&bpo=23804) [https://bugs.python.org/issue?@action=redirect&bpo=23804]: Fix SSL zero-length `recv()` calls to not block and not raise an error about unclean EOF.
- [bpo-27466](https://bugs.python.org/issue?@action=redirect&bpo=27466) [https://bugs.python.org/issue?@action=redirect&bpo=27466]: Change time format returned by `http.cookie.time2netscape`, confirming the netscape cookie format and making it consistent with documentation.
- [bpo-26664](https://bugs.python.org/issue?@action=redirect&bpo=26664) [https://bugs.python.org/issue?@action=redirect&bpo=26664]: Fix `activate.fish` by removing mis-use of `$`.
- [bpo-22115](https://bugs.python.org/issue?@action=redirect&bpo=22115) [https://bugs.python.org/issue?@action=redirect&bpo=22115]: Fixed tracing Tkinter variables: `trace_vdelete()` with wrong mode no longer break tracing, `trace_vinfo()` now always returns a list of pairs of strings, tracing in the “u” mode now works.
- Fix a scoping issue in `importlib.util.LazyLoader` which triggered an `UnboundLocalError` when lazy-loading a module that was already put into `sys.modules`.
- [bpo-27079](https://bugs.python.org/issue?@action=redirect&bpo=27079) [https://bugs.python.org/issue?@action=redirect&bpo=27079]: Fixed `curses.ascii` functions `isblank()`, `isctrl()` and `ispunct()`.

- [bpo-26754](https://bugs.python.org/issue?@action=redirect&bpo=26754) [https://bugs.python.org/issue?@action=redirect&bpo=26754]: Some functions (compile() etc) accepted a filename argument encoded as an iterable of integers. Now only strings and byte-like objects are accepted.
- [bpo-27048](https://bugs.python.org/issue?@action=redirect&bpo=27048) [https://bugs.python.org/issue?@action=redirect&bpo=27048]: Prevents distutils failing on Windows when environment variables contain non-ASCII characters
- [bpo-27330](https://bugs.python.org/issue?@action=redirect&bpo=27330) [https://bugs.python.org/issue?@action=redirect&bpo=27330]: Fixed possible leaks in the ctypes module.
- [bpo-27238](https://bugs.python.org/issue?@action=redirect&bpo=27238) [https://bugs.python.org/issue?@action=redirect&bpo=27238]: Got rid of bare excepts in the turtle module. Original patch by Jelle Zijlstra.
- [bpo-27122](https://bugs.python.org/issue?@action=redirect&bpo=27122) [https://bugs.python.org/issue?@action=redirect&bpo=27122]: When an exception is raised within the context being managed by a contextlib.ExitStack() and one of the exit stack generators catches and raises it in a chain, do not re-raise the original exception when exiting, let the new chained one through. This avoids the [PEP 479](#) [https://peps.python.org/pep-0479/] bug described in issue25782.
- [bpo-26386](https://bugs.python.org/issue?@action=redirect&bpo=26386) [https://bugs.python.org/issue?@action=redirect&bpo=26386]: Fixed ttk.TreeView selection operations with item id's containing spaces.
- [bpo-16182](https://bugs.python.org/issue?@action=redirect&bpo=16182) [https://bugs.python.org/issue?@action=redirect&bpo=16182]: Fix various functions in the "readline" module to use the locale encoding, and fix get\_begidx() and get\_endidx() to return code point indexes.
- [bpo-27392](https://bugs.python.org/issue?@action=redirect&bpo=27392) [https://bugs.python.org/issue?@action=redirect&bpo=27392]: Add loop.connect\_accepted\_socket(). Patch by Jim Fulton.
- [bpo-27930](https://bugs.python.org/issue?@action=redirect&bpo=27930) [https://bugs.python.org/issue?@action=redirect&bpo=27930]: Improved behaviour of logging.handlers.QueueListener. Thanks to Paulo Andrade and Petr Viktorin for the analysis and patch.
- [bpo-21201](https://bugs.python.org/issue?@action=redirect&bpo=21201) [https://bugs.python.org/issue?@action=redirect&bpo=21201]: Improves readability of multiprocessing error message. Thanks to Wojciech Walczak for patch.
- [bpo-27456](https://bugs.python.org/issue?@action=redirect&bpo=27456) [https://bugs.python.org/issue?@action=redirect&bpo=27456]

@action=redirect&bpo=27456]: `asyncio`: Set `TCP_NODELAY` by default.

- [bpo-27906](https://bugs.python.org/issue?@action=redirect&bpo=27906) [https://bugs.python.org/issue?@action=redirect&bpo=27906]: Fix socket accept exhaustion during high TCP traffic. Patch by Kevin Conway.
- [bpo-28174](https://bugs.python.org/issue?@action=redirect&bpo=28174) [https://bugs.python.org/issue?@action=redirect&bpo=28174]: Handle when `SO_REUSEPORT` isn't properly supported. Patch by Seth Michael Larson.
- [bpo-26654](https://bugs.python.org/issue?@action=redirect&bpo=26654) [https://bugs.python.org/issue?@action=redirect&bpo=26654]: Inspect `functools.partial` in `asyncio.Handle._repr_`. Patch by iceboy.
- [bpo-26909](https://bugs.python.org/issue?@action=redirect&bpo=26909) [https://bugs.python.org/issue?@action=redirect&bpo=26909]: Fix slow pipes IO in `asyncio`. Patch by INADA Naoki.
- [bpo-28176](https://bugs.python.org/issue?@action=redirect&bpo=28176) [https://bugs.python.org/issue?@action=redirect&bpo=28176]: Fix callbacks race in `asyncio.SelectorLoop.sock_connect`.
- [bpo-27759](https://bugs.python.org/issue?@action=redirect&bpo=27759) [https://bugs.python.org/issue?@action=redirect&bpo=27759]: Fix selectors incorrectly retain invalid file descriptors. Patch by Mark Williams.
- [bpo-28368](https://bugs.python.org/issue?@action=redirect&bpo=28368) [https://bugs.python.org/issue?@action=redirect&bpo=28368]: Refuse monitoring processes if the child watcher has no loop attached. Patch by Vincent Michel.
- [bpo-28369](https://bugs.python.org/issue?@action=redirect&bpo=28369) [https://bugs.python.org/issue?@action=redirect&bpo=28369]: Raise `RuntimeError` when transport's FD is used with `add_reader`, `add_writer`, etc.
- [bpo-28370](https://bugs.python.org/issue?@action=redirect&bpo=28370) [https://bugs.python.org/issue?@action=redirect&bpo=28370]: Speedup `asyncio.StreamReader.readexactly`. Patch by Коренберг Марк.
- [bpo-28371](https://bugs.python.org/issue?@action=redirect&bpo=28371) [https://bugs.python.org/issue?@action=redirect&bpo=28371]: Deprecate passing `asyncio.Handles` to `run_in_executor`.
- [bpo-28372](https://bugs.python.org/issue?@action=redirect&bpo=28372) [https://bugs.python.org/issue?@action=redirect&bpo=28372]: Fix `asyncio` to support formatting of non-python coroutines.
- [bpo-28399](https://bugs.python.org/issue?@action=redirect&bpo=28399) [https://bugs.python.org/issue?@action=redirect&bpo=28399]: Remove UNIX socket from FS before binding. Patch by Коренберг Марк.
- [bpo-27972](https://bugs.python.org/issue?@action=redirect&bpo=27972) [https://bugs.python.org/issue?@action=redirect&bpo=27972]

@action=redirect&bpo=27972]: Prohibit Tasks to await on themselves.

- [bpo-26923](https://bugs.python.org/issue?@action=redirect&bpo=26923) [https://bugs.python.org/issue?@action=redirect&bpo=26923]: Fix asyncio.Gather to refuse being cancelled once all children are done. Patch by Johannes Ebke.
- [bpo-26796](https://bugs.python.org/issue?@action=redirect&bpo=26796) [https://bugs.python.org/issue?@action=redirect&bpo=26796]: Don't configure the number of workers for default threadpool executor. Initial patch by Hans Lawrenz.
- [bpo-28600](https://bugs.python.org/issue?@action=redirect&bpo=28600) [https://bugs.python.org/issue?@action=redirect&bpo=28600]: Optimize loop.call\_soon().
- [bpo-28613](https://bugs.python.org/issue?@action=redirect&bpo=28613) [https://bugs.python.org/issue?@action=redirect&bpo=28613]: Fix get\_event\_loop() return the current loop if called from coroutines/callbacks.
- [bpo-28639](https://bugs.python.org/issue?@action=redirect&bpo=28639) [https://bugs.python.org/issue?@action=redirect&bpo=28639]: Fix inspect.isawaitable to always return bool Patch by Justin Mayfield.
- [bpo-28652](https://bugs.python.org/issue?@action=redirect&bpo=28652) [https://bugs.python.org/issue?@action=redirect&bpo=28652]: Make loop methods reject socket kinds they do not support.
- [bpo-28653](https://bugs.python.org/issue?@action=redirect&bpo=28653) [https://bugs.python.org/issue?@action=redirect&bpo=28653]: Fix a reflink in functools.lru\_cache.
- [bpo-28703](https://bugs.python.org/issue?@action=redirect&bpo=28703) [https://bugs.python.org/issue?@action=redirect&bpo=28703]: Fix asyncio.iscoroutinefunction to handle Mock objects.
- [bpo-24142](https://bugs.python.org/issue?@action=redirect&bpo=24142) [https://bugs.python.org/issue?@action=redirect&bpo=24142]: Reading a corrupt config file left the parser in an invalid state. Original patch by Florian Höch.
- [bpo-28990](https://bugs.python.org/issue?@action=redirect&bpo=28990) [https://bugs.python.org/issue?@action=redirect&bpo=28990]: Fix SSL hanging if connection is closed before handshake completed. (Patch by HoHo-Ho)

## IDLE

- [bpo-15308](https://bugs.python.org/issue?@action=redirect&bpo=15308) [https://bugs.python.org/issue?@action=redirect&bpo=15308]: Add 'interrupt execution' (^C) to Shell menu. Patch by Roger Serwy, updated by Bayard Randel.
- [bpo-27922](https://bugs.python.org/issue?@action=redirect&bpo=27922) [https://bugs.python.org/issue?@action=redirect&bpo=27922]

@action=redirect&bpo=27922]: Stop IDLE tests from ‘flashing’ gui widgets on the screen.

- Add version to title of IDLE help window.
- [bpo-25564](https://bugs.python.org/issue?@action=redirect&bpo=25564) [https://bugs.python.org/issue?@action=redirect&bpo=25564]: In section on IDLE – console differences, mention that using exec means that `_builtins_` is defined for each statement.
- [bpo-27714](https://bugs.python.org/issue?@action=redirect&bpo=27714) [https://bugs.python.org/issue?@action=redirect&bpo=27714]: `test_textview` and `test_autocomplete` now pass when re-run in the same process. This occurs when `test_idle` fails when run with the `-w` option but without `-jn`. Fix warning from `test_config`.
- [bpo-25507](https://bugs.python.org/issue?@action=redirect&bpo=25507) [https://bugs.python.org/issue?@action=redirect&bpo=25507]: IDLE no longer runs buggy code because of its tkinter imports. Users must include the same imports required to run directly in Python.
- [bpo-27452](https://bugs.python.org/issue?@action=redirect&bpo=27452) [https://bugs.python.org/issue?@action=redirect&bpo=27452]: add line counter and crc to IDLE `configHandler` test dump.
- [bpo-27365](https://bugs.python.org/issue?@action=redirect&bpo=27365) [https://bugs.python.org/issue?@action=redirect&bpo=27365]: Allow non-ascii chars in IDLE `NEWS.txt`, for contributor names.
- [bpo-27245](https://bugs.python.org/issue?@action=redirect&bpo=27245) [https://bugs.python.org/issue?@action=redirect&bpo=27245]: IDLE: Cleanly delete custom themes and key bindings. Previously, when IDLE was started from a console or by import, a cascade of warnings was emitted. Patch by Serhiy Storchaka.

## C API

- [bpo-28808](https://bugs.python.org/issue?@action=redirect&bpo=28808) [https://bugs.python.org/issue?@action=redirect&bpo=28808]: `PyUnicode_CompareWithASCIIString()` now never raises exceptions.
- [bpo-26754](https://bugs.python.org/issue?@action=redirect&bpo=26754) [https://bugs.python.org/issue?@action=redirect&bpo=26754]: `PyUnicode_FSDecoder()` accepted a filename argument encoded as an iterable of integers. Now only strings and bytes-like objects are accepted.

## Documentation

- [bpo-28513](https://bugs.python.org/issue?@action=redirect&bpo=28513) [https://bugs.python.org/issue?@action=redirect&bpo=28513]: Documented command-line interface of zipfile.

## Tests

- [bpo-28950](https://bugs.python.org/issue?@action=redirect&bpo=28950) [https://bugs.python.org/issue?@action=redirect&bpo=28950]: Disallow -j0 to be combined with -T/-l/-M in regrtest command line arguments.
- [bpo-28666](https://bugs.python.org/issue?@action=redirect&bpo=28666) [https://bugs.python.org/issue?@action=redirect&bpo=28666]: Now test.support.rmtree is able to remove unwritable or unreadable directories.
- [bpo-23839](https://bugs.python.org/issue?@action=redirect&bpo=23839) [https://bugs.python.org/issue?@action=redirect&bpo=23839]: Various caches now are cleared before running every test file.
- [bpo-28409](https://bugs.python.org/issue?@action=redirect&bpo=28409) [https://bugs.python.org/issue?@action=redirect&bpo=28409]: regrtest: fix the parser of command line arguments.
- [bpo-27787](https://bugs.python.org/issue?@action=redirect&bpo=27787) [https://bugs.python.org/issue?@action=redirect&bpo=27787]: Call gc.collect() before checking each test for “dangling threads”, since the dangling threads are weak references.
- [bpo-27369](https://bugs.python.org/issue?@action=redirect&bpo=27369) [https://bugs.python.org/issue?@action=redirect&bpo=27369]: In test\_pyexpat, avoid testing an error message detail that changed in Expat 2.2.0.

## Tools/Demos

- [bpo-27952](https://bugs.python.org/issue?@action=redirect&bpo=27952) [https://bugs.python.org/issue?@action=redirect&bpo=27952]: Get Tools/scripts/fixcid.py working with Python 3 and the current “re” module, avoid invalid Python backslash escapes, and fix a bug parsing escaped C quote signs.
- [bpo-27332](https://bugs.python.org/issue?@action=redirect&bpo=27332) [https://bugs.python.org/issue?@action=redirect&bpo=27332]: Fixed the type of the first argument of module-level functions generated by Argument Clinic. Patch by Petr Viktorin.
- [bpo-27418](https://bugs.python.org/issue?@action=redirect&bpo=27418) [https://bugs.python.org/issue?@action=redirect&bpo=27418]: Fixed Tools/importbench/importbench.py.

## Windows

- [bpo-28251](https://bugs.python.org/issue?@action=redirect&bpo=28251) [https://bugs.python.org/issue?@action=redirect&bpo=28251]: Improvements to help manuals on Windows.
- [bpo-28110](https://bugs.python.org/issue?@action=redirect&bpo=28110) [https://bugs.python.org/issue?@action=redirect&bpo=28110]: launcher.msi has different product codes between 32-bit and 64-bit
- [bpo-25144](https://bugs.python.org/issue?@action=redirect&bpo=25144) [https://bugs.python.org/issue?@action=redirect&bpo=25144]: Ensures TargetDir is set before continuing with custom install.
- [bpo-27469](https://bugs.python.org/issue?@action=redirect&bpo=27469) [https://bugs.python.org/issue?@action=redirect&bpo=27469]: Adds a shell extension to the launcher so that drag and drop works correctly.
- [bpo-27309](https://bugs.python.org/issue?@action=redirect&bpo=27309) [https://bugs.python.org/issue?@action=redirect&bpo=27309]: Enabled proper Windows styles in python[w].exe manifest.

## Build

- [bpo-29080](https://bugs.python.org/issue?@action=redirect&bpo=29080) [https://bugs.python.org/issue?@action=redirect&bpo=29080]: Removes hard dependency on hg.exe from PCBuild/build.bat
- [bpo-23903](https://bugs.python.org/issue?@action=redirect&bpo=23903) [https://bugs.python.org/issue?@action=redirect&bpo=23903]: Added missed names to PC/python3.def.
- [bpo-10656](https://bugs.python.org/issue?@action=redirect&bpo=10656) [https://bugs.python.org/issue?@action=redirect&bpo=10656]: Fix out-of-tree building on AIX. Patch by Tristan Carel and Michael Haubenwallner.
- [bpo-26359](https://bugs.python.org/issue?@action=redirect&bpo=26359) [https://bugs.python.org/issue?@action=redirect&bpo=26359]: Rename `-with-optimizations` to `-enable-optimizations`.
- [bpo-28444](https://bugs.python.org/issue?@action=redirect&bpo=28444) [https://bugs.python.org/issue?@action=redirect&bpo=28444]: Fix missing extensions modules when cross compiling.
- [bpo-28248](https://bugs.python.org/issue?@action=redirect&bpo=28248) [https://bugs.python.org/issue?@action=redirect&bpo=28248]: Update Windows build and OS X installers to use OpenSSL 1.0.2j.
- [bpo-28258](https://bugs.python.org/issue?@action=redirect&bpo=28258) [https://bugs.python.org/issue?@action=redirect&bpo=28258]: Fixed build with Estonian locale

(python-config and distclean targets in Makefile). Patch by Arfrever Frehtes Taifersar Arahesis.

- [bpo-26661](https://bugs.python.org/issue?@action=redirect&bpo=26661) [https://bugs.python.org/issue?@action=redirect&bpo=26661]: setup.py now detects system libffi with multiarch wrapper.
- [bpo-28066](https://bugs.python.org/issue?@action=redirect&bpo=28066) [https://bugs.python.org/issue?@action=redirect&bpo=28066]: Fix the logic that searches build directories for generated include files when building outside the source tree.
- [bpo-15819](https://bugs.python.org/issue?@action=redirect&bpo=15819) [https://bugs.python.org/issue?@action=redirect&bpo=15819]: Remove redundant include search directory option for building outside the source tree.
- [bpo-27566](https://bugs.python.org/issue?@action=redirect&bpo=27566) [https://bugs.python.org/issue?@action=redirect&bpo=27566]: Fix clean target in freeze makefile (patch by Lisa Roach)
- [bpo-27705](https://bugs.python.org/issue?@action=redirect&bpo=27705) [https://bugs.python.org/issue?@action=redirect&bpo=27705]: Update message in validate\_ucrtbase.py
- [bpo-27983](https://bugs.python.org/issue?@action=redirect&bpo=27983) [https://bugs.python.org/issue?@action=redirect&bpo=27983]: Cause lack of llvm-profdata tool when using clang as required for PGO linking to be a configure time error rather than make time when `-with-optimizations` is enabled. Also improve our ability to find the llvm-profdata tool on MacOS and some Linuxes.
- [bpo-26307](https://bugs.python.org/issue?@action=redirect&bpo=26307) [https://bugs.python.org/issue?@action=redirect&bpo=26307]: The profile-opt build now applies PGO to the built-in modules.
- [bpo-26359](https://bugs.python.org/issue?@action=redirect&bpo=26359) [https://bugs.python.org/issue?@action=redirect&bpo=26359]: Add the `-with-optimizations` configure flag.
- [bpo-27713](https://bugs.python.org/issue?@action=redirect&bpo=27713) [https://bugs.python.org/issue?@action=redirect&bpo=27713]: Suppress spurious build warnings when updating importlib's bootstrap files. Patch by Xiang Zhang
- [bpo-25825](https://bugs.python.org/issue?@action=redirect&bpo=25825) [https://bugs.python.org/issue?@action=redirect&bpo=25825]: Correct the references to Modules/python.exp and ld\_so\_aix, which are required on AIX. This updates references to an installation path that was changed in 3.2a4, and undoes changed references to the build tree that were made in 3.5.0a1.

- [bpo-27453](https://bugs.python.org/issue?@action=redirect&bpo=27453) [https://bugs.python.org/issue?@action=redirect&bpo=27453]: CPP invocation in configure must use CPPFLAGS. Patch by Chi Hsuan Yen.
- [bpo-27641](https://bugs.python.org/issue?@action=redirect&bpo=27641) [https://bugs.python.org/issue?@action=redirect&bpo=27641]: The configure script now inserts comments into the makefile to prevent the pgen and \_freeze\_importlib executables from being cross-compiled.
- [bpo-26662](https://bugs.python.org/issue?@action=redirect&bpo=26662) [https://bugs.python.org/issue?@action=redirect&bpo=26662]: Set PYTHON\_FOR\_GEN in configure as the Python program to be used for file generation during the build.
- [bpo-10910](https://bugs.python.org/issue?@action=redirect&bpo=10910) [https://bugs.python.org/issue?@action=redirect&bpo=10910]: Avoid C + + compilation errors on FreeBSD and OS X. Also update FreeBSD version checks for the original ctype UTF-8 workaround.
- [bpo-28676](https://bugs.python.org/issue?@action=redirect&bpo=28676) [https://bugs.python.org/issue?@action=redirect&bpo=28676]: Prevent missing ‘getentropy’ declaration warning on macOS. Patch by Gareth Rees.

## Python 3.5.2 final

*Release date: 2016-06-26*

### Core and Builtins

- [bpo-26930](https://bugs.python.org/issue?@action=redirect&bpo=26930) [https://bugs.python.org/issue?@action=redirect&bpo=26930]: Update Windows builds to use OpenSSL 1.0.2h.

### Tests

- [bpo-26867](https://bugs.python.org/issue?@action=redirect&bpo=26867) [https://bugs.python.org/issue?@action=redirect&bpo=26867]: Ubuntu’s openssl OP\_NO\_SSLv3 is forced on by default; fix test.

### IDLE

- [bpo-27365](https://bugs.python.org/issue?@action=redirect&bpo=27365) [https://bugs.python.org/issue?@action=redirect&bpo=27365]: Allow non-ascii in idlelib/

# Python 3.5.2 release candidate 1

*Release date: 2016-06-12*

## Security

- [bpo-26556](https://bugs.python.org/issue?@action=redirect&bpo=26556) [https://bugs.python.org/issue?@action=redirect&bpo=26556]: Update expat to 2.1.1, fixes CVE-2015-1283.
- Fix TLS stripping vulnerability in smtplib, CVE-2016-0772. Reported by Team Oststrom
- [bpo-26839](https://bugs.python.org/issue?@action=redirect&bpo=26839) [https://bugs.python.org/issue?@action=redirect&bpo=26839]: On Linux, `os.urandom()` now calls `getrandom()` with `GRND_NONBLOCK` to fall back on reading `/dev/urandom` if the urandom entropy pool is not initialized yet. Patch written by Colm Buckley.
- [bpo-26657](https://bugs.python.org/issue?@action=redirect&bpo=26657) [https://bugs.python.org/issue?@action=redirect&bpo=26657]: Fix directory traversal vulnerability with `http.server` on Windows. This fixes a regression that was introduced in 3.3.4rc1 and 3.4.0rc1. Based on patch by Philipp Hagemeister.
- [bpo-26313](https://bugs.python.org/issue?@action=redirect&bpo=26313) [https://bugs.python.org/issue?@action=redirect&bpo=26313]: `ssl.py_load_windows_store_certs` fails if windows cert store is empty. Patch by Baji.
- [bpo-25939](https://bugs.python.org/issue?@action=redirect&bpo=25939) [https://bugs.python.org/issue?@action=redirect&bpo=25939]: On Windows open the cert store readonly in `ssl.enum_certificates`.

## Core and Builtins

- [bpo-27066](https://bugs.python.org/issue?@action=redirect&bpo=27066) [https://bugs.python.org/issue?@action=redirect&bpo=27066]: Fixed `SystemError` if a custom opener (for `open()`) returns a negative number without setting an exception.
- [bpo-20041](https://bugs.python.org/issue?@action=redirect&bpo=20041) [https://bugs.python.org/issue?@action=redirect&bpo=20041]: Fixed `TypeError` when `frame.f_trace` is set to `None`. Patch by Xavier de Gaye.

- [bpo-26168](https://bugs.python.org/issue?@action=redirect&bpo=26168) [https://bugs.python.org/issue?@action=redirect&bpo=26168]: Fixed possible refleaks in failing `Py_BuildValue()` with the “N” format unit.
- [bpo-26991](https://bugs.python.org/issue?@action=redirect&bpo=26991) [https://bugs.python.org/issue?@action=redirect&bpo=26991]: Fix possible refleak when creating a function with annotations.
- [bpo-27039](https://bugs.python.org/issue?@action=redirect&bpo=27039) [https://bugs.python.org/issue?@action=redirect&bpo=27039]: Fixed `bytearray.remove()` for values greater than 127. Patch by Joe Jevnik.
- [bpo-23640](https://bugs.python.org/issue?@action=redirect&bpo=23640) [https://bugs.python.org/issue?@action=redirect&bpo=23640]: `int.from_bytes()` no longer bypasses constructors for subclasses.
- [bpo-26811](https://bugs.python.org/issue?@action=redirect&bpo=26811) [https://bugs.python.org/issue?@action=redirect&bpo=26811]: `gc.get_objects()` no longer contains a broken tuple with NULL pointer.
- [bpo-20120](https://bugs.python.org/issue?@action=redirect&bpo=20120) [https://bugs.python.org/issue?@action=redirect&bpo=20120]: Use `RawConfigParser` for `.pypirc` parsing, removing support for interpolation unintentionally added with move to Python 3. Behavior no longer does any interpolation in `.pypirc` files, matching behavior in Python 2.7 and `Setuptools` 19.0.
- [bpo-26659](https://bugs.python.org/issue?@action=redirect&bpo=26659) [https://bugs.python.org/issue?@action=redirect&bpo=26659]: Make the builtin slice type support cycle collection.
- [bpo-26718](https://bugs.python.org/issue?@action=redirect&bpo=26718) [https://bugs.python.org/issue?@action=redirect&bpo=26718]: `super.__init__` no longer leaks memory if called multiple times. NOTE: A direct call of `super.__init__` is not endorsed!
- [bpo-25339](https://bugs.python.org/issue?@action=redirect&bpo=25339) [https://bugs.python.org/issue?@action=redirect&bpo=25339]: `PYTHONIOENCODING` now has priority over locale in setting the error handler for stdin and stdout.
- [bpo-26494](https://bugs.python.org/issue?@action=redirect&bpo=26494) [https://bugs.python.org/issue?@action=redirect&bpo=26494]: Fixed crash on iterating exhausting iterators. Affected classes are generic sequence iterators, iterators of str, bytes, bytearray, list, tuple, set, frozenset, dict, `OrderedDict`, corresponding views and `os.scandir()` iterator.
- [bpo-26581](https://bugs.python.org/issue?@action=redirect&bpo=26581) [https://bugs.python.org/issue?@action=redirect&bpo=26581]: If coding cookie is specified

multiple times on a line in Python source code file, only the first one is taken to account.

- [bpo-26464](https://bugs.python.org/issue?@action=redirect&bpo=26464) [https://bugs.python.org/issue?@action=redirect&bpo=26464]: Fix str.translate() when string is ASCII and first replacements removes character, but next replacement uses a non-ASCII character or a string longer than 1 character. Regression introduced in Python 3.5.0.
- [bpo-22836](https://bugs.python.org/issue?@action=redirect&bpo=22836) [https://bugs.python.org/issue?@action=redirect&bpo=22836]: Ensure exception reports from PyErr\_Display() and PyErr\_WriteUnraisable() are sensible even when formatting them produces secondary errors. This affects the reports produced by sys.\_excepthook\_() and when \_del\_() raises an exception.
- [bpo-26302](https://bugs.python.org/issue?@action=redirect&bpo=26302) [https://bugs.python.org/issue?@action=redirect&bpo=26302]: Correct behavior to reject comma as a legal character for cookie names.
- [bpo-4806](https://bugs.python.org/issue?@action=redirect&bpo=4806) [https://bugs.python.org/issue?@action=redirect&bpo=4806]: Avoid masking the original TypeError exception when using star (\*) unpacking in function calls. Based on patch by Hagen Fürstenau and Daniel Urban.
- [bpo-27138](https://bugs.python.org/issue?@action=redirect&bpo=27138) [https://bugs.python.org/issue?@action=redirect&bpo=27138]: Fix the doc comment for FileFinder.find\_spec().
- [bpo-26154](https://bugs.python.org/issue?@action=redirect&bpo=26154) [https://bugs.python.org/issue?@action=redirect&bpo=26154]: Add a new private \_PyThreadState\_UncheckedGet() function to get the current Python thread state, but don't issue a fatal error if it is NULL. This new function must be used instead of accessing directly the \_PyThreadState\_Current variable. The variable is no more exposed since Python 3.5.1 to hide the exact implementation of atomic C types, to avoid compiler issues.
- [bpo-26194](https://bugs.python.org/issue?@action=redirect&bpo=26194) [https://bugs.python.org/issue?@action=redirect&bpo=26194]: Deque.insert() gave odd results for bounded deques that had reached their maximum size. Now an IndexError will be raised when attempting to insert into a full deque.
- [bpo-25843](https://bugs.python.org/issue?@action=redirect&bpo=25843) [https://bugs.python.org/issue?@action=redirect&bpo=25843]: When compiling code, don't merge constants if they are equal but have a different types. For example, f1, f2 = lambda: 1, lambda: 1.0 is

now correctly compiled to two different functions: `f1()` returns `1 (int)` and `f2()` returns `1.0 (int)`, even if `1` and `1.0` are equal.

- [bpo-22995](https://bugs.python.org/issue?@action=redirect&bpo=22995) [https://bugs.python.org/issue?@action=redirect&bpo=22995]: [UPDATE] Comment out the one of the pickleability tests in `_PyObject_GetState()` due to regressions observed in Cython-based projects.
- [bpo-25961](https://bugs.python.org/issue?@action=redirect&bpo=25961) [https://bugs.python.org/issue?@action=redirect&bpo=25961]: Disallowed null characters in the type name.
- [bpo-25973](https://bugs.python.org/issue?@action=redirect&bpo=25973) [https://bugs.python.org/issue?@action=redirect&bpo=25973]: Fix segfault when an invalid nonlocal statement binds a name starting with two underscores.
- [bpo-22995](https://bugs.python.org/issue?@action=redirect&bpo=22995) [https://bugs.python.org/issue?@action=redirect&bpo=22995]: Instances of extension types with a state that aren't subclasses of list or dict and haven't implemented any pickle-related methods (`__reduce__`, `__reduce_ex__`, `__getnewargs__`, `__getnewargs_ex__`, or `__getstate__`), can no longer be pickled. Including memoryview.
- [bpo-20440](https://bugs.python.org/issue?@action=redirect&bpo=20440) [https://bugs.python.org/issue?@action=redirect&bpo=20440]: Massive replacing unsafe attribute setting code with special macro `Py_SETREF`.
- [bpo-25766](https://bugs.python.org/issue?@action=redirect&bpo=25766) [https://bugs.python.org/issue?@action=redirect&bpo=25766]: Special method `__bytes__()` now works in str subclasses.
- [bpo-25421](https://bugs.python.org/issue?@action=redirect&bpo=25421) [https://bugs.python.org/issue?@action=redirect&bpo=25421]: `__sizeof__` methods of builtin types now use dynamic basic size. This allows `sys.getsize()` to work correctly with their subclasses with `__slots__` defined.
- [bpo-25709](https://bugs.python.org/issue?@action=redirect&bpo=25709) [https://bugs.python.org/issue?@action=redirect&bpo=25709]: Fixed problem with in-place string concatenation and utf-8 cache.
- [bpo-27147](https://bugs.python.org/issue?@action=redirect&bpo=27147) [https://bugs.python.org/issue?@action=redirect&bpo=27147]: Mention **PEP 420** [https://peps.python.org/pep-0420/] in the `importlib` docs.
- [bpo-24097](https://bugs.python.org/issue?@action=redirect&bpo=24097) [https://bugs.python.org/issue?@action=redirect&bpo=24097]: Fixed crash in `object.__reduce__()` if slot name is freed inside `__getattr__`.

- [bpo-24731](https://bugs.python.org/issue?@action=redirect&bpo=24731) [https://bugs.python.org/issue?@action=redirect&bpo=24731]: Fixed crash on converting objects with special methods `__bytes__`, `__trunc__`, and `__float__` returning instances of subclasses of bytes, int, and float to subclasses of bytes, int, and float correspondingly.
- [bpo-26478](https://bugs.python.org/issue?@action=redirect&bpo=26478) [https://bugs.python.org/issue?@action=redirect&bpo=26478]: Fix semantic bugs when using binary operators with dictionary views and tuples.
- [bpo-26171](https://bugs.python.org/issue?@action=redirect&bpo=26171) [https://bugs.python.org/issue?@action=redirect&bpo=26171]: Fix possible integer overflow and heap corruption in `zipimporter.get_data()`.
- [bpo-25660](https://bugs.python.org/issue?@action=redirect&bpo=25660) [https://bugs.python.org/issue?@action=redirect&bpo=25660]: Fix TAB key behaviour in REPL with readline.
- [bpo-25887](https://bugs.python.org/issue?@action=redirect&bpo=25887) [https://bugs.python.org/issue?@action=redirect&bpo=25887]: Raise a `RuntimeError` when a coroutine object is awaited more than once.
- [bpo-27243](https://bugs.python.org/issue?@action=redirect&bpo=27243) [https://bugs.python.org/issue?@action=redirect&bpo=27243]: Update the `__aiter__` protocol: instead of returning an awaitable that resolves to an asynchronous iterator, the asynchronous iterator should be returned directly. Doing the former will trigger a `PendingDeprecationWarning`.

## Library

- [bpo-21386](https://bugs.python.org/issue?@action=redirect&bpo=21386) [https://bugs.python.org/issue?@action=redirect&bpo=21386]: Implement missing `IPv4Address.is_global` property. It was documented since 07a5610bae9d. Initial patch by Roger Luethi.
- [bpo-20900](https://bugs.python.org/issue?@action=redirect&bpo=20900) [https://bugs.python.org/issue?@action=redirect&bpo=20900]: `distutils` register command now decodes HTTP responses correctly. Initial patch by ingrid.
- A new version of `typing.py` provides several new classes and features: `@overload` outside stubs, `Reversible`, `DefaultDict`, `Text`, `ContextManager`, `Type[]`, `NewType()`, `TYPE_CHECKING`, and numerous bug fixes (note that some of the new features are not yet implemented in `mypy` or other static analyzers). Also classes for [PEP 492](https://peps.python.org/pep-0492/) [https://peps.python.org/pep-0492/] (`Awaitable`, `AsyncIterable`, `AsyncIterator`) have been added

(in fact they made it into 3.5.1 but were never mentioned).

- [bpo-25738](https://bugs.python.org/issue?@action=redirect&bpo=25738) [https://bugs.python.org/issue?@action=redirect&bpo=25738]: Stop `http.server.BaseHTTPRequestHandler.send_error()` from sending a message body for 205 Reset Content. Also, don't send Content header fields in responses that don't have a body. Patch by Susumu Koshihara.
- [bpo-21313](https://bugs.python.org/issue?@action=redirect&bpo=21313) [https://bugs.python.org/issue?@action=redirect&bpo=21313]: Fix the “platform” module to tolerate when `sys.version` contains truncated build information.
- [bpo-27164](https://bugs.python.org/issue?@action=redirect&bpo=27164) [https://bugs.python.org/issue?@action=redirect&bpo=27164]: In the `zlib` module, allow decompressing raw Deflate streams with a predefined `zdict`. Based on patch by Xiang Zhang.
- [bpo-24291](https://bugs.python.org/issue?@action=redirect&bpo=24291) [https://bugs.python.org/issue?@action=redirect&bpo=24291]: Fix `wsgiref.simple_server.WSGIRequestHandler` to completely write data to the client. Previously it could do partial writes and truncate data. Also, `wsgiref.handler.ServerHandler` can now handle `stdout` doing partial writes, but this is deprecated.
- [bpo-26809](https://bugs.python.org/issue?@action=redirect&bpo=26809) [https://bugs.python.org/issue?@action=redirect&bpo=26809]: Add `__all__` to `string`. Patch by Emanuel Barry.
- [bpo-26373](https://bugs.python.org/issue?@action=redirect&bpo=26373) [https://bugs.python.org/issue?@action=redirect&bpo=26373]: `subprocess.Popen.communicate` now correctly ignores `BrokenPipeError` when the child process dies before `.communicate()` is called in `more/all` circumstances.
- [bpo-21776](https://bugs.python.org/issue?@action=redirect&bpo=21776) [https://bugs.python.org/issue?@action=redirect&bpo=21776]: `distutils.upload` now correctly handles `HTTPError`. Initial patch by Claudiu Popa.
- [bpo-27114](https://bugs.python.org/issue?@action=redirect&bpo=27114) [https://bugs.python.org/issue?@action=redirect&bpo=27114]: Fix `SSLContext.load_windows_store_certs` fails with `PermissionError`
- [bpo-18383](https://bugs.python.org/issue?@action=redirect&bpo=18383) [https://bugs.python.org/issue?@action=redirect&bpo=18383]: Avoid creating duplicate filters when using `filterwarnings` and `simplefilter`. Based on patch by Alex Shkop.

- [bpo-27057](https://bugs.python.org/issue?@action=redirect&bpo=27057) [https://bugs.python.org/issue?@action=redirect&bpo=27057]: Fix `os.set_inheritable()` on Android, `ioctl()` is blocked by SELinux and fails with `EACCESS`. The function now falls back to `fcntl()`. Patch written by Michał Bednarski.
- [bpo-27014](https://bugs.python.org/issue?@action=redirect&bpo=27014) [https://bugs.python.org/issue?@action=redirect&bpo=27014]: Fix infinite recursion using `typing.py`. Thanks to Kalle Tuure!
- [bpo-14132](https://bugs.python.org/issue?@action=redirect&bpo=14132) [https://bugs.python.org/issue?@action=redirect&bpo=14132]: Fix `urllib.request` redirect handling when the target only has a query string. Original fix by Ján Janech.
- [bpo-17214](https://bugs.python.org/issue?@action=redirect&bpo=17214) [https://bugs.python.org/issue?@action=redirect&bpo=17214]: The “`urllib.request`” module now percent-encodes non-ASCII bytes found in redirect target URLs. Some servers send Location header fields with non-ASCII bytes, but “`http.client`” requires the request target to be ASCII-encodable, otherwise a `UnicodeEncodeError` is raised. Based on patch by Christian Heimes.
- [bpo-26892](https://bugs.python.org/issue?@action=redirect&bpo=26892) [https://bugs.python.org/issue?@action=redirect&bpo=26892]: Honor `debuglevel` flag in `urllib.request.HTTPHandler`. Patch contributed by Chi Hsuan Yen.
- [bpo-22274](https://bugs.python.org/issue?@action=redirect&bpo=22274) [https://bugs.python.org/issue?@action=redirect&bpo=22274]: In the `subprocess` module, allow `stderr` to be redirected to `stdout` even when `stdout` is not redirected. Patch by Akira Li.
- [bpo-26807](https://bugs.python.org/issue?@action=redirect&bpo=26807) [https://bugs.python.org/issue?@action=redirect&bpo=26807]: `mock_open` ‘files’ no longer error on readline at end of file. Patch from Yolanda Robla.
- [bpo-25745](https://bugs.python.org/issue?@action=redirect&bpo=25745) [https://bugs.python.org/issue?@action=redirect&bpo=25745]: Fixed leaking a `userptr` in `curses` panel destructor.
- [bpo-26977](https://bugs.python.org/issue?@action=redirect&bpo=26977) [https://bugs.python.org/issue?@action=redirect&bpo=26977]: Removed unnecessary, and ignored, call to `sum of squares helper` in `statistics.pvariance`.
- [bpo-26881](https://bugs.python.org/issue?@action=redirect&bpo=26881) [https://bugs.python.org/issue?@action=redirect&bpo=26881]: The `modulefinder` module now supports extended opcode arguments.
- [bpo-23815](https://bugs.python.org/issue?@action=redirect&bpo=23815) [https://bugs.python.org/issue?@action=redirect&bpo=23815]

@action=redirect&bpo=23815]: Fixed crashes related to directly created instances of types in `_tkinter` and `curses.panel` modules.

- [bpo-17765](https://bugs.python.org/issue?@action=redirect&bpo=17765) [https://bugs.python.org/issue?@action=redirect&bpo=17765]: `weakref.ref()` no longer silently ignores keyword arguments. Patch by Georg Brandl.
- [bpo-26873](https://bugs.python.org/issue?@action=redirect&bpo=26873) [https://bugs.python.org/issue?@action=redirect&bpo=26873]: `xmlrpc` now raises `ResponseError` on unsupported type tags instead of silently return incorrect result.
- [bpo-26711](https://bugs.python.org/issue?@action=redirect&bpo=26711) [https://bugs.python.org/issue?@action=redirect&bpo=26711]: Fixed the comparison of `plistlib.Data` with other types.
- [bpo-24114](https://bugs.python.org/issue?@action=redirect&bpo=24114) [https://bugs.python.org/issue?@action=redirect&bpo=24114]: Fix an uninitialized variable in `ctypes.util`. The bug only occurs on SunOS when the `ctypes` implementation searches for the `crle` program. Patch by Xiang Zhang. Tested on SunOS by Kees Bos.
- [bpo-26864](https://bugs.python.org/issue?@action=redirect&bpo=26864) [https://bugs.python.org/issue?@action=redirect&bpo=26864]: In `urllib.request`, change the proxy bypass host checking against `no_proxy` to be case-insensitive, and to not match unrelated host names that happen to have a bypassed hostname as a suffix. Patch by Xiang Zhang.
- [bpo-26634](https://bugs.python.org/issue?@action=redirect&bpo=26634) [https://bugs.python.org/issue?@action=redirect&bpo=26634]: `recursive_repr()` now sets `_qualname_` of wrapper. Patch by Xiang Zhang.
- [bpo-26804](https://bugs.python.org/issue?@action=redirect&bpo=26804) [https://bugs.python.org/issue?@action=redirect&bpo=26804]: `urllib.request` will prefer lower\_case proxy environment variables over UPPER\_CASE or Mixed\_Case ones. Patch contributed by Hans-Peter Jansen.
- [bpo-26837](https://bugs.python.org/issue?@action=redirect&bpo=26837) [https://bugs.python.org/issue?@action=redirect&bpo=26837]: `assertSequenceEqual()` now correctly outputs non-stringified differing items (like bytes in the `-b` mode). This affects `assertListEqual()` and `assertTupleEqual()`.
- [bpo-26041](https://bugs.python.org/issue?@action=redirect&bpo=26041) [https://bugs.python.org/issue?@action=redirect&bpo=26041]: Remove “will be removed in Python 3.7” from deprecation messages of `platform.dist()` and `platform.linux_distribution()`. Patch by Kumaripaba

Miyurusara Athukorala.

- [bpo-26822](https://bugs.python.org/issue?@action=redirect&bpo=26822) [https://bugs.python.org/issue?@action=redirect&bpo=26822]: itemgetter, attrgetter and methodcaller objects no longer silently ignore keyword arguments.
- [bpo-26733](https://bugs.python.org/issue?@action=redirect&bpo=26733) [https://bugs.python.org/issue?@action=redirect&bpo=26733]: Disassembling a class now disassembles class and static methods. Patch by Xiang Zhang.
- [bpo-26801](https://bugs.python.org/issue?@action=redirect&bpo=26801) [https://bugs.python.org/issue?@action=redirect&bpo=26801]: Fix error handling in `shutil.get_terminal_size()`, catch `AttributeError` instead of `NameError`. Patch written by Emanuel Barry.
- [bpo-24838](https://bugs.python.org/issue?@action=redirect&bpo=24838) [https://bugs.python.org/issue?@action=redirect&bpo=24838]: tarfile's ustar and gnu formats now correctly calculate name and link field limits for multibyte character encodings like utf-8.
- [bpo-26717](https://bugs.python.org/issue?@action=redirect&bpo=26717) [https://bugs.python.org/issue?@action=redirect&bpo=26717]: Stop encoding Latin-1-ized WSGI paths with UTF-8. Patch by Anthony Sottile.
- [bpo-26735](https://bugs.python.org/issue?@action=redirect&bpo=26735) [https://bugs.python.org/issue?@action=redirect&bpo=26735]: Fix `os.urandom()` on Solaris 11.3 and newer when reading more than 1,024 bytes: call `getrandom()` multiple times with a limit of 1024 bytes per call.
- [bpo-16329](https://bugs.python.org/issue?@action=redirect&bpo=16329) [https://bugs.python.org/issue?@action=redirect&bpo=16329]: Add `.webm` to `mimetypes.types_map`. Patch by Giampaolo Rodola'.
- [bpo-13952](https://bugs.python.org/issue?@action=redirect&bpo=13952) [https://bugs.python.org/issue?@action=redirect&bpo=13952]: Add `.csv` to `mimetypes.types_map`. Patch by Geoff Wilson.
- [bpo-26709](https://bugs.python.org/issue?@action=redirect&bpo=26709) [https://bugs.python.org/issue?@action=redirect&bpo=26709]: Fixed Y2038 problem in loading binary PLists.
- [bpo-23735](https://bugs.python.org/issue?@action=redirect&bpo=23735) [https://bugs.python.org/issue?@action=redirect&bpo=23735]: Handle terminal resizing with Readline 6.3+ by installing our own SIGWINCH handler. Patch by Eric Price.
- [bpo-26586](https://bugs.python.org/issue?@action=redirect&bpo=26586) [https://bugs.python.org/issue?@action=redirect&bpo=26586]: In `http.server`, respond with "413 Request header fields too large" if there are too many header

fields to parse, rather than killing the connection and raising an unhandled exception. Patch by Xiang Zhang.

- [bpo-22854](https://bugs.python.org/issue?@action=redirect&bpo=22854) [https://bugs.python.org/issue?@action=redirect&bpo=22854]: Change `BufferedReader.writable()` and `BufferedWriter.readable()` to always return `False`.
- [bpo-25195](https://bugs.python.org/issue?@action=redirect&bpo=25195) [https://bugs.python.org/issue?@action=redirect&bpo=25195]: Fix a regression in `mock.MagicMock._Call` is a subclass of `tuple` (`changeset 3603bae63c13` only works for classes) so we need to implement `__ne__` ourselves. Patch by Andrew Plummer.
- [bpo-26644](https://bugs.python.org/issue?@action=redirect&bpo=26644) [https://bugs.python.org/issue?@action=redirect&bpo=26644]: Raise `ValueError` rather than `SystemError` when a negative length is passed to `SSLSocket.recv()` or `read()`.
- [bpo-23804](https://bugs.python.org/issue?@action=redirect&bpo=23804) [https://bugs.python.org/issue?@action=redirect&bpo=23804]: Fix `SSL.recv(0)` and `read(0)` methods to return zero bytes instead of up to 1024.
- [bpo-26616](https://bugs.python.org/issue?@action=redirect&bpo=26616) [https://bugs.python.org/issue?@action=redirect&bpo=26616]: Fixed a bug in `datetime.astimezone()` method.
- [bpo-21925](https://bugs.python.org/issue?@action=redirect&bpo=21925) [https://bugs.python.org/issue?@action=redirect&bpo=21925]: `warnings.formatwarning()` now catches exceptions on `linecache.getline(...)` to be able to log `ResourceWarning` emitted late during the Python shutdown process.
- [bpo-24266](https://bugs.python.org/issue?@action=redirect&bpo=24266) [https://bugs.python.org/issue?@action=redirect&bpo=24266]: `Ctrl + C` during Readline history search now cancels the search mode when compiled with Readline 7.
- [bpo-26560](https://bugs.python.org/issue?@action=redirect&bpo=26560) [https://bugs.python.org/issue?@action=redirect&bpo=26560]: Avoid potential `ValueError` in `BaseHandler.start_response`. Initial patch by Peter Inglesby.
- [bpo-26569](https://bugs.python.org/issue?@action=redirect&bpo=26569) [https://bugs.python.org/issue?@action=redirect&bpo=26569]: Fix `pyclbr.readmodule()` and `pyclbr.readmodule_ex()` to support importing packages.
- [bpo-26499](https://bugs.python.org/issue?@action=redirect&bpo=26499) [https://bugs.python.org/issue?@action=redirect&bpo=26499]: Account for remaining Content-Length in `HTTPResponse.readline()` and `read1()`. Based on patch by Silent Ghost. Also document that `HTTPResponse` now supports these methods.

- [bpo-25320](https://bugs.python.org/issue?@action=redirect&bpo=25320) [https://bugs.python.org/issue?@action=redirect&bpo=25320]: Handle sockets in directories unittest discovery is scanning. Patch from Victor van den Elzen.
- [bpo-16181](https://bugs.python.org/issue?@action=redirect&bpo=16181) [https://bugs.python.org/issue?@action=redirect&bpo=16181]: cookiejar.http2time() now returns None if year is higher than datetime.MAXYEAR.
- [bpo-26513](https://bugs.python.org/issue?@action=redirect&bpo=26513) [https://bugs.python.org/issue?@action=redirect&bpo=26513]: Fixes platform module detection of Windows Server
- [bpo-23718](https://bugs.python.org/issue?@action=redirect&bpo=23718) [https://bugs.python.org/issue?@action=redirect&bpo=23718]: Fixed parsing time in week 0 before Jan 1. Original patch by Tamás Bence Gedai.
- [bpo-20589](https://bugs.python.org/issue?@action=redirect&bpo=20589) [https://bugs.python.org/issue?@action=redirect&bpo=20589]: Invoking Path.owner() and Path.group() on Windows now raise NotImplementedError instead of ImportError.
- [bpo-26177](https://bugs.python.org/issue?@action=redirect&bpo=26177) [https://bugs.python.org/issue?@action=redirect&bpo=26177]: Fixed the keys() method for Canvas and Scrollbar widgets.
- [bpo-15068](https://bugs.python.org/issue?@action=redirect&bpo=15068) [https://bugs.python.org/issue?@action=redirect&bpo=15068]: Got rid of excessive buffering in the fileinput module. The bufsize parameter is no longer used.
- [bpo-2202](https://bugs.python.org/issue?@action=redirect&bpo=2202) [https://bugs.python.org/issue?@action=redirect&bpo=2202]: Fix UnboundLocalError in AbstractDigestAuthHandler.get\_algorithm\_impls. Initial patch by Mathieu Dupuy.
- [bpo-25718](https://bugs.python.org/issue?@action=redirect&bpo=25718) [https://bugs.python.org/issue?@action=redirect&bpo=25718]: Fixed pickling and copying the accumulate() iterator with total is None.
- [bpo-26475](https://bugs.python.org/issue?@action=redirect&bpo=26475) [https://bugs.python.org/issue?@action=redirect&bpo=26475]: Fixed debugging output for regular expressions with the (?x) flag.
- [bpo-26457](https://bugs.python.org/issue?@action=redirect&bpo=26457) [https://bugs.python.org/issue?@action=redirect&bpo=26457]: Fixed the subnets() methods in IP network classes for the case when resulting prefix length is equal to maximal prefix length. Based on patch by Xiang Zhang.
- [bpo-26385](https://bugs.python.org/issue?@action=redirect&bpo=26385) [https://bugs.python.org/issue?@action=redirect&bpo=26385]: Remove the file if the internal

open() call in NamedTemporaryFile() fails. Patch by Silent Ghost.

- [bpo-26402](https://bugs.python.org/issue?@action=redirect&bpo=26402) [https://bugs.python.org/issue?@action=redirect&bpo=26402]: Fix XML-RPC client to retry when the server shuts down a persistent connection. This was a regression related to the new http.client.RemoteDisconnected exception in 3.5.0a4.
- [bpo-25913](https://bugs.python.org/issue?@action=redirect&bpo=25913) [https://bugs.python.org/issue?@action=redirect&bpo=25913]: Leading <~ is optional now in base64.a85decode() with adobe=True. Patch by Swati Jaiswal.
- [bpo-26186](https://bugs.python.org/issue?@action=redirect&bpo=26186) [https://bugs.python.org/issue?@action=redirect&bpo=26186]: Remove an invalid type check in importlib.util.LazyLoader.
- [bpo-26367](https://bugs.python.org/issue?@action=redirect&bpo=26367) [https://bugs.python.org/issue?@action=redirect&bpo=26367]: importlib.\_import\_() raises SystemError like builtins.\_import\_() when level is specified but without an accompanying package specified.
- [bpo-26309](https://bugs.python.org/issue?@action=redirect&bpo=26309) [https://bugs.python.org/issue?@action=redirect&bpo=26309]: In the “socketserver” module, shut down the request (closing the connected socket) when verify\_request() returns false. Patch by Aviv Palivoda.
- [bpo-25995](https://bugs.python.org/issue?@action=redirect&bpo=25995) [https://bugs.python.org/issue?@action=redirect&bpo=25995]: os.walk() no longer uses FDs proportional to the tree depth.
- [bpo-26117](https://bugs.python.org/issue?@action=redirect&bpo=26117) [https://bugs.python.org/issue?@action=redirect&bpo=26117]: The os.scandir() iterator now closes file descriptor not only when the iteration is finished, but when it was failed with error.
- [bpo-25911](https://bugs.python.org/issue?@action=redirect&bpo=25911) [https://bugs.python.org/issue?@action=redirect&bpo=25911]: Restored support of bytes paths in os.walk() on Windows.
- [bpo-26045](https://bugs.python.org/issue?@action=redirect&bpo=26045) [https://bugs.python.org/issue?@action=redirect&bpo=26045]: Add UTF-8 suggestion to error message when posting a non-Latin-1 string with http.client.
- [bpo-12923](https://bugs.python.org/issue?@action=redirect&bpo=12923) [https://bugs.python.org/issue?@action=redirect&bpo=12923]: Reset FancyURLopener’s redirect counter even if there is an exception. Based on patches by Brian Brazil and Daniel Rocco.
- [bpo-25945](https://bugs.python.org/issue?@action=redirect&bpo=25945) [https://bugs.python.org/issue?@action=redirect&bpo=25945]

@action=redirect&bpo=25945]: Fixed a crash when unpickle the `functools.partial` object with wrong state. Fixed a leak in failed `functools.partial` constructor. “args” and “keywords” attributes of `functools.partial` have now always types `tuple` and `dict` correspondingly.

- [bpo-26202](https://bugs.python.org/issue?@action=redirect&bpo=26202) [https://bugs.python.org/issue?@action=redirect&bpo=26202]: `copy.deepcopy()` now correctly copies `range()` objects with non-atomic attributes.
- [bpo-23076](https://bugs.python.org/issue?@action=redirect&bpo=23076) [https://bugs.python.org/issue?@action=redirect&bpo=23076]: `Path.glob()` now raises a `ValueError` if it’s called with an invalid pattern. Patch by Thomas Nyberg.
- [bpo-19883](https://bugs.python.org/issue?@action=redirect&bpo=19883) [https://bugs.python.org/issue?@action=redirect&bpo=19883]: Fixed possible integer overflows in `zipimport`.
- [bpo-26227](https://bugs.python.org/issue?@action=redirect&bpo=26227) [https://bugs.python.org/issue?@action=redirect&bpo=26227]: On Windows, `getnameinfo()`, `gethostbyaddr()` and `gethostbyname_ex()` functions of the `socket` module now decode the hostname from the ANSI code page rather than UTF-8.
- [bpo-26147](https://bugs.python.org/issue?@action=redirect&bpo=26147) [https://bugs.python.org/issue?@action=redirect&bpo=26147]: `xmlrpc` now works with strings not encodable with used non-UTF-8 encoding.
- [bpo-25935](https://bugs.python.org/issue?@action=redirect&bpo=25935) [https://bugs.python.org/issue?@action=redirect&bpo=25935]: Garbage collector now breaks reference loops with `OrderedDict`.
- [bpo-16620](https://bugs.python.org/issue?@action=redirect&bpo=16620) [https://bugs.python.org/issue?@action=redirect&bpo=16620]: Fixed `AttributeError` in `msilib.Directory.glob()`.
- [bpo-26013](https://bugs.python.org/issue?@action=redirect&bpo=26013) [https://bugs.python.org/issue?@action=redirect&bpo=26013]: Added compatibility with broken protocol 2 pickles created in old Python 3 versions (3.4.3 and lower).
- [bpo-25850](https://bugs.python.org/issue?@action=redirect&bpo=25850) [https://bugs.python.org/issue?@action=redirect&bpo=25850]: Use cross-compilation by default for 64-bit Windows.
- [bpo-17633](https://bugs.python.org/issue?@action=redirect&bpo=17633) [https://bugs.python.org/issue?@action=redirect&bpo=17633]: Improve `zipimport`’s support for namespace packages.
- [bpo-24705](https://bugs.python.org/issue?@action=redirect&bpo=24705) [https://bugs.python.org/issue?@action=redirect&bpo=24705]

@action=redirect&bpo=24705]: Fix sysconfig.\_parse\_makefile not expanding \${} vars appearing before \$() vars.

- [bpo-22138](https://bugs.python.org/issue?@action=redirect&bpo=22138) [https://bugs.python.org/issue?@action=redirect&bpo=22138]: Fix mock.patch behavior when patching descriptors. Restore original values after patching. Patch contributed by Sean McCully.
- [bpo-25672](https://bugs.python.org/issue?@action=redirect&bpo=25672) [https://bugs.python.org/issue?@action=redirect&bpo=25672]: In the ssl module, enable the SSL\_MODE\_RELEASE\_BUFFERS mode option if it is safe to do so.
- [bpo-26012](https://bugs.python.org/issue?@action=redirect&bpo=26012) [https://bugs.python.org/issue?@action=redirect&bpo=26012]: Don't traverse into symlinks for \*\* pattern in pathlib.Path.[r]glob().
- [bpo-24120](https://bugs.python.org/issue?@action=redirect&bpo=24120) [https://bugs.python.org/issue?@action=redirect&bpo=24120]: Ignore PermissionError when traversing a tree with pathlib.Path.[r]glob(). Patch by Ulrich Petri.
- [bpo-25447](https://bugs.python.org/issue?@action=redirect&bpo=25447) [https://bugs.python.org/issue?@action=redirect&bpo=25447]: fileinput now uses sys.stdin as-is if it does not have a buffer attribute (restores backward compatibility).
- [bpo-25447](https://bugs.python.org/issue?@action=redirect&bpo=25447) [https://bugs.python.org/issue?@action=redirect&bpo=25447]: Copying the lru\_cache() wrapper object now always works, independently from the type of the wrapped object (by returning the original object unchanged).
- [bpo-24103](https://bugs.python.org/issue?@action=redirect&bpo=24103) [https://bugs.python.org/issue?@action=redirect&bpo=24103]: Fixed possible use after free in ElementTree.XMLPullParser.
- [bpo-25860](https://bugs.python.org/issue?@action=redirect&bpo=25860) [https://bugs.python.org/issue?@action=redirect&bpo=25860]: os.fwalk() no longer skips remaining directories when error occurs. Original patch by Samson Lee.
- [bpo-25914](https://bugs.python.org/issue?@action=redirect&bpo=25914) [https://bugs.python.org/issue?@action=redirect&bpo=25914]: Fixed and simplified OrderedDict.\_sizeof\_.
- [bpo-25902](https://bugs.python.org/issue?@action=redirect&bpo=25902) [https://bugs.python.org/issue?@action=redirect&bpo=25902]: Fixed various refcount issues in ElementTree iteration.
- [bpo-25717](https://bugs.python.org/issue?@action=redirect&bpo=25717) [https://bugs.python.org/issue?@action=redirect&bpo=25717]: Restore the previous behaviour of

tolerating most `fstat()` errors when opening files. This was a regression in 3.5a1, and stopped anonymous temporary files from working in special cases.

- [bpo-24903](https://bugs.python.org/issue?@action=redirect&bpo=24903) [https://bugs.python.org/issue?@action=redirect&bpo=24903]: Fix regression in number of arguments `compileall` accepts when `'-d'` is specified. The check on the number of arguments has been dropped completely as it never worked correctly anyway.
- [bpo-25764](https://bugs.python.org/issue?@action=redirect&bpo=25764) [https://bugs.python.org/issue?@action=redirect&bpo=25764]: In the `subprocess` module, preserve any exception caused by `fork()` failure when `preexec_fn` is used.
- [bpo-6478](https://bugs.python.org/issue?@action=redirect&bpo=6478) [https://bugs.python.org/issue?@action=redirect&bpo=6478]: `_strptime`'s regexp cache now is reset after changing timezone with `time.tzset()`.
- [bpo-14285](https://bugs.python.org/issue?@action=redirect&bpo=14285) [https://bugs.python.org/issue?@action=redirect&bpo=14285]: When executing a package with the `"python -m package"` option, and package initialization fails, a proper traceback is now reported. The `"runpy"` module now lets exceptions from package initialization pass back to the caller, rather than raising `ImportError`.
- [bpo-19771](https://bugs.python.org/issue?@action=redirect&bpo=19771) [https://bugs.python.org/issue?@action=redirect&bpo=19771]: Also in `runpy` and the `"-m"` option, omit the irrelevant message `"... is a package and cannot be directly executed"` if the package could not even be initialized (e.g. due to a bad `*.pyc` file).
- [bpo-25177](https://bugs.python.org/issue?@action=redirect&bpo=25177) [https://bugs.python.org/issue?@action=redirect&bpo=25177]: Fixed problem with the mean of very small and very large numbers. As a side effect, `statistics.mean` and `statistics.variance` should be significantly faster.
- [bpo-25718](https://bugs.python.org/issue?@action=redirect&bpo=25718) [https://bugs.python.org/issue?@action=redirect&bpo=25718]: Fixed copying object with state with boolean value is false.
- [bpo-10131](https://bugs.python.org/issue?@action=redirect&bpo=10131) [https://bugs.python.org/issue?@action=redirect&bpo=10131]: Fixed deep copying of `minidom` documents. Based on patch by Marian Ganisin.
- [bpo-25725](https://bugs.python.org/issue?@action=redirect&bpo=25725) [https://bugs.python.org/issue?@action=redirect&bpo=25725]: Fixed a reference leak in `pickle.loads()` when unpickling invalid data including tuple

instructions.

- [bpo-25663](https://bugs.python.org/issue?@action=redirect&bpo=25663) [https://bugs.python.org/issue?@action=redirect&bpo=25663]: In the Readline completer, avoid listing duplicate global names, and search the global namespace before searching builtins.
- [bpo-25688](https://bugs.python.org/issue?@action=redirect&bpo=25688) [https://bugs.python.org/issue?@action=redirect&bpo=25688]: Fixed file leak in `ElementTree.iterparse()` raising an error.
- [bpo-23914](https://bugs.python.org/issue?@action=redirect&bpo=23914) [https://bugs.python.org/issue?@action=redirect&bpo=23914]: Fixed `SystemError` raised by unpickler on broken pickle data.
- [bpo-25691](https://bugs.python.org/issue?@action=redirect&bpo=25691) [https://bugs.python.org/issue?@action=redirect&bpo=25691]: Fixed crash on deleting `ElementTree.Element` attributes.
- [bpo-25624](https://bugs.python.org/issue?@action=redirect&bpo=25624) [https://bugs.python.org/issue?@action=redirect&bpo=25624]: `ZipFile` now always writes a `ZIP_STORED` header for directory entries. Patch by Dingyuan Wang.
- Skip `getaddrinfo` if host is already resolved. Patch by A. Jesse Jiryu Davis.
- [bpo-26050](https://bugs.python.org/issue?@action=redirect&bpo=26050) [https://bugs.python.org/issue?@action=redirect&bpo=26050]: Add `asyncio.StreamReader.readuntil()` method. Patch by Mapк Копенбегр.
- [bpo-25924](https://bugs.python.org/issue?@action=redirect&bpo=25924) [https://bugs.python.org/issue?@action=redirect&bpo=25924]: Avoid unnecessary serialization of `getaddrinfo(3)` calls on OS X versions 10.5 or higher. Original patch by A. Jesse Jiryu Davis.
- [bpo-26406](https://bugs.python.org/issue?@action=redirect&bpo=26406) [https://bugs.python.org/issue?@action=redirect&bpo=26406]: Avoid unnecessary serialization of `getaddrinfo(3)` calls on current versions of OpenBSD and NetBSD. Patch by A. Jesse Jiryu Davis.
- [bpo-26848](https://bugs.python.org/issue?@action=redirect&bpo=26848) [https://bugs.python.org/issue?@action=redirect&bpo=26848]: Fix `asyncio/subprocess.communicate()` to handle empty input. Patch by Jack O'Connor.
- [bpo-27040](https://bugs.python.org/issue?@action=redirect&bpo=27040) [https://bugs.python.org/issue?@action=redirect&bpo=27040]: Add `loop.get_exception_handler` method
- [bpo-27041](https://bugs.python.org/issue?@action=redirect&bpo=27041) [https://bugs.python.org/issue?@action=redirect&bpo=27041]

@action=redirect&bpo=27041]: [asyncio: Add loop.create\\_future method](#)

- [bpo-27223](#) [<https://bugs.python.org/issue?@action=redirect&bpo=27223>]: [asyncio: Fix \\_read\\_ready and \\_write\\_ready to respect \\_conn\\_lost](#). Patch by Łukasz Langa.
- [bpo-22970](#) [<https://bugs.python.org/issue?@action=redirect&bpo=22970>]: [asyncio: Fix inconsistency cancelling Condition.wait](#). Patch by David Coles.

## IDLE

- [bpo-5124](#) [<https://bugs.python.org/issue?@action=redirect&bpo=5124>]: [Paste with text selected now replaces the selection on X11](#). This matches how paste works on Windows, Mac, most modern Linux apps, and ttk widgets. Original patch by Serhiy Storchaka.
- [bpo-24759](#) [<https://bugs.python.org/issue?@action=redirect&bpo=24759>]: [Make clear in idlelib.idle\\_test.\\_init\\_ that the directory is a private implementation of test.test\\_idle and tool for maintainers](#).
- [bpo-27196](#) [<https://bugs.python.org/issue?@action=redirect&bpo=27196>]: [Stop ‘ThemeChanged’ warnings when running IDLE tests](#). These persisted after other warnings were suppressed in #20567. Apply Serhiy Storchaka’s `update_idletasks` solution to four test files. Record this additional advice in `idle_test/README.txt`
- [bpo-20567](#) [<https://bugs.python.org/issue?@action=redirect&bpo=20567>]: [Revise idle\\_test/README.txt with advice about avoiding tk warning messages from tests](#). Apply advice to several IDLE tests.
- [bpo-27117](#) [<https://bugs.python.org/issue?@action=redirect&bpo=27117>]: [Make colorizer htest and turtledemo work with dark themes](#). Move code for configuring text widget colors to a new function.
- [bpo-26673](#) [<https://bugs.python.org/issue?@action=redirect&bpo=26673>]: [When tk reports font size as 0, change to size 10](#). Such fonts on Linux prevented the configuration dialog from opening.
- [bpo-21939](#) [<https://bugs.python.org/issue?@action=redirect&bpo=21939>]: [Add test for IDLE’s percolator](#).

Original patch by Saimadhav Heblikar.

- [bpo-21676](https://bugs.python.org/issue?@action=redirect&bpo=21676) [https://bugs.python.org/issue?@action=redirect&bpo=21676]: Add test for IDLE's replace dialog. Original patch by Saimadhav Heblikar.
- [bpo-18410](https://bugs.python.org/issue?@action=redirect&bpo=18410) [https://bugs.python.org/issue?@action=redirect&bpo=18410]: Add test for IDLE's search dialog. Original patch by Westley Martínez.
- [bpo-21703](https://bugs.python.org/issue?@action=redirect&bpo=21703) [https://bugs.python.org/issue?@action=redirect&bpo=21703]: Add test for IDLE's undo delegator. Original patch by Saimadhav Heblikar .
- [bpo-27044](https://bugs.python.org/issue?@action=redirect&bpo=27044) [https://bugs.python.org/issue?@action=redirect&bpo=27044]: Add ConfigDialog.remove\_var\_callbacks to stop memory leaks.
- [bpo-23977](https://bugs.python.org/issue?@action=redirect&bpo=23977) [https://bugs.python.org/issue?@action=redirect&bpo=23977]: Add more asserts to test\_delegator.
- [bpo-20640](https://bugs.python.org/issue?@action=redirect&bpo=20640) [https://bugs.python.org/issue?@action=redirect&bpo=20640]: Add tests for idlelib.configHelpSourceEdit. Patch by Saimadhav Heblikar.
- In the 'IDLE-console differences' section of the IDLE doc, clarify how running with IDLE affects sys.modules and the standard streams.
- [bpo-25507](https://bugs.python.org/issue?@action=redirect&bpo=25507) [https://bugs.python.org/issue?@action=redirect&bpo=25507]: fix incorrect change in IOBinding that prevented printing. Augment IOBinding htest to include all major IOBinding functions.
- [bpo-25905](https://bugs.python.org/issue?@action=redirect&bpo=25905) [https://bugs.python.org/issue?@action=redirect&bpo=25905]: Revert unwanted conversion of ' to ' RIGHT SINGLE QUOTATION MARK in README.txt and open this and NEWS.txt with 'ascii'. Re-encode CREDITS.txt to utf-8 and open it with 'utf-8'.

## Documentation

- [bpo-19489](https://bugs.python.org/issue?@action=redirect&bpo=19489) [https://bugs.python.org/issue?@action=redirect&bpo=19489]: Moved the search box from the sidebar to the header and footer of each page. Patch by Ammar Askar.
- [bpo-24136](https://bugs.python.org/issue?@action=redirect&bpo=24136) [https://bugs.python.org/issue?@action=redirect&bpo=24136]: Document the new **PEP 448**

[<https://peps.python.org/pep-0448/>] unpacking syntax of 3.5.

- [bpo-26736](#) [<https://bugs.python.org/issue?@action=redirect&bpo=26736>]: Used HTTPS for external links in the documentation if possible.
- [bpo-6953](#) [<https://bugs.python.org/issue?@action=redirect&bpo=6953>]: Rework the Readline module documentation to group related functions together, and add more details such as what underlying Readline functions and variables are accessed.
- [bpo-23606](#) [<https://bugs.python.org/issue?@action=redirect&bpo=23606>]: Adds note to ctypes documentation regarding `cdll.msvcrt`.
- [bpo-25500](#) [<https://bugs.python.org/issue?@action=redirect&bpo=25500>]: Fix documentation to not claim that `_import_` is searched for in the global scope.
- [bpo-26014](#) [<https://bugs.python.org/issue?@action=redirect&bpo=26014>]: Update 3.x packaging documentation: \* “See also” links to the new docs are now provided in the legacy pages \* links to setup tools documentation have been updated

## Tests

- [bpo-21916](#) [<https://bugs.python.org/issue?@action=redirect&bpo=21916>]: Added tests for the turtle module. Patch by ingrid, Gregory Loyse and Jelle Zijlstra.
- [bpo-26523](#) [<https://bugs.python.org/issue?@action=redirect&bpo=26523>]: The multiprocessing thread pool (`multiprocessing.dummy.Pool`) was untested.
- [bpo-26015](#) [<https://bugs.python.org/issue?@action=redirect&bpo=26015>]: Added new tests for pickling iterators of mutable sequences.
- [bpo-26325](#) [<https://bugs.python.org/issue?@action=redirect&bpo=26325>]: Added `test.support.check_no_resource_warning()` to check that no `ResourceWarning` is emitted.
- [bpo-25940](#) [<https://bugs.python.org/issue?@action=redirect&bpo=25940>]: Changed `test_ssl` to use self-signed.pythontest.net. This avoids relying on `svn.python.org`, which recently changed root certificate.
- [bpo-25616](#) [<https://bugs.python.org/issue?@action=redirect&bpo=25616>]

@action=redirect&bpo=25616]: Tests for OrderedDict are extracted from test\_collections into separate file test\_ordered\_dict.

- [bpo-26583](https://bugs.python.org/issue?@action=redirect&bpo=26583) [https://bugs.python.org/issue?@action=redirect&bpo=26583]: Skip test\_timestamp\_overflow in test\_import if bytecode files cannot be written.

## Build

- [bpo-26884](https://bugs.python.org/issue?@action=redirect&bpo=26884) [https://bugs.python.org/issue?@action=redirect&bpo=26884]: Fix linking extension modules for cross builds. Patch by Xavier de Gaye.
- [bpo-22359](https://bugs.python.org/issue?@action=redirect&bpo=22359) [https://bugs.python.org/issue?@action=redirect&bpo=22359]: Disable the rules for running \_freeze\_importlib and pgen when cross-compiling. The output of these programs is normally saved with the source code anyway, and is still regenerated when doing a native build. Patch by Xavier de Gaye.
- [bpo-27229](https://bugs.python.org/issue?@action=redirect&bpo=27229) [https://bugs.python.org/issue?@action=redirect&bpo=27229]: Fix the cross-compiling pgen rule for in-tree builds. Patch by Xavier de Gaye.
- [bpo-21668](https://bugs.python.org/issue?@action=redirect&bpo=21668) [https://bugs.python.org/issue?@action=redirect&bpo=21668]: Link audioop, \_datetime, \_ctypes\_test modules to libm, except on Mac OS X. Patch written by Xavier de Gaye.
- [bpo-25702](https://bugs.python.org/issue?@action=redirect&bpo=25702) [https://bugs.python.org/issue?@action=redirect&bpo=25702]: A -with-lto configure option has been added that will enable link time optimizations at build time during a make profile-opt. Some compilers and toolchains are known to not produce stable code when using LTO, be sure to test things thoroughly before relying on it. It can provide a few % speed up over profile-opt alone.
- [bpo-26624](https://bugs.python.org/issue?@action=redirect&bpo=26624) [https://bugs.python.org/issue?@action=redirect&bpo=26624]: Adds validation of ucrtbase[d].dll version with warning for old versions.
- [bpo-17603](https://bugs.python.org/issue?@action=redirect&bpo=17603) [https://bugs.python.org/issue?@action=redirect&bpo=17603]: Avoid error about nonexistent fileblocks.o file by using a lower-level check for st\_blocks in struct stat.
- [bpo-26079](https://bugs.python.org/issue?@action=redirect&bpo=26079) [https://bugs.python.org/issue?@action=redirect&bpo=26079]

@action=redirect&bpo=26079]: Fixing the build output folder for tix-8.4.3.6. Patch by Bjoern Thiel.

- [bpo-26465](https://bugs.python.org/issue?@action=redirect&bpo=26465) [https://bugs.python.org/issue?@action=redirect&bpo=26465]: Update Windows builds to use OpenSSL 1.0.2g.
- [bpo-24421](https://bugs.python.org/issue?@action=redirect&bpo=24421) [https://bugs.python.org/issue?@action=redirect&bpo=24421]: Compile Modules/\_math.c once, before building extensions. Previously it could fail to compile properly if the math and cmath builds were concurrent.
- [bpo-25348](https://bugs.python.org/issue?@action=redirect&bpo=25348) [https://bugs.python.org/issue?@action=redirect&bpo=25348]: Added --pgo and --pgo-job arguments to PCbuild\build.bat for building with Profile-Guided Optimization. The old PCbuild\build\_pgo.bat script is now deprecated, and simply calls PCbuild\build.bat --pgo %\*.
- [bpo-25827](https://bugs.python.org/issue?@action=redirect&bpo=25827) [https://bugs.python.org/issue?@action=redirect&bpo=25827]: Add support for building with ICC to configure, including a new --with-icc flag.
- [bpo-25696](https://bugs.python.org/issue?@action=redirect&bpo=25696) [https://bugs.python.org/issue?@action=redirect&bpo=25696]: Fix installation of Python on UNIX with make -j9.
- [bpo-26930](https://bugs.python.org/issue?@action=redirect&bpo=26930) [https://bugs.python.org/issue?@action=redirect&bpo=26930]: Update OS X 10.5+ 32-bit-only installer to build and link with OpenSSL 1.0.2h.
- [bpo-26268](https://bugs.python.org/issue?@action=redirect&bpo=26268) [https://bugs.python.org/issue?@action=redirect&bpo=26268]: Update Windows builds to use OpenSSL 1.0.2f.
- [bpo-25136](https://bugs.python.org/issue?@action=redirect&bpo=25136) [https://bugs.python.org/issue?@action=redirect&bpo=25136]: Support Apple Xcode 7's new textual SDK stub libraries.
- [bpo-24324](https://bugs.python.org/issue?@action=redirect&bpo=24324) [https://bugs.python.org/issue?@action=redirect&bpo=24324]: Do not enable unreachable code warnings when using gcc as the option does not work correctly in older versions of gcc and has been silently removed as of gcc-4.5.

## Windows

- [bpo-27053](https://bugs.python.org/issue?@action=redirect&bpo=27053) [https://bugs.python.org/issue?@action=redirect&bpo=27053]: Updates make\_zip.py to correctly

generate library ZIP file.

- [bpo-26268](https://bugs.python.org/issue?@action=redirect&bpo=26268) [https://bugs.python.org/issue?@action=redirect&bpo=26268]: Update the prepare\_ssl.py script to handle OpenSSL releases that don't include the contents of the include directory (that is, 1.0.2e and later).
- [bpo-26071](https://bugs.python.org/issue?@action=redirect&bpo=26071) [https://bugs.python.org/issue?@action=redirect&bpo=26071]: bdist\_wininst created binaries fail to start and find 32bit Python
- [bpo-26073](https://bugs.python.org/issue?@action=redirect&bpo=26073) [https://bugs.python.org/issue?@action=redirect&bpo=26073]: Update the list of magic numbers in launcher
- [bpo-26065](https://bugs.python.org/issue?@action=redirect&bpo=26065) [https://bugs.python.org/issue?@action=redirect&bpo=26065]: Excludes venv from library when generating embeddable distro.
- [bpo-17500](https://bugs.python.org/issue?@action=redirect&bpo=17500) [https://bugs.python.org/issue?@action=redirect&bpo=17500]: Remove unused and outdated icons. (See also: <https://github.com/python/pythondotorg/issues/945>)

## Tools/Demos

- [bpo-26799](https://bugs.python.org/issue?@action=redirect&bpo=26799) [https://bugs.python.org/issue?@action=redirect&bpo=26799]: Fix python-gdb.py: don't get C types once when the Python code is loaded, but get C types on demand. The C types can change if python-gdb.py is loaded before the Python executable. Patch written by Thomas Ilsche.
- [bpo-26271](https://bugs.python.org/issue?@action=redirect&bpo=26271) [https://bugs.python.org/issue?@action=redirect&bpo=26271]: Fix the Freeze tool to properly use flags passed through configure. Patch by Daniel Shaulov.
- [bpo-26489](https://bugs.python.org/issue?@action=redirect&bpo=26489) [https://bugs.python.org/issue?@action=redirect&bpo=26489]: Add dictionary unpacking support to Tools/parser/unparse.py. Patch by Guo Ci Teo.
- [bpo-26316](https://bugs.python.org/issue?@action=redirect&bpo=26316) [https://bugs.python.org/issue?@action=redirect&bpo=26316]: Fix variable name typo in Argument Clinic.

## Python 3.5.1 final

*Release date: 2015-12-06*

## Core and Builtins

- [bpo-25709](https://bugs.python.org/issue?@action=redirect&bpo=25709) [https://bugs.python.org/issue?@action=redirect&bpo=25709]: Fixed problem with in-place string concatenation and utf-8 cache.

## Windows

- [bpo-25715](https://bugs.python.org/issue?@action=redirect&bpo=25715) [https://bugs.python.org/issue?@action=redirect&bpo=25715]: Python 3.5.1 installer shows wrong upgrade path and incorrect logic for launcher detection.

# Python 3.5.1 release candidate 1

*Release date: 2015-11-22*

## Core and Builtins

- [bpo-25630](https://bugs.python.org/issue?@action=redirect&bpo=25630) [https://bugs.python.org/issue?@action=redirect&bpo=25630]: Fix a possible segfault during argument parsing in functions that accept filesystem paths.
- [bpo-23564](https://bugs.python.org/issue?@action=redirect&bpo=23564) [https://bugs.python.org/issue?@action=redirect&bpo=23564]: Fixed a partially broken sanity check in the `_posixsubprocess` internals regarding how `fds_to_pass` were passed to the child. The bug had no actual impact as `subprocess.py` already avoided it.
- [bpo-25388](https://bugs.python.org/issue?@action=redirect&bpo=25388) [https://bugs.python.org/issue?@action=redirect&bpo=25388]: Fixed tokenizer crash when processing undecodable source code with a null byte.
- [bpo-25462](https://bugs.python.org/issue?@action=redirect&bpo=25462) [https://bugs.python.org/issue?@action=redirect&bpo=25462]: The hash of the key now is calculated only once in most operations in C implementation of `OrderedDict`.
- [bpo-22995](https://bugs.python.org/issue?@action=redirect&bpo=22995) [https://bugs.python.org/issue?@action=redirect&bpo=22995]: Default implementation of `_reduce_` and `_reduce_ex_` now rejects builtin types with not

defined `_new_`.

- [bpo-25555](https://bugs.python.org/issue?@action=redirect&bpo=25555) [https://bugs.python.org/issue?@action=redirect&bpo=25555]: Fix parser and AST: fill `lineno` and `col_offset` of “arg” node when compiling AST from Python objects.
- [bpo-24802](https://bugs.python.org/issue?@action=redirect&bpo=24802) [https://bugs.python.org/issue?@action=redirect&bpo=24802]: Avoid buffer overreads when `int()`, `float()`, `compile()`, `exec()` and `eval()` are passed bytes-like objects. These objects are not necessarily terminated by a null byte, but the functions assumed they were.
- [bpo-24726](https://bugs.python.org/issue?@action=redirect&bpo=24726) [https://bugs.python.org/issue?@action=redirect&bpo=24726]: Fixed a crash and leaking NULL in `repr()` of `OrderedDict` that was mutated by direct calls of dict methods.
- [bpo-25449](https://bugs.python.org/issue?@action=redirect&bpo=25449) [https://bugs.python.org/issue?@action=redirect&bpo=25449]: Iterating `OrderedDict` with keys with unstable hash now raises `KeyError` in C implementations as well as in Python implementation.
- [bpo-25395](https://bugs.python.org/issue?@action=redirect&bpo=25395) [https://bugs.python.org/issue?@action=redirect&bpo=25395]: Fixed crash when highly nested `OrderedDict` structures were garbage collected.
- [bpo-25274](https://bugs.python.org/issue?@action=redirect&bpo=25274) [https://bugs.python.org/issue?@action=redirect&bpo=25274]: `sys.setrecursionlimit()` now raises a `RecursionError` if the new recursion limit is too low depending at the current recursion depth. Modify also the “lower-water mark” formula to make it monotonic. This mark is used to decide when the overflowed flag of the thread state is reset.
- [bpo-24402](https://bugs.python.org/issue?@action=redirect&bpo=24402) [https://bugs.python.org/issue?@action=redirect&bpo=24402]: Fix `input()` to prompt to the redirected stdout when `sys.stdout.fileno()` fails.
- [bpo-24806](https://bugs.python.org/issue?@action=redirect&bpo=24806) [https://bugs.python.org/issue?@action=redirect&bpo=24806]: Prevent builtin types that are not allowed to be subclassed from being subclassed through multiple inheritance.
- [bpo-24848](https://bugs.python.org/issue?@action=redirect&bpo=24848) [https://bugs.python.org/issue?@action=redirect&bpo=24848]: Fixed a number of bugs in UTF-7 decoding of misformed data.
- [bpo-25280](https://bugs.python.org/issue?@action=redirect&bpo=25280) [https://bugs.python.org/issue?@action=redirect&bpo=25280]: Import trace messages emitted in

verbose (-v) mode are no longer formatted twice.

- [bpo-25003](https://bugs.python.org/issue?@action=redirect&bpo=25003) [https://bugs.python.org/issue?@action=redirect&bpo=25003]: On Solaris 11.3 or newer, `os.urandom()` now uses the `getrandom()` function instead of the `getentropy()` function. The `getentropy()` function is blocking to generate very good quality entropy, `os.urandom()` doesn't need such high-quality entropy.
- [bpo-25182](https://bugs.python.org/issue?@action=redirect&bpo=25182) [https://bugs.python.org/issue?@action=redirect&bpo=25182]: The `stdprinter` (used as `sys.stderr` before the `io` module is imported at startup) now uses the `backslashreplace` error handler.
- [bpo-25131](https://bugs.python.org/issue?@action=redirect&bpo=25131) [https://bugs.python.org/issue?@action=redirect&bpo=25131]: Make the line number and column offset of `set/dict` literals and comprehensions correspond to the opening brace.
- [bpo-25150](https://bugs.python.org/issue?@action=redirect&bpo=25150) [https://bugs.python.org/issue?@action=redirect&bpo=25150]: Hide the private `_Py_atomic_XXX` symbols from the public `Python.h` header to fix a compilation error with OpenMP. `PyThreadState_GET()` becomes an alias to `PyThreadState_Get()` to avoid ABI incompatibilities.

## Library

- [bpo-25626](https://bugs.python.org/issue?@action=redirect&bpo=25626) [https://bugs.python.org/issue?@action=redirect&bpo=25626]: Change three `zlib` functions to accept sizes that fit in `Py_ssize_t`, but internally cap those sizes to `UINT_MAX`. This resolves a regression in 3.5 where `GzipFile.read()` failed to read chunks larger than 2 or 4 GiB. The change affects the `zlib.Decompress.decompress()` `max_length` parameter, the `zlib.decompress()` `bufsize` parameter, and the `zlib.Decompress.flush()` `length` parameter.
- [bpo-25583](https://bugs.python.org/issue?@action=redirect&bpo=25583) [https://bugs.python.org/issue?@action=redirect&bpo=25583]: Avoid incorrect errors raised by `os.makedirs(exist_ok=True)` when the OS gives priority to errors such as `EACCES` over `EEXIST`.
- [bpo-25593](https://bugs.python.org/issue?@action=redirect&bpo=25593) [https://bugs.python.org/issue?@action=redirect&bpo=25593]: Change semantics of `EventLoop.stop()` in `asyncio`.
- [bpo-6973](https://bugs.python.org/issue?@action=redirect&bpo=6973) [https://bugs.python.org/issue?@action=redirect&bpo=6973]: When we know a `subprocess.Popen` process has died, do not

allow the `send_signal()`, `terminate()`, or `kill()` methods to do anything as they could potentially signal a different process.

- [bpo-25590](https://bugs.python.org/issue?@action=redirect&bpo=25590) [https://bugs.python.org/issue?@action=redirect&bpo=25590]: In the Readline completer, only call `getattr()` once per attribute.
- [bpo-25498](https://bugs.python.org/issue?@action=redirect&bpo=25498) [https://bugs.python.org/issue?@action=redirect&bpo=25498]: Fix a crash when garbage-collecting ctypes objects created by wrapping a memoryview. This was a regression made in 3.5a1. Based on patch by Eryksun.
- [bpo-25584](https://bugs.python.org/issue?@action=redirect&bpo=25584) [https://bugs.python.org/issue?@action=redirect&bpo=25584]: Added “escape” to the `_all_` list in the `glob` module.
- [bpo-25584](https://bugs.python.org/issue?@action=redirect&bpo=25584) [https://bugs.python.org/issue?@action=redirect&bpo=25584]: Fixed recursive `glob()` with patterns starting with `* * *`.
- [bpo-25446](https://bugs.python.org/issue?@action=redirect&bpo=25446) [https://bugs.python.org/issue?@action=redirect&bpo=25446]: Fix regression in `smtplib`’s AUTH LOGIN support.
- [bpo-18010](https://bugs.python.org/issue?@action=redirect&bpo=18010) [https://bugs.python.org/issue?@action=redirect&bpo=18010]: Fix the `pydoc` web server’s module search function to handle exceptions from importing packages.
- [bpo-25554](https://bugs.python.org/issue?@action=redirect&bpo=25554) [https://bugs.python.org/issue?@action=redirect&bpo=25554]: Got rid of circular references in regular expression parsing.
- [bpo-25510](https://bugs.python.org/issue?@action=redirect&bpo=25510) [https://bugs.python.org/issue?@action=redirect&bpo=25510]: `fileinput.FileInput.readline()` now returns `b”` instead of `”` at the end if the `FileInput` was opened with binary mode. Patch by Ryosuke Ito.
- [bpo-25503](https://bugs.python.org/issue?@action=redirect&bpo=25503) [https://bugs.python.org/issue?@action=redirect&bpo=25503]: Fixed `inspect.getdoc()` for inherited docstrings of properties. Original patch by John Mark Vandenberg.
- [bpo-25515](https://bugs.python.org/issue?@action=redirect&bpo=25515) [https://bugs.python.org/issue?@action=redirect&bpo=25515]: Always use `os.urandom` as a source of randomness in `uuid.uuid4`.
- [bpo-21827](https://bugs.python.org/issue?@action=redirect&bpo=21827) [https://bugs.python.org/issue?@action=redirect&bpo=21827]: Fixed `textwrap.dedent()` for the case when largest common whitespace is a substring of

smallest leading whitespace. Based on patch by Robert Li.

- [bpo-25447](https://bugs.python.org/issue?@action=redirect&bpo=25447) [https://bugs.python.org/issue?@action=redirect&bpo=25447]: The `lru_cache()` wrapper objects now can be copied and pickled (by returning the original object unchanged).
- [bpo-25390](https://bugs.python.org/issue?@action=redirect&bpo=25390) [https://bugs.python.org/issue?@action=redirect&bpo=25390]: typing: Don't crash on `Union[str, Pattern]`.
- [bpo-25441](https://bugs.python.org/issue?@action=redirect&bpo=25441) [https://bugs.python.org/issue?@action=redirect&bpo=25441]: asyncio: Raise error from `drain()` when socket is closed.
- [bpo-25410](https://bugs.python.org/issue?@action=redirect&bpo=25410) [https://bugs.python.org/issue?@action=redirect&bpo=25410]: Cleaned up and fixed minor bugs in C implementation of `OrderedDict`.
- [bpo-25411](https://bugs.python.org/issue?@action=redirect&bpo=25411) [https://bugs.python.org/issue?@action=redirect&bpo=25411]: Improved Unicode support in `SMTPHandler` through better use of the email package. Thanks to user `simon04` for the patch.
- [bpo-25407](https://bugs.python.org/issue?@action=redirect&bpo=25407) [https://bugs.python.org/issue?@action=redirect&bpo=25407]: Remove mentions of the formatter module being removed in Python 3.6.
- [bpo-25406](https://bugs.python.org/issue?@action=redirect&bpo=25406) [https://bugs.python.org/issue?@action=redirect&bpo=25406]: Fixed a bug in C implementation of `OrderedDict.move_to_end()` that caused segmentation fault or hang in iterating after moving several items to the start of ordered dict.
- [bpo-25364](https://bugs.python.org/issue?@action=redirect&bpo=25364) [https://bugs.python.org/issue?@action=redirect&bpo=25364]: `zipfile` now works in threads disabled builds.
- [bpo-25328](https://bugs.python.org/issue?@action=redirect&bpo=25328) [https://bugs.python.org/issue?@action=redirect&bpo=25328]: `smtpd`'s `SMTPChannel` now correctly raises a `ValueError` if both `decode_data` and `enable_SMTPUTF8` are set to true.
- [bpo-25316](https://bugs.python.org/issue?@action=redirect&bpo=25316) [https://bugs.python.org/issue?@action=redirect&bpo=25316]: `distutils` raises `OSError` instead of `DistutilsPlatformError` when `MSVC` is not installed.
- [bpo-25380](https://bugs.python.org/issue?@action=redirect&bpo=25380) [https://bugs.python.org/issue?@action=redirect&bpo=25380]: Fixed protocol for the `STACK_GLOBAL` opcode in `pickletools.opcodes`.
- [bpo-23972](https://bugs.python.org/issue?@action=redirect&bpo=23972) [https://bugs.python.org/issue?@action=redirect&bpo=23972]

@action=redirect&bpo=23972]: Updates `asyncio` datagram create method allowing `reuseport` and `reuseaddr` socket options to be set prior to binding the socket. Mirroring the existing `asyncio` `create_server` method the `reuseaddr` option for datagram sockets defaults to `True` if the O/S is 'posix' (except if the platform is `Cygwin`). Patch by Chris Laws.

- [bpo-25304](https://bugs.python.org/issue?@action=redirect&bpo=25304) [https://bugs.python.org/issue?@action=redirect&bpo=25304]: Add `asyncio.run_coroutine_threadsafe()`. This lets you submit a coroutine to a loop from another thread, returning a `concurrent.futures.Future`. By Vincent Michel.
- [bpo-25232](https://bugs.python.org/issue?@action=redirect&bpo=25232) [https://bugs.python.org/issue?@action=redirect&bpo=25232]: Fix `CGIRequestHandler` to split the query from the URL at the first question mark (?) rather than the last. Patch from Xiang Zhang.
- [bpo-24657](https://bugs.python.org/issue?@action=redirect&bpo=24657) [https://bugs.python.org/issue?@action=redirect&bpo=24657]: Prevent `CGIRequestHandler` from collapsing slashes in the query part of the URL as if it were a path. Patch from Xiang Zhang.
- [bpo-24483](https://bugs.python.org/issue?@action=redirect&bpo=24483) [https://bugs.python.org/issue?@action=redirect&bpo=24483]: `C` implementation of `functools.lru_cache()` now calculates key's hash only once.
- [bpo-22958](https://bugs.python.org/issue?@action=redirect&bpo=22958) [https://bugs.python.org/issue?@action=redirect&bpo=22958]: Constructor and update method of `weakref.WeakValueDictionary` now accept the `self` and the `dict` keyword arguments.
- [bpo-22609](https://bugs.python.org/issue?@action=redirect&bpo=22609) [https://bugs.python.org/issue?@action=redirect&bpo=22609]: Constructor of `collections.UserDict` now accepts the `self` keyword argument.
- [bpo-25111](https://bugs.python.org/issue?@action=redirect&bpo=25111) [https://bugs.python.org/issue?@action=redirect&bpo=25111]: Fixed comparison of `traceback.FrameSummary`.
- [bpo-25262](https://bugs.python.org/issue?@action=redirect&bpo=25262) [https://bugs.python.org/issue?@action=redirect&bpo=25262]: Added support for `BINBYTES8` opcode in Python implementation of unpickler. Highest 32 bits of 64-bit size for `BINUNICODE8` and `BINBYTES8` opcodes no longer silently ignored on 32-bit platforms in C implementation.
- [bpo-25034](https://bugs.python.org/issue?@action=redirect&bpo=25034) [https://bugs.python.org/issue?@action=redirect&bpo=25034]: Fix `string.Formatter` problem with

auto-numbering and nested format\_specs. Patch by Anthon van der Neut.

- [bpo-25233](https://bugs.python.org/issue?@action=redirect&bpo=25233) [https://bugs.python.org/issue?@action=redirect&bpo=25233]: Rewrite the guts of `asyncio.Queue` and `asyncio.Semaphore` to be more understandable and correct.
- [bpo-25203](https://bugs.python.org/issue?@action=redirect&bpo=25203) [https://bugs.python.org/issue?@action=redirect&bpo=25203]: Failed `readline.set_completer_delims()` no longer left the module in inconsistent state.
- [bpo-23600](https://bugs.python.org/issue?@action=redirect&bpo=23600) [https://bugs.python.org/issue?@action=redirect&bpo=23600]: Default implementation of `tzinfo.fromutc()` was returning wrong results in some cases.
- [bpo-23329](https://bugs.python.org/issue?@action=redirect&bpo=23329) [https://bugs.python.org/issue?@action=redirect&bpo=23329]: Allow the `ssl` module to be built with older versions of LibreSSL.
- Prevent overflow in `_Unpickler_Read`.
- [bpo-25047](https://bugs.python.org/issue?@action=redirect&bpo=25047) [https://bugs.python.org/issue?@action=redirect&bpo=25047]: The XML encoding declaration written by `Element Tree` now respects the letter case given by the user. This restores the ability to write encoding names in uppercase like “UTF-8”, which worked in Python 2.
- [bpo-25135](https://bugs.python.org/issue?@action=redirect&bpo=25135) [https://bugs.python.org/issue?@action=redirect&bpo=25135]: Make `deque_clear()` safer by emptying the deque before clearing. This helps avoid possible reentrancy issues.
- [bpo-19143](https://bugs.python.org/issue?@action=redirect&bpo=19143) [https://bugs.python.org/issue?@action=redirect&bpo=19143]: `platform` module now reads Windows version from `kernel32.dll` to avoid compatibility shims.
- [bpo-25092](https://bugs.python.org/issue?@action=redirect&bpo=25092) [https://bugs.python.org/issue?@action=redirect&bpo=25092]: Fix `datetime.strptime()` failure when `errno` was already set to `EINVAL`.
- [bpo-23517](https://bugs.python.org/issue?@action=redirect&bpo=23517) [https://bugs.python.org/issue?@action=redirect&bpo=23517]: Fix rounding in `fromtimestamp()` and `utcfromtimestamp()` methods of `datetime.datetime`: microseconds are now rounded to nearest with ties going to nearest even integer (`ROUND_HALF_EVEN`), instead of being rounding towards minus infinity (`ROUND_FLOOR`). It’s important that these methods use the same rounding mode

than `datetime.timedelta` to keep the property:  
`(datetime(1970,1,1) + timedelta(seconds=t)) == datetime.utcnow().timestamp(t)`. It also the rounding mode used by `round(float)` for example.

- [bpo-25155](https://bugs.python.org/issue?@action=redirect&bpo=25155) [https://bugs.python.org/issue?@action=redirect&bpo=25155]: Fix `datetime.datetime.now()` and `datetime.datetime.utcnow()` on Windows to support date after year 2038. It was a regression introduced in Python 3.5.0.
- [bpo-25108](https://bugs.python.org/issue?@action=redirect&bpo=25108) [https://bugs.python.org/issue?@action=redirect&bpo=25108]: Omitted internal frames in `traceback` functions `print_stack()`, `format_stack()`, and `extract_stack()` called without arguments.
- [bpo-25118](https://bugs.python.org/issue?@action=redirect&bpo=25118) [https://bugs.python.org/issue?@action=redirect&bpo=25118]: Fix a regression of Python 3.5.0 in `os.waitpid()` on Windows.
- [bpo-24684](https://bugs.python.org/issue?@action=redirect&bpo=24684) [https://bugs.python.org/issue?@action=redirect&bpo=24684]: `socket.getaddrinfo()` now calls `PyUnicode_AsEncodedString()` instead of calling the `encode()` method of the host, to handle correctly custom string with an `encode()` method which doesn't return a byte string. The encoder of the IDNA codec is now called directly instead of calling the `encode()` method of the string.
- [bpo-25060](https://bugs.python.org/issue?@action=redirect&bpo=25060) [https://bugs.python.org/issue?@action=redirect&bpo=25060]: Correctly compute stack usage of the `BUILD_MAP` opcode.
- [bpo-24857](https://bugs.python.org/issue?@action=redirect&bpo=24857) [https://bugs.python.org/issue?@action=redirect&bpo=24857]: Comparing `call_args` to a long sequence now correctly returns a boolean result instead of raising an exception. Patch by A Kaptur.
- [bpo-23144](https://bugs.python.org/issue?@action=redirect&bpo=23144) [https://bugs.python.org/issue?@action=redirect&bpo=23144]: Make sure that `HTMLParser.feed()` returns all the data, even when `convert_charrefs` is `True`.
- [bpo-24982](https://bugs.python.org/issue?@action=redirect&bpo=24982) [https://bugs.python.org/issue?@action=redirect&bpo=24982]: `shutil.make_archive()` with the "zip" format now adds entries for directories (including empty directories) in ZIP file.
- [bpo-25019](https://bugs.python.org/issue?@action=redirect&bpo=25019) [https://bugs.python.org/issue?@action=redirect&bpo=25019]: Fixed a crash caused by setting non-string key of `expat` parser. Based on patch by John

Leitch.

- [bpo-16180](https://bugs.python.org/issue?@action=redirect&bpo=16180) [https://bugs.python.org/issue?@action=redirect&bpo=16180]: Exit pdb if file has syntax error, instead of trapping user in an infinite loop. Patch by Xavier de Gaye.
- [bpo-24891](https://bugs.python.org/issue?@action=redirect&bpo=24891) [https://bugs.python.org/issue?@action=redirect&bpo=24891]: Fix a race condition at Python startup if the file descriptor of stdin (0), stdout (1) or stderr (2) is closed while Python is creating sys.stdin, sys.stdout and sys.stderr objects. These attributes are now set to None if the creation of the object failed, instead of raising an OSError exception. Initial patch written by Marco Paolini.
- [bpo-24992](https://bugs.python.org/issue?@action=redirect&bpo=24992) [https://bugs.python.org/issue?@action=redirect&bpo=24992]: Fix error handling and a race condition (related to garbage collection) in collections.OrderedDict constructor.
- [bpo-24881](https://bugs.python.org/issue?@action=redirect&bpo=24881) [https://bugs.python.org/issue?@action=redirect&bpo=24881]: Fixed setting binary mode in Python implementation of FileIO on Windows and Cygwin. Patch from Akira Li.
- [bpo-25578](https://bugs.python.org/issue?@action=redirect&bpo=25578) [https://bugs.python.org/issue?@action=redirect&bpo=25578]: Fix (another) memory leak in SSLSocket.getpeerercer().
- [bpo-25530](https://bugs.python.org/issue?@action=redirect&bpo=25530) [https://bugs.python.org/issue?@action=redirect&bpo=25530]: Disable the vulnerable SSLv3 protocol by default when creating ssl.SSLContext.
- [bpo-25569](https://bugs.python.org/issue?@action=redirect&bpo=25569) [https://bugs.python.org/issue?@action=redirect&bpo=25569]: Fix memory leak in SSLSocket.getpeerercert().
- [bpo-25471](https://bugs.python.org/issue?@action=redirect&bpo=25471) [https://bugs.python.org/issue?@action=redirect&bpo=25471]: Sockets returned from accept() shouldn't appear to be nonblocking.
- [bpo-25319](https://bugs.python.org/issue?@action=redirect&bpo=25319) [https://bugs.python.org/issue?@action=redirect&bpo=25319]: When threading.Event is reinitialized, the underlying condition should use a regular lock rather than a recursive lock.
- [bpo-21112](https://bugs.python.org/issue?@action=redirect&bpo=21112) [https://bugs.python.org/issue?@action=redirect&bpo=21112]: Fix regression in unittest.expectedFailure on subclasses. Patch from Berker Peksag.

- [bpo-24764](https://bugs.python.org/issue?@action=redirect&bpo=24764) [https://bugs.python.org/issue?@action=redirect&bpo=24764]: `cgi.FieldStorage.read_multi()` now ignores the Content-Length header in part headers. Patch written by Peter Landry and reviewed by Pierre Quentel.
- [bpo-24913](https://bugs.python.org/issue?@action=redirect&bpo=24913) [https://bugs.python.org/issue?@action=redirect&bpo=24913]: Fix overrun error in `deque.index()`. Found by John Leitch and Bryce Darling.
- [bpo-24774](https://bugs.python.org/issue?@action=redirect&bpo=24774) [https://bugs.python.org/issue?@action=redirect&bpo=24774]: Fix docstring in `http.server.test`. Patch from Chiu-Hsiang Hsu.
- [bpo-21159](https://bugs.python.org/issue?@action=redirect&bpo=21159) [https://bugs.python.org/issue?@action=redirect&bpo=21159]: Improve message in `configparser.InterpolationMissingOptionError`. Patch from Łukasz Langa.
- [bpo-20362](https://bugs.python.org/issue?@action=redirect&bpo=20362) [https://bugs.python.org/issue?@action=redirect&bpo=20362]: Honour `TestCase.longMessage` correctly in `assertRegex`. Patch from Ilia Kurenkov.
- [bpo-23572](https://bugs.python.org/issue?@action=redirect&bpo=23572) [https://bugs.python.org/issue?@action=redirect&bpo=23572]: Fixed `functools singledispatch` on classes with falsy metaclasses. Patch by Ethan Furman.
- `asyncio`: `ensure_future()` now accepts awaitable objects.

## IDLE

- [bpo-15348](https://bugs.python.org/issue?@action=redirect&bpo=15348) [https://bugs.python.org/issue?@action=redirect&bpo=15348]: Stop the debugger engine (normally in a user process) before closing the debugger window (running in the IDLE process). This prevents the RuntimeErrors that were being caught and ignored.
- [bpo-24455](https://bugs.python.org/issue?@action=redirect&bpo=24455) [https://bugs.python.org/issue?@action=redirect&bpo=24455]: Prevent IDLE from hanging when a) closing the shell while the debugger is active (15347); b) closing the debugger with the [X] button (15348); and c) activating the debugger when already active (24455). The patch by Mark Roseman does this by making two changes. 1. Suspend and resume the `gui.interaction` method with the `tcl vwait` mechanism intended for this purpose (instead of `root.mainloop & .quit`). 2. In `gui.run`, allow any existing interaction to terminate first.
- Change ‘The program’ to ‘Your program’ in an IDLE ‘kill

program?’ message to make it clearer that the program referred to is the currently running user program, not IDLE itself.

- [bpo-24750](https://bugs.python.org/issue?@action=redirect&bpo=24750) [https://bugs.python.org/issue?@action=redirect&bpo=24750]: Improve the appearance of the IDLE editor window status bar. Patch by Mark Roseman.
- [bpo-25313](https://bugs.python.org/issue?@action=redirect&bpo=25313) [https://bugs.python.org/issue?@action=redirect&bpo=25313]: Change the handling of new built-in text color themes to better address the compatibility problem introduced by the addition of IDLE Dark. Consistently use the revised `idleConf.CurrentTheme` everywhere in `idlelib`.
- [bpo-24782](https://bugs.python.org/issue?@action=redirect&bpo=24782) [https://bugs.python.org/issue?@action=redirect&bpo=24782]: Extension configuration is now a tab in the IDLE Preferences dialog rather than a separate dialog. The former tabs are now a sorted list. Patch by Mark Roseman.
- [bpo-22726](https://bugs.python.org/issue?@action=redirect&bpo=22726) [https://bugs.python.org/issue?@action=redirect&bpo=22726]: Re-activate the config dialog help button with some content about the other buttons and the new IDLE Dark theme.
- [bpo-24820](https://bugs.python.org/issue?@action=redirect&bpo=24820) [https://bugs.python.org/issue?@action=redirect&bpo=24820]: IDLE now has an ‘IDLE Dark’ built-in text color theme. It is more or less IDLE Classic inverted, with a cobalt blue background. Strings, comments, keywords, ... are still green, red, orange, ... . To use it with IDLEs released before November 2015, hit the ‘Save as New Custom Theme’ button and enter a new name, such as ‘Custom Dark’. The custom theme will work with any IDLE release, and can be modified.
- [bpo-25224](https://bugs.python.org/issue?@action=redirect&bpo=25224) [https://bugs.python.org/issue?@action=redirect&bpo=25224]: `README.txt` is now an `idlelib` index for IDLE developers and curious users. The previous user content is now in the IDLE doc chapter. ‘IDLE’ now means ‘Integrated Development and Learning Environment’.
- [bpo-24820](https://bugs.python.org/issue?@action=redirect&bpo=24820) [https://bugs.python.org/issue?@action=redirect&bpo=24820]: Users can now set breakpoint colors in Settings -> Custom Highlighting. Original patch by Mark Roseman.
- [bpo-24972](https://bugs.python.org/issue?@action=redirect&bpo=24972) [https://bugs.python.org/issue?@action=redirect&bpo=24972]

@action=redirect&bpo=24972]: Inactive selection background now matches active selection background, as configured by users, on all systems. Found items are now always highlighted on Windows. Initial patch by Mark Roseman.

- [bpo-24570](https://bugs.python.org/issue?@action=redirect&bpo=24570) [https://bugs.python.org/issue?@action=redirect&bpo=24570]: Idle: make calltip and completion boxes appear on Macs affected by a tk regression. Initial patch by Mark Roseman.
- [bpo-24988](https://bugs.python.org/issue?@action=redirect&bpo=24988) [https://bugs.python.org/issue?@action=redirect&bpo=24988]: Idle ScrolledList context menus (used in debugger) now work on Mac Aqua. Patch by Mark Roseman.
- [bpo-24801](https://bugs.python.org/issue?@action=redirect&bpo=24801) [https://bugs.python.org/issue?@action=redirect&bpo=24801]: Make right-click for context menu work on Mac Aqua. Patch by Mark Roseman.
- [bpo-25173](https://bugs.python.org/issue?@action=redirect&bpo=25173) [https://bugs.python.org/issue?@action=redirect&bpo=25173]: Associate tkinter messageboxes with a specific widget. For Mac OSX, make them a ‘sheet’. Patch by Mark Roseman.
- [bpo-25198](https://bugs.python.org/issue?@action=redirect&bpo=25198) [https://bugs.python.org/issue?@action=redirect&bpo=25198]: Enhance the initial html viewer now used for Idle Help. Properly indent fixed-pitch text (patch by Mark Roseman). Give code snippet a very Sphinx-like light blueish-gray background. Re-use initial width and height set by users for shell and editor. When the Table of Contents (TOC) menu is used, put the section header at the top of the screen.
- [bpo-25225](https://bugs.python.org/issue?@action=redirect&bpo=25225) [https://bugs.python.org/issue?@action=redirect&bpo=25225]: Condense and rewrite Idle doc section on text colors.
- [bpo-21995](https://bugs.python.org/issue?@action=redirect&bpo=21995) [https://bugs.python.org/issue?@action=redirect&bpo=21995]: Explain some differences between IDLE and console Python.
- [bpo-22820](https://bugs.python.org/issue?@action=redirect&bpo=22820) [https://bugs.python.org/issue?@action=redirect&bpo=22820]: Explain need for *print* when running file from Idle editor.
- [bpo-25224](https://bugs.python.org/issue?@action=redirect&bpo=25224) [https://bugs.python.org/issue?@action=redirect&bpo=25224]: Doc: augment Idle feature list and no-subprocess section.
- [bpo-25219](https://bugs.python.org/issue?@action=redirect&bpo=25219) [https://bugs.python.org/issue?@action=redirect&bpo=25219]

- @action=redirect&bpo=25219]: Update doc for Idle command line options. Some were missing and notes were not correct.
- [bpo-24861](https://bugs.python.org/issue?@action=redirect&bpo=24861) [https://bugs.python.org/issue?@action=redirect&bpo=24861]: Most of idlelib is private and subject to change. Use `idlelib.idle.*` to start Idle. See `idlelib._init_.__doc__`.
  - [bpo-25199](https://bugs.python.org/issue?@action=redirect&bpo=25199) [https://bugs.python.org/issue?@action=redirect&bpo=25199]: Idle: add synchronization comments for future maintainers.
  - [bpo-16893](https://bugs.python.org/issue?@action=redirect&bpo=16893) [https://bugs.python.org/issue?@action=redirect&bpo=16893]: Replace `help.txt` with `help.html` for Idle doc display. The new `idlelib/help.html` is `rstripped` `Doc/build/html/library/idle.html`. It looks better than `help.txt` and will better document Idle as released. The `tkinter` `html` viewer that works for this file was written by Mark Roseman. The now unused `EditorWindow.HelpDialog` class and `helt.txt` file are deprecated.
  - [bpo-24199](https://bugs.python.org/issue?@action=redirect&bpo=24199) [https://bugs.python.org/issue?@action=redirect&bpo=24199]: Deprecate unused `idlelib.idlever` with possible removal in 3.6.
  - [bpo-24790](https://bugs.python.org/issue?@action=redirect&bpo=24790) [https://bugs.python.org/issue?@action=redirect&bpo=24790]: Remove extraneous code (which also create 2 & 3 conflicts).

## Documentation

- [bpo-22558](https://bugs.python.org/issue?@action=redirect&bpo=22558) [https://bugs.python.org/issue?@action=redirect&bpo=22558]: Add remaining doc links to source code for Python-coded modules. Patch by Yoni Lavi.
- [bpo-12067](https://bugs.python.org/issue?@action=redirect&bpo=12067) [https://bugs.python.org/issue?@action=redirect&bpo=12067]: Rewrite Comparisons section in the Expressions chapter of the language reference. Some of the details of comparing mixed types were incorrect or ambiguous. `NotImplemented` is only relevant at a lower level than the Expressions chapter. Added details of comparing `range()` objects, and default behaviour and consistency suggestions for user-defined classes. Patch from Andy Maier.
- [bpo-24952](https://bugs.python.org/issue?@action=redirect&bpo=24952) [https://bugs.python.org/issue?@action=redirect&bpo=24952]: Clarify the default size argument of `stack_size()` in the “threading” and “\_thread” modules.

Patch from Mattip.

- [bpo-23725](https://bugs.python.org/issue?@action=redirect&bpo=23725) [https://bugs.python.org/issue?@action=redirect&bpo=23725]: Overhaul tempfile docs. Note deprecated status of mktemp. Patch from Zbigniew Jędrzejewski-Szmek.
- [bpo-24808](https://bugs.python.org/issue?@action=redirect&bpo=24808) [https://bugs.python.org/issue?@action=redirect&bpo=24808]: Update the types of some PyTypeObject fields. Patch by Joseph Weston.
- [bpo-22812](https://bugs.python.org/issue?@action=redirect&bpo=22812) [https://bugs.python.org/issue?@action=redirect&bpo=22812]: Fix unittest discovery examples. Patch from Pam McA’Nulty.

## Tests

- [bpo-25449](https://bugs.python.org/issue?@action=redirect&bpo=25449) [https://bugs.python.org/issue?@action=redirect&bpo=25449]: Added tests for OrderedDict subclasses.
- [bpo-25099](https://bugs.python.org/issue?@action=redirect&bpo=25099) [https://bugs.python.org/issue?@action=redirect&bpo=25099]: Make test\_compileall not fail when an entry on sys.path cannot be written to (commonly seen in administrative installs on Windows).
- [bpo-23919](https://bugs.python.org/issue?@action=redirect&bpo=23919) [https://bugs.python.org/issue?@action=redirect&bpo=23919]: Prevents assert dialogs appearing in the test suite.
- PCbuild\rt.bat now accepts an unlimited number of arguments to pass along to regrtest.py. Previously there was a limit of 9.

## Build

- [bpo-24915](https://bugs.python.org/issue?@action=redirect&bpo=24915) [https://bugs.python.org/issue?@action=redirect&bpo=24915]: Add LLVM support for PGO builds and use the test suite to generate the profile data. Initial patch by Alecsandru Patrascu of Intel.
- [bpo-24910](https://bugs.python.org/issue?@action=redirect&bpo=24910) [https://bugs.python.org/issue?@action=redirect&bpo=24910]: Windows MSIs now have unique display names.
- [bpo-24986](https://bugs.python.org/issue?@action=redirect&bpo=24986) [https://bugs.python.org/issue?@action=redirect&bpo=24986]: It is now possible to build Python on Windows without errors when external libraries are not

available.

## Windows

- [bpo-25450](https://bugs.python.org/issue?@action=redirect&bpo=25450) [https://bugs.python.org/issue?@action=redirect&bpo=25450]: Updates shortcuts to start Python in installation directory.
- [bpo-25164](https://bugs.python.org/issue?@action=redirect&bpo=25164) [https://bugs.python.org/issue?@action=redirect&bpo=25164]: Changes default all-users install directory to match per-user directory.
- [bpo-25143](https://bugs.python.org/issue?@action=redirect&bpo=25143) [https://bugs.python.org/issue?@action=redirect&bpo=25143]: Improves installer error messages for unsupported platforms.
- [bpo-25163](https://bugs.python.org/issue?@action=redirect&bpo=25163) [https://bugs.python.org/issue?@action=redirect&bpo=25163]: Display correct directory in installer when using non-default settings.
- [bpo-25361](https://bugs.python.org/issue?@action=redirect&bpo=25361) [https://bugs.python.org/issue?@action=redirect&bpo=25361]: Disables use of SSE2 instructions in Windows 32-bit build
- [bpo-25089](https://bugs.python.org/issue?@action=redirect&bpo=25089) [https://bugs.python.org/issue?@action=redirect&bpo=25089]: Adds logging to installer for case where launcher is not selected on upgrade.
- [bpo-25165](https://bugs.python.org/issue?@action=redirect&bpo=25165) [https://bugs.python.org/issue?@action=redirect&bpo=25165]: Windows uninstallation should not remove launcher if other versions remain
- [bpo-25112](https://bugs.python.org/issue?@action=redirect&bpo=25112) [https://bugs.python.org/issue?@action=redirect&bpo=25112]: py.exe launcher is missing icons
- [bpo-25102](https://bugs.python.org/issue?@action=redirect&bpo=25102) [https://bugs.python.org/issue?@action=redirect&bpo=25102]: Windows installer does not precompile for -O or -OO.
- [bpo-25081](https://bugs.python.org/issue?@action=redirect&bpo=25081) [https://bugs.python.org/issue?@action=redirect&bpo=25081]: Makes Back button in installer go back to upgrade page when upgrading.
- [bpo-25091](https://bugs.python.org/issue?@action=redirect&bpo=25091) [https://bugs.python.org/issue?@action=redirect&bpo=25091]: Increases font size of the installer.
- [bpo-25126](https://bugs.python.org/issue?@action=redirect&bpo=25126) [https://bugs.python.org/issue?@action=redirect&bpo=25126]: Clarifies that the non-web installer will download some components.
- [bpo-25213](https://bugs.python.org/issue?@action=redirect&bpo=25213) [https://bugs.python.org/issue?@action=redirect&bpo=25213]: Restores requestedExecutionLevel

to manifest to disable UAC virtualization.

- [bpo-25022](https://bugs.python.org/issue?@action=redirect&bpo=25022) [https://bugs.python.org/issue?@action=redirect&bpo=25022]: Removed very outdated PC/example\_nt/ directory.

## Tools/Demos

- [bpo-25440](https://bugs.python.org/issue?@action=redirect&bpo=25440) [https://bugs.python.org/issue?@action=redirect&bpo=25440]: Fix output of python-config – extension-suffix.

## Python 3.5.0 final

*Release date: 2015-09-13*

### Build

- [bpo-25071](https://bugs.python.org/issue?@action=redirect&bpo=25071) [https://bugs.python.org/issue?@action=redirect&bpo=25071]: Windows installer should not require TargetDir parameter when installing quietly.

## Python 3.5.0 release candidate 4

*Release date: 2015-09-09*

### Library

- [bpo-25029](https://bugs.python.org/issue?@action=redirect&bpo=25029) [https://bugs.python.org/issue?@action=redirect&bpo=25029]: Fixes MemoryError in test\_strptime.

### Build

- [bpo-25027](https://bugs.python.org/issue?@action=redirect&bpo=25027) [https://bugs.python.org/issue?@action=redirect&bpo=25027]: Reverts partial-static build options and adds vcruntime140.dll to Windows installation.

## Python 3.5.0 release candidate 3

*Release date: 2015-09-07*

## Core and Builtins

- [bpo-24305](https://bugs.python.org/issue?@action=redirect&bpo=24305) [https://bugs.python.org/issue?@action=redirect&bpo=24305]: Prevent import subsystem stack frames from being counted by the `warnings.warn(stacklevel=)` parameter.
- [bpo-24912](https://bugs.python.org/issue?@action=redirect&bpo=24912) [https://bugs.python.org/issue?@action=redirect&bpo=24912]: Prevent `__class__` assignment to immutable built-in objects.
- [bpo-24975](https://bugs.python.org/issue?@action=redirect&bpo=24975) [https://bugs.python.org/issue?@action=redirect&bpo=24975]: Fix AST compilation for [PEP 448](https://peps.python.org/pep-0448/) [https://peps.python.org/pep-0448/] syntax.

## Library

- [bpo-24917](https://bugs.python.org/issue?@action=redirect&bpo=24917) [https://bugs.python.org/issue?@action=redirect&bpo=24917]: `time.strftime()` buffer over-read.
- [bpo-24748](https://bugs.python.org/issue?@action=redirect&bpo=24748) [https://bugs.python.org/issue?@action=redirect&bpo=24748]: To resolve a compatibility problem found with `py2exe` and `pywin32`, `imp.load_dynamic()` once again ignores previously loaded modules to support Python modules replacing themselves with extension modules. Patch by Petr Viktorin.
- [bpo-24635](https://bugs.python.org/issue?@action=redirect&bpo=24635) [https://bugs.python.org/issue?@action=redirect&bpo=24635]: Fixed a bug in `typing.py` where `isinstance([], typing.Iterable)` would return `True` once, then `False` on subsequent calls.
- [bpo-24989](https://bugs.python.org/issue?@action=redirect&bpo=24989) [https://bugs.python.org/issue?@action=redirect&bpo=24989]: Fixed buffer overread in `BytesIO.readline()` if a position is set beyond size. Based on patch by John Leitch.
- [bpo-24913](https://bugs.python.org/issue?@action=redirect&bpo=24913) [https://bugs.python.org/issue?@action=redirect&bpo=24913]: Fix overrun error in `deque.index()`. Found by John Leitch and Bryce Darling.

## Python 3.5.0 release candidate 2

*Release date: 2015-08-25*

## Core and Builtins

- [bpo-24769](https://bugs.python.org/issue?@action=redirect&bpo=24769) [https://bugs.python.org/issue?@action=redirect&bpo=24769]: Interpreter now starts properly when dynamic loading is disabled. Patch by Petr Viktorin.
- [bpo-21167](https://bugs.python.org/issue?@action=redirect&bpo=21167) [https://bugs.python.org/issue?@action=redirect&bpo=21167]: NAN operations are now handled correctly when python is compiled with ICC even if -fp-model strict is not specified.
- [bpo-24492](https://bugs.python.org/issue?@action=redirect&bpo=24492) [https://bugs.python.org/issue?@action=redirect&bpo=24492]: A “package” lacking a `__name__` attribute when trying to perform a `from .. import ...` statement will trigger an `ImportError` instead of an `AttributeError`.

## Library

- [bpo-24847](https://bugs.python.org/issue?@action=redirect&bpo=24847) [https://bugs.python.org/issue?@action=redirect&bpo=24847]: Removes `vcruntime140.dll` dependency from Tcl/Tk.
- [bpo-24839](https://bugs.python.org/issue?@action=redirect&bpo=24839) [https://bugs.python.org/issue?@action=redirect&bpo=24839]: `platform._syscmd_ver` raises `DeprecationWarning`
- [bpo-24867](https://bugs.python.org/issue?@action=redirect&bpo=24867) [https://bugs.python.org/issue?@action=redirect&bpo=24867]: Fix `Task.get_stack()` for ‘async def’ coroutines

## Python 3.5.0 release candidate 1

*Release date: 2015-08-09*

## Core and Builtins

- [bpo-24667](https://bugs.python.org/issue?@action=redirect&bpo=24667) [https://bugs.python.org/issue?@action=redirect&bpo=24667]: Resize `odict` in all cases that the underlying dict resizes.

## Library

- [bpo-24824](https://bugs.python.org/issue?@action=redirect&bpo=24824) [https://bugs.python.org/issue?@action=redirect&bpo=24824]: Signatures of `codecs.encode()` and `codecs.decode()` now are compatible with `pydoc`.
- [bpo-24634](https://bugs.python.org/issue?@action=redirect&bpo=24634) [https://bugs.python.org/issue?@action=redirect&bpo=24634]: Importing `uuid` should not try to load `libc` on Windows
- [bpo-24798](https://bugs.python.org/issue?@action=redirect&bpo=24798) [https://bugs.python.org/issue?@action=redirect&bpo=24798]: `_msvccompiler.py` doesn't properly support manifests
- [bpo-4395](https://bugs.python.org/issue?@action=redirect&bpo=4395) [https://bugs.python.org/issue?@action=redirect&bpo=4395]: Better testing and documentation of binary operators. Patch by Martin Panter.
- [bpo-23973](https://bugs.python.org/issue?@action=redirect&bpo=23973) [https://bugs.python.org/issue?@action=redirect&bpo=23973]: Update `typing.py` from GitHub repo.
- [bpo-23004](https://bugs.python.org/issue?@action=redirect&bpo=23004) [https://bugs.python.org/issue?@action=redirect&bpo=23004]: `mock_open()` now reads binary data correctly when the type of `read_data` is `bytes`. Initial patch by Aaron Hill.
- [bpo-23888](https://bugs.python.org/issue?@action=redirect&bpo=23888) [https://bugs.python.org/issue?@action=redirect&bpo=23888]: Handle fractional time in cookie expiry. Patch by ssh.
- [bpo-23652](https://bugs.python.org/issue?@action=redirect&bpo=23652) [https://bugs.python.org/issue?@action=redirect&bpo=23652]: Make it possible to compile the `select` module against the `libc` headers from the Linux Standard Base, which do not include some `EPOLL` macros. Patch by Matt Frank.
- [bpo-22932](https://bugs.python.org/issue?@action=redirect&bpo=22932) [https://bugs.python.org/issue?@action=redirect&bpo=22932]: Fix `timezones` in `email.utils.formatdate`. Patch from Dmitry Shachnev.
- [bpo-23779](https://bugs.python.org/issue?@action=redirect&bpo=23779) [https://bugs.python.org/issue?@action=redirect&bpo=23779]: `imaplib` raises `TypeError` if authenticator tries to abort. Patch from Craig Holmquist.
- [bpo-23319](https://bugs.python.org/issue?@action=redirect&bpo=23319) [https://bugs.python.org/issue?@action=redirect&bpo=23319]: Fix `ctypes.BigEndianStructure`, swap correctly bytes. Patch written by Matthieu Gautier.
- [bpo-23254](https://bugs.python.org/issue?@action=redirect&bpo=23254) [https://bugs.python.org/issue?@action=redirect&bpo=23254]: Document how to close the

TCPServer listening socket. Patch from Martin Panter.

- [bpo-19450](https://bugs.python.org/issue?@action=redirect&bpo=19450) [https://bugs.python.org/issue?@action=redirect&bpo=19450]: Update Windows and OS X installer builds to use SQLite 3.8.11.
- [bpo-17527](https://bugs.python.org/issue?@action=redirect&bpo=17527) [https://bugs.python.org/issue?@action=redirect&bpo=17527]: Add PATCH to wsgiref.validator. Patch from Luca Sbardella.
- [bpo-24791](https://bugs.python.org/issue?@action=redirect&bpo=24791) [https://bugs.python.org/issue?@action=redirect&bpo=24791]: Fix grammar regression for call syntax: 'g(\*a or b)'.

## IDLE

- [bpo-23672](https://bugs.python.org/issue?@action=redirect&bpo=23672) [https://bugs.python.org/issue?@action=redirect&bpo=23672]: Allow Idle to edit and run files with astral chars in name. Patch by Mohd Sanad Zaki Rizvi.
- [bpo-24745](https://bugs.python.org/issue?@action=redirect&bpo=24745) [https://bugs.python.org/issue?@action=redirect&bpo=24745]: Idle editor default font. Switch from Courier to platform-sensitive TkFixedFont. This should not affect current customized font selections. If there is a problem, edit \$HOME/.idlerc/config-main.cfg and remove 'fontxxx' entries from [Editor Window]. Patch by Mark Roseman.
- [bpo-21192](https://bugs.python.org/issue?@action=redirect&bpo=21192) [https://bugs.python.org/issue?@action=redirect&bpo=21192]: Idle editor. When a file is run, put its name in the restart bar. Do not print false prompts. Original patch by Adnan Umer.
- [bpo-13884](https://bugs.python.org/issue?@action=redirect&bpo=13884) [https://bugs.python.org/issue?@action=redirect&bpo=13884]: Idle menus. Remove tearoff lines. Patch by Roger Serwy.

## Documentation

- [bpo-24129](https://bugs.python.org/issue?@action=redirect&bpo=24129) [https://bugs.python.org/issue?@action=redirect&bpo=24129]: Clarify the reference documentation for name resolution. This includes removing the assumption that readers will be familiar with the name resolution scheme Python used prior to the introduction of lexical scoping for function namespaces. Patch by Ivan Levkivskyi.

- [bpo-20769](https://bugs.python.org/issue?@action=redirect&bpo=20769) [https://bugs.python.org/issue?@action=redirect&bpo=20769]: Improve reload() docs. Patch by Dorian Pula.
- [bpo-23589](https://bugs.python.org/issue?@action=redirect&bpo=23589) [https://bugs.python.org/issue?@action=redirect&bpo=23589]: Remove duplicate sentence from the FAQ. Patch by Yongzhi Pan.
- [bpo-24729](https://bugs.python.org/issue?@action=redirect&bpo=24729) [https://bugs.python.org/issue?@action=redirect&bpo=24729]: Correct IO tutorial to match implementation regarding encoding parameter to open function.

## Tests

- [bpo-24751](https://bugs.python.org/issue?@action=redirect&bpo=24751) [https://bugs.python.org/issue?@action=redirect&bpo=24751]: When running regrtest with the -w command line option, a test run is no longer marked as a failure if all tests succeed when re-run.

# Python 3.5.0 beta 4

*Release date: 2015-07-26*

## Core and Builtins

- [bpo-23573](https://bugs.python.org/issue?@action=redirect&bpo=23573) [https://bugs.python.org/issue?@action=redirect&bpo=23573]: Restored optimization of bytes.rfind() and bytearray.rfind() for single-byte argument on Linux.
- [bpo-24569](https://bugs.python.org/issue?@action=redirect&bpo=24569) [https://bugs.python.org/issue?@action=redirect&bpo=24569]: Make [PEP 448](https://peps.python.org/pep-0448/) [https://peps.python.org/pep-0448/] dictionary evaluation more consistent.
- [bpo-24583](https://bugs.python.org/issue?@action=redirect&bpo=24583) [https://bugs.python.org/issue?@action=redirect&bpo=24583]: Fix crash when set is mutated while being updated.
- [bpo-24407](https://bugs.python.org/issue?@action=redirect&bpo=24407) [https://bugs.python.org/issue?@action=redirect&bpo=24407]: Fix crash when dict is mutated while being updated.
- [bpo-24619](https://bugs.python.org/issue?@action=redirect&bpo=24619) [https://bugs.python.org/issue?@action=redirect&bpo=24619]: New approach for tokenizing

async/await. As a consequence, it is now possible to have one-line 'async def foo(): await ..' functions.

- [bpo-24687](https://bugs.python.org/issue?@action=redirect&bpo=24687) [https://bugs.python.org/issue?@action=redirect&bpo=24687]: Plug reflink on SyntaxError in function parameters annotations.
- [bpo-15944](https://bugs.python.org/issue?@action=redirect&bpo=15944) [https://bugs.python.org/issue?@action=redirect&bpo=15944]: memoryview: Allow arbitrary formats when casting to bytes. Patch by Martin Panter.

## Library

- [bpo-23441](https://bugs.python.org/issue?@action=redirect&bpo=23441) [https://bugs.python.org/issue?@action=redirect&bpo=23441]: rcompleter now prints a tab character instead of displaying possible completions for an empty word. Initial patch by Martin Sekera.
- [bpo-24683](https://bugs.python.org/issue?@action=redirect&bpo=24683) [https://bugs.python.org/issue?@action=redirect&bpo=24683]: Fixed crashes in \_json functions called with arguments of inappropriate type.
- [bpo-21697](https://bugs.python.org/issue?@action=redirect&bpo=21697) [https://bugs.python.org/issue?@action=redirect&bpo=21697]: shutil.copytree() now correctly handles symbolic links that point to directories. Patch by Eduardo Seabra and Thomas Kluyver.
- [bpo-14373](https://bugs.python.org/issue?@action=redirect&bpo=14373) [https://bugs.python.org/issue?@action=redirect&bpo=14373]: Fixed segmentation fault when gc.collect() is called during constructing lru\_cache (C implementation).
- [bpo-24695](https://bugs.python.org/issue?@action=redirect&bpo=24695) [https://bugs.python.org/issue?@action=redirect&bpo=24695]: Fix a regression in traceback.print\_exception(). If exc\_traceback is None we shouldn't print a traceback header like described in the documentation.
- [bpo-24620](https://bugs.python.org/issue?@action=redirect&bpo=24620) [https://bugs.python.org/issue?@action=redirect&bpo=24620]: Random.setstate() now validates the value of state last element.
- [bpo-22485](https://bugs.python.org/issue?@action=redirect&bpo=22485) [https://bugs.python.org/issue?@action=redirect&bpo=22485]: Fixed an issue that caused **inspect.getsource** to return incorrect results on nested functions.
- [bpo-22153](https://bugs.python.org/issue?@action=redirect&bpo=22153) [https://bugs.python.org/issue?@action=redirect&bpo=22153]: Improve unittest docs. Patch from

Martin Panter and evilzero.

- [bpo-24580](https://bugs.python.org/issue?@action=redirect&bpo=24580) [https://bugs.python.org/issue?@action=redirect&bpo=24580]: Symbolic group references to open group in re patterns now are explicitly forbidden as well as numeric group references.
- [bpo-24206](https://bugs.python.org/issue?@action=redirect&bpo=24206) [https://bugs.python.org/issue?@action=redirect&bpo=24206]: Fixed `_eq_` and `_ne_` methods of inspect classes.
- [bpo-24631](https://bugs.python.org/issue?@action=redirect&bpo=24631) [https://bugs.python.org/issue?@action=redirect&bpo=24631]: Fixed regression in the `timeit` module with multiline setup.
- [bpo-18622](https://bugs.python.org/issue?@action=redirect&bpo=18622) [https://bugs.python.org/issue?@action=redirect&bpo=18622]: `unittest.mock.mock_open().reset_mock` would recurse infinitely. Patch from Nicola Palumbo and Laurent De Buyst.
- [bpo-23661](https://bugs.python.org/issue?@action=redirect&bpo=23661) [https://bugs.python.org/issue?@action=redirect&bpo=23661]: `unittest.mock` side\_effects can now be exceptions again. This was a regression vs Python 3.4. Patch from Ignacio Rossi
- [bpo-24608](https://bugs.python.org/issue?@action=redirect&bpo=24608) [https://bugs.python.org/issue?@action=redirect&bpo=24608]: `chunk.Chunk.read()` now always returns bytes, not str.
- [bpo-18684](https://bugs.python.org/issue?@action=redirect&bpo=18684) [https://bugs.python.org/issue?@action=redirect&bpo=18684]: Fixed reading out of the buffer in the re module.
- [bpo-24259](https://bugs.python.org/issue?@action=redirect&bpo=24259) [https://bugs.python.org/issue?@action=redirect&bpo=24259]: `tarfile` now raises a `ReadError` if an archive is truncated inside a data segment.
- [bpo-15014](https://bugs.python.org/issue?@action=redirect&bpo=15014) [https://bugs.python.org/issue?@action=redirect&bpo=15014]: `SMTP.auth()` and `SMTP.login()` now support RFC 4954's optional initial-response argument to the SMTP AUTH command.
- [bpo-24669](https://bugs.python.org/issue?@action=redirect&bpo=24669) [https://bugs.python.org/issue?@action=redirect&bpo=24669]: Fix `inspect.getsource()` for 'async def' functions. Patch by Kai Groner.
- [bpo-24688](https://bugs.python.org/issue?@action=redirect&bpo=24688) [https://bugs.python.org/issue?@action=redirect&bpo=24688]: `ast.get_docstring()` for 'async def' functions.

## Build

- [bpo-24603](https://bugs.python.org/issue?@action=redirect&bpo=24603) [https://bugs.python.org/issue?@action=redirect&bpo=24603]: Update Windows builds and OS X 10.5 installer to use OpenSSL 1.0.2d.

## Python 3.5.0 beta 3

*Release date: 2015-07-05*

### Core and Builtins

- [bpo-24467](https://bugs.python.org/issue?@action=redirect&bpo=24467) [https://bugs.python.org/issue?@action=redirect&bpo=24467]: Fixed possible buffer over-read in bytearray. The bytearray object now always allocates place for trailing null byte and it's buffer now is always null-terminated.
- Upgrade to Unicode 8.0.0.
- [bpo-24345](https://bugs.python.org/issue?@action=redirect&bpo=24345) [https://bugs.python.org/issue?@action=redirect&bpo=24345]: Add Py\_tp\_finalize slot for the stable ABI.
- [bpo-24400](https://bugs.python.org/issue?@action=redirect&bpo=24400) [https://bugs.python.org/issue?@action=redirect&bpo=24400]: Introduce a distinct type for [PEP 492](https://peps.python.org/pep-0492/) [https://peps.python.org/pep-0492/] coroutines; add types.CoroutineType, inspect.getcoroutinestate, inspect.getcoroutinelocals; coroutines no longer use CO\_GENERATOR flag; sys.set\_coroutine\_wrapper works only for 'async def' coroutines; inspect.iscoroutine no longer uses collections.abc.Coroutine, it's intended to test for pure 'async def' coroutines only; add new opcode: GET\_YIELD\_FROM\_ITER; fix generators wrapper used in types.coroutine to be instance of collections.abc.Generator; collections.abc.Awaitable and collections.abc.Coroutine can no longer be used to detect generator-based coroutines—use inspect.isawaitable instead.
- [bpo-24450](https://bugs.python.org/issue?@action=redirect&bpo=24450) [https://bugs.python.org/issue?@action=redirect&bpo=24450]: Add gi\_yieldfrom to generators and cr\_await to coroutines. Contributed by Benno Leslie and Yury Selivanov.
- [bpo-19235](https://bugs.python.org/issue?@action=redirect&bpo=19235) [https://bugs.python.org/issue?@action=redirect&bpo=19235]: Add new RecursionError

exception. Patch by Georg Brandl.

## Library

- [bpo-21750](https://bugs.python.org/issue?@action=redirect&bpo=21750) [https://bugs.python.org/issue?@action=redirect&bpo=21750]: `mock_open.read_data` can now be read from each instance, as it could in Python 3.3.
- [bpo-24552](https://bugs.python.org/issue?@action=redirect&bpo=24552) [https://bugs.python.org/issue?@action=redirect&bpo=24552]: Fix use after free in an error case of the `_pickle` module.
- [bpo-24514](https://bugs.python.org/issue?@action=redirect&bpo=24514) [https://bugs.python.org/issue?@action=redirect&bpo=24514]: `tarfile` now tolerates number fields consisting of only whitespace.
- [bpo-19176](https://bugs.python.org/issue?@action=redirect&bpo=19176) [https://bugs.python.org/issue?@action=redirect&bpo=19176]: Fixed `doctype()` related bugs in C implementation of `ElementTree`. A deprecation warning no longer issued by `XMLParser` subclass with default `doctype()` method. Direct call of `doctype()` now issues a warning. Parser's `doctype()` now is not called if target's `doctype()` is called. Based on patch by Martin Panter.
- [bpo-20387](https://bugs.python.org/issue?@action=redirect&bpo=20387) [https://bugs.python.org/issue?@action=redirect&bpo=20387]: Restore semantic round-trip correctness in `tokenize/untokenize` for tab-indented blocks.
- [bpo-24456](https://bugs.python.org/issue?@action=redirect&bpo=24456) [https://bugs.python.org/issue?@action=redirect&bpo=24456]: Fixed possible buffer over-read in `adpcm2lin()` and `lin2adpcm()` functions of the `audioop` module.
- [bpo-24336](https://bugs.python.org/issue?@action=redirect&bpo=24336) [https://bugs.python.org/issue?@action=redirect&bpo=24336]: The `contextmanager` decorator now works with functions with keyword arguments called “func” and “self”. Patch by Martin Panter.
- [bpo-24522](https://bugs.python.org/issue?@action=redirect&bpo=24522) [https://bugs.python.org/issue?@action=redirect&bpo=24522]: Fix possible integer overflow in `json accelerator` module.
- [bpo-24489](https://bugs.python.org/issue?@action=redirect&bpo=24489) [https://bugs.python.org/issue?@action=redirect&bpo=24489]: ensure a previously set C `errno` doesn't disturb `cmath.polar()`.
- [bpo-24408](https://bugs.python.org/issue?@action=redirect&bpo=24408) [https://bugs.python.org/issue?@action=redirect&bpo=24408]: Fixed `AttributeError` in `measure()` and `metrics()` methods of `tkinter.Font`.

- [bpo-14373](https://bugs.python.org/issue?@action=redirect&bpo=14373) [https://bugs.python.org/issue?@action=redirect&bpo=14373]: C implementation of `functools.lru_cache()` now can be used with methods.
- [bpo-24347](https://bugs.python.org/issue?@action=redirect&bpo=24347) [https://bugs.python.org/issue?@action=redirect&bpo=24347]: Set `KeyError` if `PyDict_GetItemWithError` returns `NULL`.
- [bpo-24348](https://bugs.python.org/issue?@action=redirect&bpo=24348) [https://bugs.python.org/issue?@action=redirect&bpo=24348]: Drop superfluous `incrf/decref`.
- [bpo-24359](https://bugs.python.org/issue?@action=redirect&bpo=24359) [https://bugs.python.org/issue?@action=redirect&bpo=24359]: Check for changed `OrderedDict` size during iteration.
- [bpo-24368](https://bugs.python.org/issue?@action=redirect&bpo=24368) [https://bugs.python.org/issue?@action=redirect&bpo=24368]: Support keyword arguments in `OrderedDict` methods.
- [bpo-24362](https://bugs.python.org/issue?@action=redirect&bpo=24362) [https://bugs.python.org/issue?@action=redirect&bpo=24362]: Simplify the C `OrderedDict` fast nodes resize logic.
- [bpo-24377](https://bugs.python.org/issue?@action=redirect&bpo=24377) [https://bugs.python.org/issue?@action=redirect&bpo=24377]: Fix a ref leak in `OrderedDict.__repr__`.
- [bpo-24369](https://bugs.python.org/issue?@action=redirect&bpo=24369) [https://bugs.python.org/issue?@action=redirect&bpo=24369]: Defend against key-changes during iteration.

## Tests

- [bpo-24373](https://bugs.python.org/issue?@action=redirect&bpo=24373) [https://bugs.python.org/issue?@action=redirect&bpo=24373]: `_testmultiphase` and `xxlimited` now use `tp_traverse` and `tp_finalize` to avoid reference leaks encountered when combining `tp_dealloc` with `PyType_FromSpec` (see [bpo-16690](https://bugs.python.org/issue?@action=redirect&bpo=16690) [https://bugs.python.org/issue?@action=redirect&bpo=16690] for details)

## Documentation

- [bpo-24458](https://bugs.python.org/issue?@action=redirect&bpo=24458) [https://bugs.python.org/issue?@action=redirect&bpo=24458]: Update documentation to cover multi-phase initialization for extension modules (PEP 489). Patch by Petr Viktorin.
- [bpo-24351](https://bugs.python.org/issue?@action=redirect&bpo=24351) [https://bugs.python.org/issue?@action=redirect&bpo=24351]

@action=redirect&bpo=24351]: Clarify what is meant by “identifier” in the context of string.Template instances.

## Build

- [bpo-24432](https://bugs.python.org/issue?@action=redirect&bpo=24432) [https://bugs.python.org/issue?@action=redirect&bpo=24432]: Update Windows builds and OS X 10.5 installer to use OpenSSL 1.0.2c.

## Python 3.5.0 beta 2

*Release date: 2015-05-31*

### Core and Builtins

- [bpo-24284](https://bugs.python.org/issue?@action=redirect&bpo=24284) [https://bugs.python.org/issue?@action=redirect&bpo=24284]: The startswith and endswith methods of the str class no longer return True when finding the empty string and the indexes are completely out of range.
- [bpo-24115](https://bugs.python.org/issue?@action=redirect&bpo=24115) [https://bugs.python.org/issue?@action=redirect&bpo=24115]: Update uses of PyObject\_IsTrue(), PyObject\_Not(), PyObject\_IsInstance(), PyObject\_RichCompareBool() and \_PyDict\_Contains() to check for and handle errors correctly.
- [bpo-24328](https://bugs.python.org/issue?@action=redirect&bpo=24328) [https://bugs.python.org/issue?@action=redirect&bpo=24328]: Fix importing one character extension modules.
- [bpo-11205](https://bugs.python.org/issue?@action=redirect&bpo=11205) [https://bugs.python.org/issue?@action=redirect&bpo=11205]: In dictionary displays, evaluate the key before the value.
- [bpo-24285](https://bugs.python.org/issue?@action=redirect&bpo=24285) [https://bugs.python.org/issue?@action=redirect&bpo=24285]: Fixed regression that prevented importing extension modules from inside packages. Patch by Petr Viktorin.

## Library

- [bpo-23247](https://bugs.python.org/issue?@action=redirect&bpo=23247) [https://bugs.python.org/issue?@action=redirect&bpo=23247]: Fix a crash in the

StreamWriter.reset() of CJK codecs.

- [bpo-24270](https://bugs.python.org/issue?@action=redirect&bpo=24270) [https://bugs.python.org/issue?@action=redirect&bpo=24270]: Add `math.isclose()` and `cmath.isclose()` functions as per [PEP 485](https://peps.python.org/pep-0485/) [https://peps.python.org/pep-0485/]. Contributed by Chris Barker and Tal Einat.
- [bpo-5633](https://bugs.python.org/issue?@action=redirect&bpo=5633) [https://bugs.python.org/issue?@action=redirect&bpo=5633]: Fixed `timeit` when the statement is a string and the setup is `not`.
- [bpo-24326](https://bugs.python.org/issue?@action=redirect&bpo=24326) [https://bugs.python.org/issue?@action=redirect&bpo=24326]: Fixed `audioop.ratecv()` with non-default `weightB` argument. Original patch by David Moore.
- [bpo-16991](https://bugs.python.org/issue?@action=redirect&bpo=16991) [https://bugs.python.org/issue?@action=redirect&bpo=16991]: Add a C implementation of `OrderedDict`.
- [bpo-23934](https://bugs.python.org/issue?@action=redirect&bpo=23934) [https://bugs.python.org/issue?@action=redirect&bpo=23934]: Fix `inspect.signature` to fail correctly for builtin types lacking signature information. Initial patch by James Powell.

## Python 3.5.0 beta 1

*Release date: 2015-05-24*

### Core and Builtins

- [bpo-24276](https://bugs.python.org/issue?@action=redirect&bpo=24276) [https://bugs.python.org/issue?@action=redirect&bpo=24276]: Fixed optimization of property descriptor getter.
- [bpo-24268](https://bugs.python.org/issue?@action=redirect&bpo=24268) [https://bugs.python.org/issue?@action=redirect&bpo=24268]: [PEP 489](https://peps.python.org/pep-489/): Multi-phase extension module initialization. Patch by Petr Viktorin.
- [bpo-23955](https://bugs.python.org/issue?@action=redirect&bpo=23955) [https://bugs.python.org/issue?@action=redirect&bpo=23955]: Add `pyvenv.cfg` option to suppress registry/environment lookup for generating `sys.path` on Windows.
- [bpo-24257](https://bugs.python.org/issue?@action=redirect&bpo=24257) [https://bugs.python.org/issue?@action=redirect&bpo=24257]: Fixed system error in the comparison of faked types.`SimpleNamespace`.
- [bpo-22939](https://bugs.python.org/issue?@action=redirect&bpo=22939) [https://bugs.python.org/issue?@action=redirect&bpo=22939]

@action=redirect&bpo=22939]: Fixed integer overflow in iterator object. Patch by Clement Rouault.

- [bpo-23985](https://bugs.python.org/issue?@action=redirect&bpo=23985) [https://bugs.python.org/issue?@action=redirect&bpo=23985]: Fix a possible buffer overrun when deleting a slice from the front of a bytearray and then appending some other bytes data.
- [bpo-24102](https://bugs.python.org/issue?@action=redirect&bpo=24102) [https://bugs.python.org/issue?@action=redirect&bpo=24102]: Fixed exception type checking in standard error handlers.
- [bpo-15027](https://bugs.python.org/issue?@action=redirect&bpo=15027) [https://bugs.python.org/issue?@action=redirect&bpo=15027]: The UTF-32 encoder is now 3x to 7x faster.
- [bpo-23290](https://bugs.python.org/issue?@action=redirect&bpo=23290) [https://bugs.python.org/issue?@action=redirect&bpo=23290]: Optimize set\_merge() for cases where the target is empty. (Contributed by Serhiy Storchaka.)
- [bpo-2292](https://bugs.python.org/issue?@action=redirect&bpo=2292) [https://bugs.python.org/issue?@action=redirect&bpo=2292]: PEP 448: Additional Unpacking Generalizations.
- [bpo-24096](https://bugs.python.org/issue?@action=redirect&bpo=24096) [https://bugs.python.org/issue?@action=redirect&bpo=24096]: Make warnings.warn\_explicit more robust against mutation of the warnings.filters list.
- [bpo-23996](https://bugs.python.org/issue?@action=redirect&bpo=23996) [https://bugs.python.org/issue?@action=redirect&bpo=23996]: Avoid a crash when a delegated generator raises an unnormalized StopIteration exception. Patch by Stefan Behnel.
- [bpo-23910](https://bugs.python.org/issue?@action=redirect&bpo=23910) [https://bugs.python.org/issue?@action=redirect&bpo=23910]: Optimize property() getter calls. Patch by Joe Jevnik.
- [bpo-23911](https://bugs.python.org/issue?@action=redirect&bpo=23911) [https://bugs.python.org/issue?@action=redirect&bpo=23911]: Move path-based importlib bootstrap code to a separate frozen module.
- [bpo-24192](https://bugs.python.org/issue?@action=redirect&bpo=24192) [https://bugs.python.org/issue?@action=redirect&bpo=24192]: Fix namespace package imports.
- [bpo-24022](https://bugs.python.org/issue?@action=redirect&bpo=24022) [https://bugs.python.org/issue?@action=redirect&bpo=24022]: Fix tokenizer crash when processing undecodable source code.
- [bpo-9951](https://bugs.python.org/issue?@action=redirect&bpo=9951) [https://bugs.python.org/issue?@action=redirect&bpo=9951]: Added a hex() method to bytes, bytearray, and memoryview.
- [bpo-22906](https://bugs.python.org/issue?@action=redirect&bpo=22906) [https://bugs.python.org/issue?@action=redirect&bpo=22906]: PEP 479: Change StopIteration handling inside generators.

- [bpo-24017](https://bugs.python.org/issue?@action=redirect&bpo=24017) [https://bugs.python.org/issue?@action=redirect&bpo=24017]: PEP 492: Coroutines with `async` and `await` syntax.

## Library

- [bpo-14373](https://bugs.python.org/issue?@action=redirect&bpo=14373) [https://bugs.python.org/issue?@action=redirect&bpo=14373]: Added C implementation of `functools.lru_cache()`. Based on patches by Matt Joiner and Alexey Kachayev.
- [bpo-24230](https://bugs.python.org/issue?@action=redirect&bpo=24230) [https://bugs.python.org/issue?@action=redirect&bpo=24230]: The `tempfile` module now accepts bytes for `prefix`, `suffix` and `dir` parameters and returns bytes in such situations (matching the `os` module APIs).
- [bpo-22189](https://bugs.python.org/issue?@action=redirect&bpo=22189) [https://bugs.python.org/issue?@action=redirect&bpo=22189]: `collections.UserString` now supports `_getnewargs_()`, `_rmod_()`, `casefold()`, `format_map()`, `isprintable()`, and `maketrans()`. Patch by Joe Jevnik.
- [bpo-24244](https://bugs.python.org/issue?@action=redirect&bpo=24244) [https://bugs.python.org/issue?@action=redirect&bpo=24244]: Prevents termination when an invalid format string is encountered on Windows in `strftime`.
- [bpo-23973](https://bugs.python.org/issue?@action=redirect&bpo=23973) [https://bugs.python.org/issue?@action=redirect&bpo=23973]: PEP 484: Add the typing module.
- [bpo-23086](https://bugs.python.org/issue?@action=redirect&bpo=23086) [https://bugs.python.org/issue?@action=redirect&bpo=23086]: The `collections.abc.Sequence()` abstract base class added *start* and *stop* parameters to the `index()` mixin. Patch by Devin Jeanpierre.
- [bpo-20035](https://bugs.python.org/issue?@action=redirect&bpo=20035) [https://bugs.python.org/issue?@action=redirect&bpo=20035]: Replaced the `tkinter._fix` module used for setting up the Tcl/Tk environment on Windows with a private function in the `_tkinter` module that makes no permanent changes to the environment.
- [bpo-24257](https://bugs.python.org/issue?@action=redirect&bpo=24257) [https://bugs.python.org/issue?@action=redirect&bpo=24257]: Fixed segmentation fault in `sqlite3.Row` constructor with faked cursor type.
- [bpo-15836](https://bugs.python.org/issue?@action=redirect&bpo=15836) [https://bugs.python.org/issue?@action=redirect&bpo=15836]: `assertRaises()`, `assertRaisesRegex()`, `assertWarns()` and `assertWarnsRegex()` assertions now check the type of the first argument to

prevent possible user error. Based on patch by Daniel Wagner-Hall.

- [bpo-9858](https://bugs.python.org/issue?@action=redirect&bpo=9858) [https://bugs.python.org/issue?@action=redirect&bpo=9858]: Add missing method stubs to `_io.RawIOBase`. Patch by Laura Rupprecht.
- [bpo-22955](https://bugs.python.org/issue?@action=redirect&bpo=22955) [https://bugs.python.org/issue?@action=redirect&bpo=22955]: `attrgetter`, `itemgetter` and `methodcaller` objects in the `operator` module now support pickling. Added readable and evaluable repr for these objects. Based on patch by Josh Rosenberg.
- [bpo-22107](https://bugs.python.org/issue?@action=redirect&bpo=22107) [https://bugs.python.org/issue?@action=redirect&bpo=22107]: `tempfile.gettempdir()` and `tempfile.mkdtemp()` now try again when a directory with the chosen name already exists on Windows as well as on Unix. `tempfile.mkstemp()` now fails early if parent directory is not valid (not exists or is a file) on Windows.
- [bpo-23780](https://bugs.python.org/issue?@action=redirect&bpo=23780) [https://bugs.python.org/issue?@action=redirect&bpo=23780]: Improved error message in `os.path.join()` with single argument.
- [bpo-6598](https://bugs.python.org/issue?@action=redirect&bpo=6598) [https://bugs.python.org/issue?@action=redirect&bpo=6598]: Increased time precision and random number range in `email.utils.make_msgid()` to strengthen the uniqueness of the message ID.
- [bpo-24091](https://bugs.python.org/issue?@action=redirect&bpo=24091) [https://bugs.python.org/issue?@action=redirect&bpo=24091]: Fixed various crashes in corner cases in C implementation of `ElementTree`.
- [bpo-21931](https://bugs.python.org/issue?@action=redirect&bpo=21931) [https://bugs.python.org/issue?@action=redirect&bpo=21931]: `msilib.FCICreate()` now raises `TypeError` in the case of a bad argument instead of a `ValueError` with a bogus FCI error number. Patch by Jeffrey Armstrong.
- [bpo-13866](https://bugs.python.org/issue?@action=redirect&bpo=13866) [https://bugs.python.org/issue?@action=redirect&bpo=13866]: `quote_via` argument added to `urllib.parse.urlencode`.
- [bpo-20098](https://bugs.python.org/issue?@action=redirect&bpo=20098) [https://bugs.python.org/issue?@action=redirect&bpo=20098]: New `mangle_from` policy option for email, default `True` for `compat32`, but `False` for all other policies.
- [bpo-24211](https://bugs.python.org/issue?@action=redirect&bpo=24211) [https://bugs.python.org/issue?@action=redirect&bpo=24211]: The email library now supports

RFC 6532: it can generate headers using utf-8 instead of encoded words.

- [bpo-16314](https://bugs.python.org/issue?@action=redirect&bpo=16314) [https://bugs.python.org/issue?@action=redirect&bpo=16314]: Added support for the LZMA compression in distutils.
- [bpo-21804](https://bugs.python.org/issue?@action=redirect&bpo=21804) [https://bugs.python.org/issue?@action=redirect&bpo=21804]: poplib now supports RFC 6856 (UTF8).
- [bpo-18682](https://bugs.python.org/issue?@action=redirect&bpo=18682) [https://bugs.python.org/issue?@action=redirect&bpo=18682]: Optimized pprint functions for builtin scalar types.
- [bpo-22027](https://bugs.python.org/issue?@action=redirect&bpo=22027) [https://bugs.python.org/issue?@action=redirect&bpo=22027]: smtplib now supports RFC 6531 (SMTPUTF8).
- [bpo-23488](https://bugs.python.org/issue?@action=redirect&bpo=23488) [https://bugs.python.org/issue?@action=redirect&bpo=23488]: Random generator objects now consume 2x less memory on 64-bit.
- [bpo-1322](https://bugs.python.org/issue?@action=redirect&bpo=1322) [https://bugs.python.org/issue?@action=redirect&bpo=1322]: platform.dist() and platform.linux\_distribution() functions are now deprecated. Initial patch by Vajrasky Kok.
- [bpo-22486](https://bugs.python.org/issue?@action=redirect&bpo=22486) [https://bugs.python.org/issue?@action=redirect&bpo=22486]: Added the math.gcd() function. The fractions.gcd() function now is deprecated. Based on patch by Mark Dickinson.
- [bpo-24064](https://bugs.python.org/issue?@action=redirect&bpo=24064) [https://bugs.python.org/issue?@action=redirect&bpo=24064]: Property() docstrings are now writeable. (Patch by Berker Peksag.)
- [bpo-22681](https://bugs.python.org/issue?@action=redirect&bpo=22681) [https://bugs.python.org/issue?@action=redirect&bpo=22681]: Added support for the koi8\_t encoding.
- [bpo-22682](https://bugs.python.org/issue?@action=redirect&bpo=22682) [https://bugs.python.org/issue?@action=redirect&bpo=22682]: Added support for the kz1048 encoding.
- [bpo-23796](https://bugs.python.org/issue?@action=redirect&bpo=23796) [https://bugs.python.org/issue?@action=redirect&bpo=23796]: peek and read1 methods of BufferedReader now raise ValueError if they called on a closed object. Patch by John Hergenroeder.
- [bpo-21795](https://bugs.python.org/issue?@action=redirect&bpo=21795) [https://bugs.python.org/issue?@action=redirect&bpo=21795]: smtpd now supports the 8BITMIME extension whenever the new *decode\_data*

constructor argument is set to False.

- [bpo-24155](https://bugs.python.org/issue?@action=redirect&bpo=24155) [https://bugs.python.org/issue?@action=redirect&bpo=24155]: optimize `heapq.heapify()` for better cache performance when heapifying large lists.
- [bpo-21800](https://bugs.python.org/issue?@action=redirect&bpo=21800) [https://bugs.python.org/issue?@action=redirect&bpo=21800]: `imaplib` now supports RFC 5161 (enable), RFC 6855 (utf8/internationalized email) and automatically encodes non-ASCII usernames and passwords to UTF8.
- [bpo-20274](https://bugs.python.org/issue?@action=redirect&bpo=20274) [https://bugs.python.org/issue?@action=redirect&bpo=20274]: When calling a `_sqlite.Connection`, it now complains if passed any keyword arguments. Previously it silently ignored them.
- [bpo-20274](https://bugs.python.org/issue?@action=redirect&bpo=20274) [https://bugs.python.org/issue?@action=redirect&bpo=20274]: Remove ignored and erroneous “kwargs” parameters from three `METH_VARARGS` methods on `_sqlite.Connection`.
- [bpo-24134](https://bugs.python.org/issue?@action=redirect&bpo=24134) [https://bugs.python.org/issue?@action=redirect&bpo=24134]: `assertRaises()`, `assertRaisesRegex()`, `assertWarns()` and `assertWarnsRegex()` checks now emits a deprecation warning when callable is `None` or keyword arguments except `msg` is passed in the context manager mode.
- [bpo-24018](https://bugs.python.org/issue?@action=redirect&bpo=24018) [https://bugs.python.org/issue?@action=redirect&bpo=24018]: Add a `collections.abc.Generator` abstract base class. Contributed by Stefan Behnel.
- [bpo-23880](https://bugs.python.org/issue?@action=redirect&bpo=23880) [https://bugs.python.org/issue?@action=redirect&bpo=23880]: Tkinter’s `getint()` and `getdouble()` now support `Tcl_Obj`. Tkinter’s `getdouble()` now supports any numbers (in particular `int`).
- [bpo-22619](https://bugs.python.org/issue?@action=redirect&bpo=22619) [https://bugs.python.org/issue?@action=redirect&bpo=22619]: Added negative limit support in the `traceback` module. Based on patch by Dmitry Kazakov.
- [bpo-24094](https://bugs.python.org/issue?@action=redirect&bpo=24094) [https://bugs.python.org/issue?@action=redirect&bpo=24094]: Fix possible crash in `json.encode` with poorly behaved dict subclasses.
- [bpo-9246](https://bugs.python.org/issue?@action=redirect&bpo=9246) [https://bugs.python.org/issue?@action=redirect&bpo=9246]: On POSIX, `os.getcwd()` now supports paths longer than 1025 bytes. Patch written by William Orr.
- [bpo-17445](https://bugs.python.org/issue?@action=redirect&bpo=17445) [https://bugs.python.org/issue?@action=redirect&bpo=17445]

- @action=redirect&bpo=17445]: add `difflib.diff_bytes()` to support comparison of byte strings (fixes a regression from Python 2).
- [bpo-23917](https://bugs.python.org/issue?@action=redirect&bpo=23917) [https://bugs.python.org/issue?@action=redirect&bpo=23917]: Fall back to sequential compilation when `ProcessPoolExecutor` doesn't exist. Patch by Claudiu Popa.
  - [bpo-23008](https://bugs.python.org/issue?@action=redirect&bpo=23008) [https://bugs.python.org/issue?@action=redirect&bpo=23008]: Fixed resolving attributes with boolean value is `False` in `pydoc`.
  - Fix `asyncio` issue 235: `LifoQueue` and `PriorityQueue`'s `put` didn't increment unfinished tasks (this bug was introduced when `JoinableQueue` was merged with `Queue`).
  - [bpo-23908](https://bugs.python.org/issue?@action=redirect&bpo=23908) [https://bugs.python.org/issue?@action=redirect&bpo=23908]: `os` functions now reject paths with embedded null character on Windows instead of silently truncating them.
  - [bpo-23728](https://bugs.python.org/issue?@action=redirect&bpo=23728) [https://bugs.python.org/issue?@action=redirect&bpo=23728]: `binascii.crc_hqx()` could return an integer outside of the range `0-0xffff` for empty data.
  - [bpo-23887](https://bugs.python.org/issue?@action=redirect&bpo=23887) [https://bugs.python.org/issue?@action=redirect&bpo=23887]: `urllib.error.HTTPError` now has a proper `repr()` representation. Patch by Berker Peksag.
  - `asyncio`: New event loop APIs: `set_task_factory()` and `get_task_factory()`.
  - `asyncio`: `async()` function is deprecated in favour of `ensure_future()`.
  - [bpo-24178](https://bugs.python.org/issue?@action=redirect&bpo=24178) [https://bugs.python.org/issue?@action=redirect&bpo=24178]: `asyncio.Lock`, `Condition`, `Semaphore`, and `BoundedSemaphore` support new 'async with' syntax. Contributed by Yuri Selivanov.
  - [bpo-24179](https://bugs.python.org/issue?@action=redirect&bpo=24179) [https://bugs.python.org/issue?@action=redirect&bpo=24179]: Support 'async for' for `asyncio.StreamReader`. Contributed by Yuri Selivanov.
  - [bpo-24184](https://bugs.python.org/issue?@action=redirect&bpo=24184) [https://bugs.python.org/issue?@action=redirect&bpo=24184]: Add `AsyncIterator` and `AsyncIterable` ABCs to `collections.abc`. Contributed by Yuri Selivanov.
  - [bpo-22547](https://bugs.python.org/issue?@action=redirect&bpo=22547) [https://bugs.python.org/issue?@action=redirect&bpo=22547]: Implement informative `__repr__` for `inspect.BoundArguments`. Contributed by Yuri Selivanov.

- [bpo-24190](https://bugs.python.org/issue?@action=redirect&bpo=24190) [https://bugs.python.org/issue?@action=redirect&bpo=24190]: Implement `inspect.BoundArgument.apply_defaults()` method. Contributed by Yury Selivanov.
- [bpo-20691](https://bugs.python.org/issue?@action=redirect&bpo=20691) [https://bugs.python.org/issue?@action=redirect&bpo=20691]: Add ‘follow\_wrapped’ argument to `inspect.Signature.from_callable()` and `inspect.signature()`. Contributed by Yury Selivanov.
- [bpo-24248](https://bugs.python.org/issue?@action=redirect&bpo=24248) [https://bugs.python.org/issue?@action=redirect&bpo=24248]: Deprecate `inspect.Signature.from_function()` and `inspect.Signature.from_builtin()`.
- [bpo-23898](https://bugs.python.org/issue?@action=redirect&bpo=23898) [https://bugs.python.org/issue?@action=redirect&bpo=23898]: Fix `inspect.classify_class_attrs()` to support attributes with overloaded `__eq__` and `__bool__`. Patch by Mike Bayer.
- [bpo-24298](https://bugs.python.org/issue?@action=redirect&bpo=24298) [https://bugs.python.org/issue?@action=redirect&bpo=24298]: Fix `inspect.signature()` to correctly unwrap wrappers around bound methods.

## IDLE

- [bpo-23184](https://bugs.python.org/issue?@action=redirect&bpo=23184) [https://bugs.python.org/issue?@action=redirect&bpo=23184]: remove unused names and imports in `idlelib`. Initial patch by Al Sweigart.

## Tests

- [bpo-21520](https://bugs.python.org/issue?@action=redirect&bpo=21520) [https://bugs.python.org/issue?@action=redirect&bpo=21520]: `test_zipfile` no longer fails if the word ‘bad’ appears anywhere in the name of the current directory.
- [bpo-9517](https://bugs.python.org/issue?@action=redirect&bpo=9517) [https://bugs.python.org/issue?@action=redirect&bpo=9517]: Move `script_helper` into the support package. Patch by Christie Wilson.

## Documentation

- [bpo-22155](https://bugs.python.org/issue?@action=redirect&bpo=22155) [https://bugs.python.org/issue?@action=redirect&bpo=22155]: Add File Handlers subsection with

createfilehandler to tkinter doc. Remove obsolete example from FAQ. Patch by Martin Panter.

- [bpo-24029](https://bugs.python.org/issue?@action=redirect&bpo=24029) [https://bugs.python.org/issue?@action=redirect&bpo=24029]: Document the name binding behavior for submodule imports.
- [bpo-24077](https://bugs.python.org/issue?@action=redirect&bpo=24077) [https://bugs.python.org/issue?@action=redirect&bpo=24077]: Fix typo in man page for -I command option: -s, not -S

## Tools/Demos

- [bpo-24000](https://bugs.python.org/issue?@action=redirect&bpo=24000) [https://bugs.python.org/issue?@action=redirect&bpo=24000]: Improved Argument Clinic's mapping of converters to legacy "format units". Updated the documentation to match.
- [bpo-24001](https://bugs.python.org/issue?@action=redirect&bpo=24001) [https://bugs.python.org/issue?@action=redirect&bpo=24001]: Argument Clinic converters now use accept = {type} instead of types = {'type'} to specify the types the converter accepts.
- [bpo-23330](https://bugs.python.org/issue?@action=redirect&bpo=23330) [https://bugs.python.org/issue?@action=redirect&bpo=23330]: h2py now supports arbitrary filenames in #include.
- [bpo-24031](https://bugs.python.org/issue?@action=redirect&bpo=24031) [https://bugs.python.org/issue?@action=redirect&bpo=24031]: make patchcheck now supports git checkouts, too.

## Python 3.5.0 alpha 4

*Release date: 2015-04-19*

## Core and Builtins

- [bpo-22980](https://bugs.python.org/issue?@action=redirect&bpo=22980) [https://bugs.python.org/issue?@action=redirect&bpo=22980]: Under Linux, GNU/KFreeBSD and the Hurd, C extensions now include the architecture triplet in the extension name, to make it easy to test builds for different ABIs in the same working tree. Under OS X, the extension name now includes [PEP 3149](https://peps.python.org/pep-3149/) [https://peps.python.org/pep-3149/] - style information.

- [bpo-22631](https://bugs.python.org/issue?@action=redirect&bpo=22631) [https://bugs.python.org/issue?@action=redirect&bpo=22631]: Added Linux-specific socket constant `CAN_RAW_FD_FRAMES`. Patch courtesy of Joe Jevnik.
- [bpo-23731](https://bugs.python.org/issue?@action=redirect&bpo=23731) [https://bugs.python.org/issue?@action=redirect&bpo=23731]: Implement [PEP 488](https://peps.python.org/pep-0488/) [https://peps.python.org/pep-0488/]: removal of `.pyo` files.
- [bpo-23726](https://bugs.python.org/issue?@action=redirect&bpo=23726) [https://bugs.python.org/issue?@action=redirect&bpo=23726]: Don't enable GC for user subclasses of non-GC types that don't add any new fields. Patch by Eugene Toder.
- [bpo-23309](https://bugs.python.org/issue?@action=redirect&bpo=23309) [https://bugs.python.org/issue?@action=redirect&bpo=23309]: Avoid a deadlock at shutdown if a daemon thread is aborted while it is holding a lock to a buffered I/O object, and the main thread tries to use the same I/O object (typically `stdout` or `stderr`). A fatal error is emitted instead.
- [bpo-22977](https://bugs.python.org/issue?@action=redirect&bpo=22977) [https://bugs.python.org/issue?@action=redirect&bpo=22977]: Fixed formatting Windows error messages on Wine. Patch by Martin Panter.
- [bpo-23466](https://bugs.python.org/issue?@action=redirect&bpo=23466) [https://bugs.python.org/issue?@action=redirect&bpo=23466]: `%c`, `%o`, `%x`, and `%X` in bytes formatting now raise `TypeError` on non-integer input.
- [bpo-24044](https://bugs.python.org/issue?@action=redirect&bpo=24044) [https://bugs.python.org/issue?@action=redirect&bpo=24044]: Fix possible null pointer dereference in `list.sort` in out of memory conditions.
- [bpo-21354](https://bugs.python.org/issue?@action=redirect&bpo=21354) [https://bugs.python.org/issue?@action=redirect&bpo=21354]: `PyCFunction_New` function is exposed by python DLL again.

## Library

- [bpo-23840](https://bugs.python.org/issue?@action=redirect&bpo=23840) [https://bugs.python.org/issue?@action=redirect&bpo=23840]: `tokenize.open()` now closes the temporary binary file on error to fix a resource warning.
- [bpo-16914](https://bugs.python.org/issue?@action=redirect&bpo=16914) [https://bugs.python.org/issue?@action=redirect&bpo=16914]: new `debuglevel 2` in `smtplib` adds timestamps to debug output.
- [bpo-7159](https://bugs.python.org/issue?@action=redirect&bpo=7159) [https://bugs.python.org/issue?@action=redirect&bpo=7159]: `urllib.request` now supports sending auth credentials

automatically after the first 401. This enhancement is a superset of the enhancement from [bpo-19494](https://bugs.python.org/issue?@action=redirect&bpo=19494) [https://bugs.python.org/issue?@action=redirect&bpo=19494] and supersedes that change.

- [bpo-23703](https://bugs.python.org/issue?@action=redirect&bpo=23703) [https://bugs.python.org/issue?@action=redirect&bpo=23703]: Fix a regression in `urljoin()` introduced in 901e4e52b20a. Patch by Demian Brecht.
- [bpo-4254](https://bugs.python.org/issue?@action=redirect&bpo=4254) [https://bugs.python.org/issue?@action=redirect&bpo=4254]: Adds `_curses.update_lines_cols()`. Patch by Arnon Yaari
- [bpo-19933](https://bugs.python.org/issue?@action=redirect&bpo=19933) [https://bugs.python.org/issue?@action=redirect&bpo=19933]: Provide default argument for `ndigits` in `round`. Patch by Vajrasky Kok.
- [bpo-23193](https://bugs.python.org/issue?@action=redirect&bpo=23193) [https://bugs.python.org/issue?@action=redirect&bpo=23193]: Add a `numeric_owner` parameter to `tarfile.TarFile.extract` and `tarfile.TarFile.extractall`. Patch by Michael Vogt and Eric Smith.
- [bpo-23342](https://bugs.python.org/issue?@action=redirect&bpo=23342) [https://bugs.python.org/issue?@action=redirect&bpo=23342]: Add a `subprocess.run()` function than returns a `CalledProcess` instance for a more consistent API than the existing `call*` functions.
- [bpo-21217](https://bugs.python.org/issue?@action=redirect&bpo=21217) [https://bugs.python.org/issue?@action=redirect&bpo=21217]: `inspect.getsourcelines()` now tries to compute the start and end lines from the code object, fixing an issue when a lambda function is used as decorator argument. Patch by Thomas Ballinger and Allison Kaptur.
- [bpo-24521](https://bugs.python.org/issue?@action=redirect&bpo=24521) [https://bugs.python.org/issue?@action=redirect&bpo=24521]: Fix possible integer overflows in the pickle module.
- [bpo-22931](https://bugs.python.org/issue?@action=redirect&bpo=22931) [https://bugs.python.org/issue?@action=redirect&bpo=22931]: Allow '[' and ']' in cookie values.
- The keywords attribute of `functools.partial` is now always a dictionary.
- [bpo-23811](https://bugs.python.org/issue?@action=redirect&bpo=23811) [https://bugs.python.org/issue?@action=redirect&bpo=23811]: Add missing newline to the `PyCompileError` error message. Patch by Alex Shkop.
- [bpo-21116](https://bugs.python.org/issue?@action=redirect&bpo=21116) [https://bugs.python.org/issue?@action=redirect&bpo=21116]: Avoid blowing memory when allocating a multiprocessing shared array that's larger than 50% of the available RAM. Patch by Médéric Boquien.
- [bpo-22982](https://bugs.python.org/issue?@action=redirect&bpo=22982) [https://bugs.python.org/issue?@action=redirect&bpo=22982]

@action=redirect&bpo=22982]: Improve BOM handling when seeking to multiple positions of a writable text file.

- [bpo-23464](https://bugs.python.org/issue?@action=redirect&bpo=23464) [https://bugs.python.org/issue?@action=redirect&bpo=23464]: Removed deprecated `asyncio.JoinableQueue`.
- [bpo-23529](https://bugs.python.org/issue?@action=redirect&bpo=23529) [https://bugs.python.org/issue?@action=redirect&bpo=23529]: Limit the size of decompressed data when reading from `GzipFile`, `BZ2File` or `LZMAFile`. This defeats denial of service attacks using compressed bombs (i.e. compressed payloads which decompress to a huge size). Patch by Martin Panter and Nikolaus Rath.
- [bpo-21859](https://bugs.python.org/issue?@action=redirect&bpo=21859) [https://bugs.python.org/issue?@action=redirect&bpo=21859]: Added Python implementation of `io.FileIO`.
- [bpo-23865](https://bugs.python.org/issue?@action=redirect&bpo=23865) [https://bugs.python.org/issue?@action=redirect&bpo=23865]: `close()` methods in multiple modules now are idempotent and more robust at shutdown. If they need to release multiple resources, all are released even if errors occur.
- [bpo-23400](https://bugs.python.org/issue?@action=redirect&bpo=23400) [https://bugs.python.org/issue?@action=redirect&bpo=23400]: Raise same exception on both Python 2 and 3 if `sem_open` is not available. Patch by Davin Potts.
- [bpo-10838](https://bugs.python.org/issue?@action=redirect&bpo=10838) [https://bugs.python.org/issue?@action=redirect&bpo=10838]: The `subprocess` now module includes `SubprocessError` and `TimeoutError` in its list of exported names for the users wild enough to use `from subprocess import *`.
- [bpo-23411](https://bugs.python.org/issue?@action=redirect&bpo=23411) [https://bugs.python.org/issue?@action=redirect&bpo=23411]: Added `DefragResult`, `ParseResult`, `SplitResult`, `DefragResultBytes`, `ParseResultBytes`, and `SplitResultBytes` to `urllib.parse._all_`. Patch by Martin Panter.
- [bpo-23881](https://bugs.python.org/issue?@action=redirect&bpo=23881) [https://bugs.python.org/issue?@action=redirect&bpo=23881]: `urllib.request.ftplibwrapper` constructor now closes the socket if the FTP connection failed to fix a `ResourceWarning`.
- [bpo-23853](https://bugs.python.org/issue?@action=redirect&bpo=23853) [https://bugs.python.org/issue?@action=redirect&bpo=23853]: `socket.socket.sendall()` does no more reset the socket timeout each time data is sent successfully. The socket timeout is now the maximum total

duration to send all data.

- [bpo-22721](https://bugs.python.org/issue?@action=redirect&bpo=22721) [https://bugs.python.org/issue?@action=redirect&bpo=22721]: An order of multiline pprint output of set or dict containing orderable and non-orderable elements no longer depends on iteration order of set or dict.
- [bpo-15133](https://bugs.python.org/issue?@action=redirect&bpo=15133) [https://bugs.python.org/issue?@action=redirect&bpo=15133]: `_tkinter.tkapp.getboolean()` now supports `Tcl_Obj` and always returns `bool`. `tkinter.BooleanVar` now validates input values (accepted `bool`, `int`, `str`, and `Tcl_Obj`). `tkinter.BooleanVar.get()` now always returns `bool`.
- [bpo-10590](https://bugs.python.org/issue?@action=redirect&bpo=10590) [https://bugs.python.org/issue?@action=redirect&bpo=10590]: `xml.sax.parseString()` now supports string argument.
- [bpo-23338](https://bugs.python.org/issue?@action=redirect&bpo=23338) [https://bugs.python.org/issue?@action=redirect&bpo=23338]: Fixed formatting ctypes error messages on Cygwin. Patch by Makoto Kato.
- [bpo-15582](https://bugs.python.org/issue?@action=redirect&bpo=15582) [https://bugs.python.org/issue?@action=redirect&bpo=15582]: `inspect.getdoc()` now follows inheritance chains.
- [bpo-2175](https://bugs.python.org/issue?@action=redirect&bpo=2175) [https://bugs.python.org/issue?@action=redirect&bpo=2175]: SAX parsers now support a character stream of `InputSource` object.
- [bpo-16840](https://bugs.python.org/issue?@action=redirect&bpo=16840) [https://bugs.python.org/issue?@action=redirect&bpo=16840]: Tkinter now supports 64-bit integers added in Tcl 8.4 and arbitrary precision integers added in Tcl 8.5.
- [bpo-23834](https://bugs.python.org/issue?@action=redirect&bpo=23834) [https://bugs.python.org/issue?@action=redirect&bpo=23834]: Fix `socket.sendto()`, use the C `Py_ssize_t` type to store the result of `sendto()` instead of the C `int` type.
- [bpo-23618](https://bugs.python.org/issue?@action=redirect&bpo=23618) [https://bugs.python.org/issue?@action=redirect&bpo=23618]: `socket.socket.connect()` now waits until the connection completes instead of raising `InterruptedError` if the connection is interrupted by signals, signal handlers don't raise an exception and the socket is blocking or has a timeout. `socket.socket.connect()` still raise `InterruptedError` for non-blocking sockets.
- [bpo-21526](https://bugs.python.org/issue?@action=redirect&bpo=21526) [https://bugs.python.org/issue?@action=redirect&bpo=21526]: Tkinter now supports new

boolean type in Tcl 8.5.

- [bpo-23836](https://bugs.python.org/issue?@action=redirect&bpo=23836) [https://bugs.python.org/issue?@action=redirect&bpo=23836]: Fix the faulthandler module to handle reentrant calls to its signal handlers.
- [bpo-23838](https://bugs.python.org/issue?@action=redirect&bpo=23838) [https://bugs.python.org/issue?@action=redirect&bpo=23838]: linecache now clears the cache and returns an empty result on MemoryError.
- [bpo-10395](https://bugs.python.org/issue?@action=redirect&bpo=10395) [https://bugs.python.org/issue?@action=redirect&bpo=10395]: Added os.path.commonpath(). Implemented in posixpath and ntpath. Based on patch by Rafik Draoui.
- [bpo-23611](https://bugs.python.org/issue?@action=redirect&bpo=23611) [https://bugs.python.org/issue?@action=redirect&bpo=23611]: Serializing more “lookupable” objects (such as unbound methods or nested classes) now are supported with pickle protocols < 4.
- [bpo-13583](https://bugs.python.org/issue?@action=redirect&bpo=13583) [https://bugs.python.org/issue?@action=redirect&bpo=13583]: sqlite3.Row now supports slice indexing.
- [bpo-18473](https://bugs.python.org/issue?@action=redirect&bpo=18473) [https://bugs.python.org/issue?@action=redirect&bpo=18473]: Fixed 2to3 and 3to2 compatible pickle mappings. Fixed ambiguous reverse mappings. Added many new mappings. Import mapping is no longer applied to modules already mapped with full name mapping.
- [bpo-23485](https://bugs.python.org/issue?@action=redirect&bpo=23485) [https://bugs.python.org/issue?@action=redirect&bpo=23485]: select.select() is now retried automatically with the recomputed timeout when interrupted by a signal, except if the signal handler raises an exception. This change is part of the [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/].
- [bpo-23752](https://bugs.python.org/issue?@action=redirect&bpo=23752) [https://bugs.python.org/issue?@action=redirect&bpo=23752]: When built from an existing file descriptor, io.FileIO() now only calls fstat() once. Before fstat() was called twice, which was not necessary.
- [bpo-23704](https://bugs.python.org/issue?@action=redirect&bpo=23704) [https://bugs.python.org/issue?@action=redirect&bpo=23704]: collections.deque() objects now support \_add\_, \_mul\_, and \_imul\_().
- [bpo-23171](https://bugs.python.org/issue?@action=redirect&bpo=23171) [https://bugs.python.org/issue?@action=redirect&bpo=23171]: csv.Writer.writerow() now supports arbitrary iterables.
- [bpo-23745](https://bugs.python.org/issue?@action=redirect&bpo=23745) [https://bugs.python.org/issue?@action=redirect&bpo=23745]

@action=redirect&bpo=23745]: The new email header parser now handles duplicate MIME parameter names without error, similar to how `get_param` behaves.

- [bpo-22117](https://bugs.python.org/issue?@action=redirect&bpo=22117) [https://bugs.python.org/issue?@action=redirect&bpo=22117]: Fix `os.utime()`, it now rounds the timestamp towards minus infinity (-inf) instead of rounding towards zero.
- [bpo-23310](https://bugs.python.org/issue?@action=redirect&bpo=23310) [https://bugs.python.org/issue?@action=redirect&bpo=23310]: Fix `MagicMock`'s initializer to work with `__methods__`, just like `configure_mock()`. Patch by Kasia Jachim.

## Build

- [bpo-23817](https://bugs.python.org/issue?@action=redirect&bpo=23817) [https://bugs.python.org/issue?@action=redirect&bpo=23817]: FreeBSD now uses “1.0” in the `SOVERSION` as other operating systems, instead of just “1”.
- [bpo-23501](https://bugs.python.org/issue?@action=redirect&bpo=23501) [https://bugs.python.org/issue?@action=redirect&bpo=23501]: `Argument Clinic` now generates code into separate files by default.

## Tests

- [bpo-23799](https://bugs.python.org/issue?@action=redirect&bpo=23799) [https://bugs.python.org/issue?@action=redirect&bpo=23799]: Added `test.support.start_threads()` for running and cleaning up multiple threads.
- [bpo-22390](https://bugs.python.org/issue?@action=redirect&bpo=22390) [https://bugs.python.org/issue?@action=redirect&bpo=22390]: `test.regrtest` now emits a warning if temporary files or directories are left after running a test.

## Tools/Demos

- [bpo-18128](https://bugs.python.org/issue?@action=redirect&bpo=18128) [https://bugs.python.org/issue?@action=redirect&bpo=18128]: `pygettext` now uses standard + NNNN format in the `POT-Creation-Date` header.
- [bpo-23935](https://bugs.python.org/issue?@action=redirect&bpo=23935) [https://bugs.python.org/issue?@action=redirect&bpo=23935]: `Argument Clinic`'s understanding of format units accepting bytes, bytearrays, and buffers is now consistent with both the documentation and the implementation.

- [bpo-23944](https://bugs.python.org/issue?@action=redirect&bpo=23944) [https://bugs.python.org/issue?@action=redirect&bpo=23944]: Argument Clinic now wraps long impl prototypes at column 78.
- [bpo-20586](https://bugs.python.org/issue?@action=redirect&bpo=20586) [https://bugs.python.org/issue?@action=redirect&bpo=20586]: Argument Clinic now ensures that functions without docstrings have signatures.
- [bpo-23492](https://bugs.python.org/issue?@action=redirect&bpo=23492) [https://bugs.python.org/issue?@action=redirect&bpo=23492]: Argument Clinic now generates argument parsing code with PyArg\_Parse instead of PyArg\_ParseTuple if possible.
- [bpo-23500](https://bugs.python.org/issue?@action=redirect&bpo=23500) [https://bugs.python.org/issue?@action=redirect&bpo=23500]: Argument Clinic is now smarter about generating the “#ifndef” (empty) definition of the methoddef macro: it’s only generated once, even if Argument Clinic processes the same symbol multiple times, and it’s emitted at the end of all processing rather than immediately after the first use.

## C API

- [bpo-23998](https://bugs.python.org/issue?@action=redirect&bpo=23998) [https://bugs.python.org/issue?@action=redirect&bpo=23998]: PyImport\_ReInitLock() now checks for lock allocation error

## Python 3.5.0 alpha 3

*Release date: 2015-03-28*

## Core and Builtins

- [bpo-23573](https://bugs.python.org/issue?@action=redirect&bpo=23573) [https://bugs.python.org/issue?@action=redirect&bpo=23573]: Increased performance of string search operations (str.find, str.index, str.count, the in operator, str.split, str.partition) with arguments of different kinds (UCS1, UCS2, UCS4).
- [bpo-23753](https://bugs.python.org/issue?@action=redirect&bpo=23753) [https://bugs.python.org/issue?@action=redirect&bpo=23753]: Python doesn’t support anymore platforms without stat() or fstat(), these functions are always required.

- [bpo-23681](https://bugs.python.org/issue?@action=redirect&bpo=23681) [https://bugs.python.org/issue?@action=redirect&bpo=23681]: The -b option now affects comparisons of bytes with int.
- [bpo-23632](https://bugs.python.org/issue?@action=redirect&bpo=23632) [https://bugs.python.org/issue?@action=redirect&bpo=23632]: Memoryviews now allow tuple indexing (including for multi-dimensional memoryviews).
- [bpo-23192](https://bugs.python.org/issue?@action=redirect&bpo=23192) [https://bugs.python.org/issue?@action=redirect&bpo=23192]: Fixed generator lambdas. Patch by Bruno Cauet.
- [bpo-23629](https://bugs.python.org/issue?@action=redirect&bpo=23629) [https://bugs.python.org/issue?@action=redirect&bpo=23629]: Fix the default `__sizeof__` implementation for variable-sized objects.

## Library

- [bpo-14260](https://bugs.python.org/issue?@action=redirect&bpo=14260) [https://bugs.python.org/issue?@action=redirect&bpo=14260]: The `groupindex` attribute of regular expression pattern object now is non-modifiable mapping.
- [bpo-23792](https://bugs.python.org/issue?@action=redirect&bpo=23792) [https://bugs.python.org/issue?@action=redirect&bpo=23792]: Ignore `KeyboardInterrupt` when the `pydoc` pager is active. This mimics the behavior of the standard unix pagers, and prevents `pipepager` from shutting down while the pager itself is still running.
- [bpo-23775](https://bugs.python.org/issue?@action=redirect&bpo=23775) [https://bugs.python.org/issue?@action=redirect&bpo=23775]: `pprint()` of `OrderedDict` now outputs the same representation as `repr()`.
- [bpo-23765](https://bugs.python.org/issue?@action=redirect&bpo=23765) [https://bugs.python.org/issue?@action=redirect&bpo=23765]: Removed `IsBadStringPtr` calls in ctypes
- [bpo-22364](https://bugs.python.org/issue?@action=redirect&bpo=22364) [https://bugs.python.org/issue?@action=redirect&bpo=22364]: Improved some re error messages using regex for hints.
- [bpo-23742](https://bugs.python.org/issue?@action=redirect&bpo=23742) [https://bugs.python.org/issue?@action=redirect&bpo=23742]: `ntpath.expandvars()` no longer loses unbalanced single quotes.
- [bpo-21717](https://bugs.python.org/issue?@action=redirect&bpo=21717) [https://bugs.python.org/issue?@action=redirect&bpo=21717]: The `zipfile.ZipFile.open` function now supports 'x' (exclusive creation) mode.
- [bpo-21802](https://bugs.python.org/issue?@action=redirect&bpo=21802) [https://bugs.python.org/issue?@action=redirect&bpo=21802]

@action=redirect&bpo=21802]: The reader in BufferedRWPair now is closed even when closing writer failed in BufferedRWPair.close().

- [bpo-23622](https://bugs.python.org/issue?@action=redirect&bpo=23622) [https://bugs.python.org/issue?@action=redirect&bpo=23622]: Unknown escapes in regular expressions that consist of ' \ ' and ASCII letter now raise a deprecation warning and will be forbidden in Python 3.6.
- [bpo-23671](https://bugs.python.org/issue?@action=redirect&bpo=23671) [https://bugs.python.org/issue?@action=redirect&bpo=23671]: string.Template now allows specifying the “self” parameter as a keyword argument. string.Formatter now allows specifying the “self” and the “format\_string” parameters as keyword arguments.
- [bpo-23502](https://bugs.python.org/issue?@action=redirect&bpo=23502) [https://bugs.python.org/issue?@action=redirect&bpo=23502]: The pprint module now supports mapping proxies.
- [bpo-17530](https://bugs.python.org/issue?@action=redirect&bpo=17530) [https://bugs.python.org/issue?@action=redirect&bpo=17530]: pprint now wraps long bytes objects and bytearray.
- [bpo-22687](https://bugs.python.org/issue?@action=redirect&bpo=22687) [https://bugs.python.org/issue?@action=redirect&bpo=22687]: Fixed some corner cases in breaking words in textwrap. Got rid of quadratic complexity in breaking long words.
- [bpo-4727](https://bugs.python.org/issue?@action=redirect&bpo=4727) [https://bugs.python.org/issue?@action=redirect&bpo=4727]: The copy module now uses pickle protocol 4 (PEP 3154) and supports copying of instances of classes whose \_new\_ method takes keyword-only arguments.
- [bpo-23491](https://bugs.python.org/issue?@action=redirect&bpo=23491) [https://bugs.python.org/issue?@action=redirect&bpo=23491]: Added a zipapp module to support creating executable zip file archives of Python code. Registered “.pyz” and “.pyzw” extensions on Windows for these archives (PEP 441).
- [bpo-23657](https://bugs.python.org/issue?@action=redirect&bpo=23657) [https://bugs.python.org/issue?@action=redirect&bpo=23657]: Avoid explicit checks for str in zipapp, adding support for pathlib.Path objects as arguments.
- [bpo-23688](https://bugs.python.org/issue?@action=redirect&bpo=23688) [https://bugs.python.org/issue?@action=redirect&bpo=23688]: Added support of arbitrary bytes-like objects and avoided unnecessary copying of memoryview in gzip.GzipFile.write(). Original patch by Wolfgang Maier.
- [bpo-23252](https://bugs.python.org/issue?@action=redirect&bpo=23252) [https://bugs.python.org/issue?@action=redirect&bpo=23252]: Added support for writing ZIP

files to unseekable streams.

- [bpo-23647](https://bugs.python.org/issue?@action=redirect&bpo=23647) [https://bugs.python.org/issue?@action=redirect&bpo=23647]: Increase imaplib's MAXLINE to accommodate modern mailbox sizes.
- [bpo-23539](https://bugs.python.org/issue?@action=redirect&bpo=23539) [https://bugs.python.org/issue?@action=redirect&bpo=23539]: If body is None, http.client.HTTPConnection.request now sets Content-Length to 0 for PUT, POST, and PATCH headers to avoid 411 errors from some web servers.
- [bpo-22351](https://bugs.python.org/issue?@action=redirect&bpo=22351) [https://bugs.python.org/issue?@action=redirect&bpo=22351]: The nntplib.NNTP constructor no longer leaves the connection and socket open until the garbage collector cleans them up. Patch by Martin Panter.
- [bpo-23704](https://bugs.python.org/issue?@action=redirect&bpo=23704) [https://bugs.python.org/issue?@action=redirect&bpo=23704]: collections.deque() objects now support methods for index(), insert(), and copy(). This allows deques to be registered as a MutableSequence and it improves their substitutability for lists.
- [bpo-23715](https://bugs.python.org/issue?@action=redirect&bpo=23715) [https://bugs.python.org/issue?@action=redirect&bpo=23715]: `signal.sigwaitinfo()` and `signal.sigtimedwait()` are now retried when interrupted by a signal not in the *sigset* parameter, if the signal handler does not raise an exception. `signal.sigtimedwait()` recomputes the timeout with a monotonic clock when it is retried.
- [bpo-23001](https://bugs.python.org/issue?@action=redirect&bpo=23001) [https://bugs.python.org/issue?@action=redirect&bpo=23001]: Few functions in modules mmap, ossaudiodev, socket, ssl, and codecs, that accepted only read-only bytes-like object now accept writable bytes-like object too.
- [bpo-23646](https://bugs.python.org/issue?@action=redirect&bpo=23646) [https://bugs.python.org/issue?@action=redirect&bpo=23646]: If `time.sleep()` is interrupted by a signal, the sleep is now retried with the recomputed delay, except if the signal handler raises an exception (PEP 475).
- [bpo-23136](https://bugs.python.org/issue?@action=redirect&bpo=23136) [https://bugs.python.org/issue?@action=redirect&bpo=23136]: `_strptime` now uniformly handles all days in week 0, including Dec 30 of previous year. Based on patch by Jim Carroll.
- [bpo-23700](https://bugs.python.org/issue?@action=redirect&bpo=23700) [https://bugs.python.org/issue?@action=redirect&bpo=23700]: Iterator of `NamedTemporaryFile`

now keeps a reference to NamedTemporaryFile instance.  
Patch by Bohuslav Kabrda.

- [bpo-22903](https://bugs.python.org/issue?@action=redirect&bpo=22903) [https://bugs.python.org/issue?@action=redirect&bpo=22903]: The fake test case created by unittest.loader when it fails importing a test module is now picklable.
- [bpo-22181](https://bugs.python.org/issue?@action=redirect&bpo=22181) [https://bugs.python.org/issue?@action=redirect&bpo=22181]: On Linux, os.urandom() now uses the new getrandom() syscall if available, syscall introduced in the Linux kernel 3.17. It is more reliable and more secure, because it avoids the need of a file descriptor and waits until the kernel has enough entropy.
- [bpo-2211](https://bugs.python.org/issue?@action=redirect&bpo=2211) [https://bugs.python.org/issue?@action=redirect&bpo=2211]: Updated the implementation of the http.cookies.Morsel class. Setting attributes key, value and coded\_value directly now is deprecated. update() and setdefault() now transform and check keys. Comparing for equality now takes into account attributes key, value and coded\_value. copy() now returns a Morsel, not a dict. repr() now contains all attributes. Optimized checking keys and quoting values. Added new tests. Original patch by Demian Brecht.
- [bpo-18983](https://bugs.python.org/issue?@action=redirect&bpo=18983) [https://bugs.python.org/issue?@action=redirect&bpo=18983]: Allow selection of output units in timeit. Patch by Julian Gindi.
- [bpo-23631](https://bugs.python.org/issue?@action=redirect&bpo=23631) [https://bugs.python.org/issue?@action=redirect&bpo=23631]: Fix traceback.format\_list when a traceback has been mutated.
- [bpo-23568](https://bugs.python.org/issue?@action=redirect&bpo=23568) [https://bugs.python.org/issue?@action=redirect&bpo=23568]: Add rdivmod support to MagicMock() objects. Patch by Håkan Lövdahl.
- [bpo-2052](https://bugs.python.org/issue?@action=redirect&bpo=2052) [https://bugs.python.org/issue?@action=redirect&bpo=2052]: Add charset parameter to HtmlDiff.make\_file().
- [bpo-23668](https://bugs.python.org/issue?@action=redirect&bpo=23668) [https://bugs.python.org/issue?@action=redirect&bpo=23668]: Support os.truncate and os.ftruncate on Windows.
- [bpo-23138](https://bugs.python.org/issue?@action=redirect&bpo=23138) [https://bugs.python.org/issue?@action=redirect&bpo=23138]: Fixed parsing cookies with absent keys or values in cookiejar. Patch by Demian Brecht.
- [bpo-23051](https://bugs.python.org/issue?@action=redirect&bpo=23051) [https://bugs.python.org/issue?@action=redirect&bpo=23051]: multiprocessing.Pool methods

`imap()` and `imap_unordered()` now handle exceptions raised by an iterator. Patch by Alon Diamant and Davin Potts.

- [bpo-23581](https://bugs.python.org/issue?@action=redirect&bpo=23581) [https://bugs.python.org/issue?@action=redirect&bpo=23581]: Add `matmul` support to `MagicMock`. Patch by Håkan Lövdahl.
- [bpo-23566](https://bugs.python.org/issue?@action=redirect&bpo=23566) [https://bugs.python.org/issue?@action=redirect&bpo=23566]: `enable()`, `register()`, `dump_traceback()` and `dump_traceback_later()` functions of `faulthandler` now accept file descriptors. Patch by Wei Wu.
- [bpo-22928](https://bugs.python.org/issue?@action=redirect&bpo=22928) [https://bugs.python.org/issue?@action=redirect&bpo=22928]: Disabled HTTP header injections in `http.client`. Original patch by Demian Brecht.
- [bpo-23615](https://bugs.python.org/issue?@action=redirect&bpo=23615) [https://bugs.python.org/issue?@action=redirect&bpo=23615]: Modules `bz2`, `tarfile` and `tokenize` now can be reloaded with `imp.reload()`. Patch by Thomas Kluyver.
- [bpo-23605](https://bugs.python.org/issue?@action=redirect&bpo=23605) [https://bugs.python.org/issue?@action=redirect&bpo=23605]: `os.walk()` now calls `os.scandir()` instead of `os.listdir()`. The usage of `os.scandir()` reduces the number of calls to `os.stat()`. Initial patch written by Ben Hoyt.

## Build

- [bpo-23585](https://bugs.python.org/issue?@action=redirect&bpo=23585) [https://bugs.python.org/issue?@action=redirect&bpo=23585]: make `patchcheck` will ensure the interpreter is built.

## Tests

- [bpo-23583](https://bugs.python.org/issue?@action=redirect&bpo=23583) [https://bugs.python.org/issue?@action=redirect&bpo=23583]: Added tests for standard IO streams in `IDLE`.
- [bpo-22289](https://bugs.python.org/issue?@action=redirect&bpo=22289) [https://bugs.python.org/issue?@action=redirect&bpo=22289]: Prevent `test_urllib2net` failures due to ftp connection timeout.

## Tools/Demos

- [bpo-22826](https://bugs.python.org/issue?@action=redirect&bpo=22826) [https://bugs.python.org/issue?@action=redirect&bpo=22826]: The result of `open()` in `Tools/`

freeze/bkfile.py is now better compatible with regular files (in particular it now supports the context management protocol).

## Python 3.5.0 alpha 2

*Release date: 2015-03-09*

### Core and Builtins

- [bpo-23571](https://bugs.python.org/issue?@action=redirect&bpo=23571) [https://bugs.python.org/issue?@action=redirect&bpo=23571]: PyObject\_Call() and PyCFunction\_Call() now raise a SystemError if a function returns a result and raises an exception. The SystemError is chained to the previous exception.

### Library

- [bpo-22524](https://bugs.python.org/issue?@action=redirect&bpo=22524) [https://bugs.python.org/issue?@action=redirect&bpo=22524]: New os.scandir() function, part of the [PEP 471](https://peps.python.org/pep-0471/) [https://peps.python.org/pep-0471/]: “os.scandir() function – a better and faster directory iterator”. Patch written by Ben Hoyt.
- [bpo-23103](https://bugs.python.org/issue?@action=redirect&bpo=23103) [https://bugs.python.org/issue?@action=redirect&bpo=23103]: Reduced the memory consumption of IPv4Address and IPv6Address.
- [bpo-21793](https://bugs.python.org/issue?@action=redirect&bpo=21793) [https://bugs.python.org/issue?@action=redirect&bpo=21793]: BaseHTTPRequestHandler again logs response code as numeric, not as stringified enum. Patch by Demian Brecht.
- [bpo-23476](https://bugs.python.org/issue?@action=redirect&bpo=23476) [https://bugs.python.org/issue?@action=redirect&bpo=23476]: In the ssl module, enable OpenSSL’s X509\_V\_FLAG\_TRUSTED\_FIRST flag on certificate stores when it is available.
- [bpo-23576](https://bugs.python.org/issue?@action=redirect&bpo=23576) [https://bugs.python.org/issue?@action=redirect&bpo=23576]: Avoid stalling in SSL reads when EOF has been reached in the SSL layer but the underlying connection hasn’t been closed.
- [bpo-23504](https://bugs.python.org/issue?@action=redirect&bpo=23504) [https://bugs.python.org/issue?@action=redirect&bpo=23504]

@action=redirect&bpo=23504]: Added an `_all_` to the types module.

- [bpo-23563](https://bugs.python.org/issue?@action=redirect&bpo=23563) [https://bugs.python.org/issue?@action=redirect&bpo=23563]: Optimized utility functions in `urllib.parse`.
- [bpo-7830](https://bugs.python.org/issue?@action=redirect&bpo=7830) [https://bugs.python.org/issue?@action=redirect&bpo=7830]: Flatten nested `functools.partial`.
- [bpo-20204](https://bugs.python.org/issue?@action=redirect&bpo=20204) [https://bugs.python.org/issue?@action=redirect&bpo=20204]: Added the `_module_` attribute to `_tkinter` classes.
- [bpo-19980](https://bugs.python.org/issue?@action=redirect&bpo=19980) [https://bugs.python.org/issue?@action=redirect&bpo=19980]: Improved `help()` for non-recognized strings. `help("")` now shows the help on `str`. `help('help')` now shows the help on `help()`. Original patch by Mark Lawrence.
- [bpo-23521](https://bugs.python.org/issue?@action=redirect&bpo=23521) [https://bugs.python.org/issue?@action=redirect&bpo=23521]: Corrected pure python implementation of `timedelta` division. Eliminated `OverflowError` from `timedelta * float` for some floats; Corrected rounding in `timedelta` true division.
- [bpo-21619](https://bugs.python.org/issue?@action=redirect&bpo=21619) [https://bugs.python.org/issue?@action=redirect&bpo=21619]: `Popen` objects no longer leave a zombie after exit in the `with` statement if the pipe was broken. Patch by Martin Panter.
- [bpo-22936](https://bugs.python.org/issue?@action=redirect&bpo=22936) [https://bugs.python.org/issue?@action=redirect&bpo=22936]: Make it possible to show local variables in tracebacks for both the `traceback` module and `unittest`.
- [bpo-15955](https://bugs.python.org/issue?@action=redirect&bpo=15955) [https://bugs.python.org/issue?@action=redirect&bpo=15955]: Add an option to limit the output size in `bz2.decompress()`. Patch by Nikolaus Rath.
- [bpo-6639](https://bugs.python.org/issue?@action=redirect&bpo=6639) [https://bugs.python.org/issue?@action=redirect&bpo=6639]: Module-level `turtle` functions no longer raise `TclError` after closing the window.
- [bpo-814253](https://bugs.python.org/issue?@action=redirect&bpo=814253) [https://bugs.python.org/issue?@action=redirect&bpo=814253]: Group references and conditional group references now work in lookbehind assertions in regular expressions. (See also: [bpo-9179](https://bugs.python.org/issue?@action=redirect&bpo=9179) [https://bugs.python.org/issue?@action=redirect&bpo=9179])
- [bpo-23215](https://bugs.python.org/issue?@action=redirect&bpo=23215) [https://bugs.python.org/issue?@action=redirect&bpo=23215]

@action=redirect&bpo=23215]: Multibyte codecs with custom error handlers that ignores errors consumed too much memory and raised `SystemError` or `MemoryError`. Original patch by Aleksi Torhamo.

- [bpo-5700](https://bugs.python.org/issue?@action=redirect&bpo=5700) [https://bugs.python.org/issue?@action=redirect&bpo=5700]: `io.FileIO()` called `flush()` after closing the file. `flush()` was not called in `close()` if `closefd = False`.
- [bpo-23374](https://bugs.python.org/issue?@action=redirect&bpo=23374) [https://bugs.python.org/issue?@action=redirect&bpo=23374]: Fixed `pydoc` failure with non-ASCII files when `stdout` encoding differs from file system encoding (e.g. on Mac OS).
- [bpo-23481](https://bugs.python.org/issue?@action=redirect&bpo=23481) [https://bugs.python.org/issue?@action=redirect&bpo=23481]: Remove RC4 from the SSL module's default cipher list.
- [bpo-21548](https://bugs.python.org/issue?@action=redirect&bpo=21548) [https://bugs.python.org/issue?@action=redirect&bpo=21548]: Fix `pydoc.synopsis()` and `pydoc.apropos()` on modules with empty docstrings.
- [bpo-22885](https://bugs.python.org/issue?@action=redirect&bpo=22885) [https://bugs.python.org/issue?@action=redirect&bpo=22885]: Fixed arbitrary code execution vulnerability in the `dbm.dumb` module. Original patch by Claudiu Popa.
- [bpo-23239](https://bugs.python.org/issue?@action=redirect&bpo=23239) [https://bugs.python.org/issue?@action=redirect&bpo=23239]: `ssl.match_hostname()` now supports matching of IP addresses.
- [bpo-23146](https://bugs.python.org/issue?@action=redirect&bpo=23146) [https://bugs.python.org/issue?@action=redirect&bpo=23146]: Fix mishandling of absolute Windows paths with forward slashes in `pathlib`.
- [bpo-23096](https://bugs.python.org/issue?@action=redirect&bpo=23096) [https://bugs.python.org/issue?@action=redirect&bpo=23096]: Pickle representation of floats with protocol 0 now is the same for both Python and C implementations.
- [bpo-19105](https://bugs.python.org/issue?@action=redirect&bpo=19105) [https://bugs.python.org/issue?@action=redirect&bpo=19105]: `pprint` now more efficiently uses free space at the right.
- [bpo-14910](https://bugs.python.org/issue?@action=redirect&bpo=14910) [https://bugs.python.org/issue?@action=redirect&bpo=14910]: Add `allow_abbrev` parameter to `argparse.ArgumentParser`. Patch by Jonathan Paugh, Steven Bethard, paul j3 and Daniel Eriksson.
- [bpo-21717](https://bugs.python.org/issue?@action=redirect&bpo=21717) [https://bugs.python.org/issue?@action=redirect&bpo=21717]: `tarfile.open()` now supports 'x'

(exclusive creation) mode.

- [bpo-23344](https://bugs.python.org/issue?@action=redirect&bpo=23344) [https://bugs.python.org/issue?@action=redirect&bpo=23344]: `marshal.dumps()` is now 20-25% faster on average.
- [bpo-20416](https://bugs.python.org/issue?@action=redirect&bpo=20416) [https://bugs.python.org/issue?@action=redirect&bpo=20416]: `marshal.dumps()` with protocols 3 and 4 is now 40-50% faster on average.
- [bpo-23421](https://bugs.python.org/issue?@action=redirect&bpo=23421) [https://bugs.python.org/issue?@action=redirect&bpo=23421]: Fixed compression in tarfile CLI. Patch by wdv4758h.
- [bpo-23367](https://bugs.python.org/issue?@action=redirect&bpo=23367) [https://bugs.python.org/issue?@action=redirect&bpo=23367]: Fix possible overflows in the `unicodedata` module.
- [bpo-23361](https://bugs.python.org/issue?@action=redirect&bpo=23361) [https://bugs.python.org/issue?@action=redirect&bpo=23361]: Fix possible overflow in Windows subprocess creation code.
- `logging.handlers.QueueListener` now takes a `respect_handler_level` keyword argument which, if set to `True`, will pass messages to handlers taking handler levels into account.
- [bpo-19705](https://bugs.python.org/issue?@action=redirect&bpo=19705) [https://bugs.python.org/issue?@action=redirect&bpo=19705]: `turtledemo` now has a visual sorting algorithm demo. Original patch from Jason Yeo.
- [bpo-23801](https://bugs.python.org/issue?@action=redirect&bpo=23801) [https://bugs.python.org/issue?@action=redirect&bpo=23801]: Fix issue where `cgi.FieldStorage` did not always ignore the entire preamble to a multipart body.

## Build

- [bpo-23445](https://bugs.python.org/issue?@action=redirect&bpo=23445) [https://bugs.python.org/issue?@action=redirect&bpo=23445]: `pydebug` builds now use “`gcc -Og`” where possible, to make the resulting executable faster.
- [bpo-23686](https://bugs.python.org/issue?@action=redirect&bpo=23686) [https://bugs.python.org/issue?@action=redirect&bpo=23686]: Update OS X 10.5 installer build to use OpenSSL 1.0.2a.

## C API

- [bpo-20204](https://bugs.python.org/issue?@action=redirect&bpo=20204) [https://bugs.python.org/issue?@action=redirect&bpo=20204]

@action=redirect&bpo=20204]: Deprecation warning is now raised for builtin types without the `_module_` attribute.

## Windows

- [bpo-23465](https://bugs.python.org/issue?@action=redirect&bpo=23465) [https://bugs.python.org/issue?@action=redirect&bpo=23465]: Implement [PEP 486](https://peps.python.org/pep-0486/) [https://peps.python.org/pep-0486/] - Make the Python Launcher aware of virtual environments. Patch by Paul Moore.
- [bpo-23437](https://bugs.python.org/issue?@action=redirect&bpo=23437) [https://bugs.python.org/issue?@action=redirect&bpo=23437]: Make user scripts directory versioned on Windows. Patch by Paul Moore.

## Python 3.5.0 alpha 1

*Release date: 2015-02-08*

### Core and Builtins

- [bpo-23285](https://bugs.python.org/issue?@action=redirect&bpo=23285) [https://bugs.python.org/issue?@action=redirect&bpo=23285]: PEP 475 - EINTR handling.
- [bpo-22735](https://bugs.python.org/issue?@action=redirect&bpo=22735) [https://bugs.python.org/issue?@action=redirect&bpo=22735]: Fix many edge cases (including crashes) involving custom `mro()` implementations.
- [bpo-22896](https://bugs.python.org/issue?@action=redirect&bpo=22896) [https://bugs.python.org/issue?@action=redirect&bpo=22896]: Avoid using `PyObject_AsCharBuffer()`, `PyObject_AsReadBuffer()` and `PyObject_AsWriteBuffer()`.
- [bpo-21295](https://bugs.python.org/issue?@action=redirect&bpo=21295) [https://bugs.python.org/issue?@action=redirect&bpo=21295]: Revert some changes ([bpo-16795](https://bugs.python.org/issue?@action=redirect&bpo=16795) [https://bugs.python.org/issue?@action=redirect&bpo=16795]) to AST line numbers and column offsets that constituted a regression.
- [bpo-22986](https://bugs.python.org/issue?@action=redirect&bpo=22986) [https://bugs.python.org/issue?@action=redirect&bpo=22986]: Allow changing an object's `_class_` between a dynamic type and static type in some cases.
- [bpo-15859](https://bugs.python.org/issue?@action=redirect&bpo=15859) [https://bugs.python.org/issue?@action=redirect&bpo=15859]: `PyUnicode_EncodeFSDefault()`, `PyUnicode_EncodeMBCS()` and `PyUnicode_EncodeCodePage()`

now raise an exception if the object is not a Unicode object. For `PyUnicode_EncodeFSDefault()`, it was already the case on platforms other than Windows. Patch written by Campbell Barton.

- [bpo-21408](https://bugs.python.org/issue?@action=redirect&bpo=21408) [https://bugs.python.org/issue?@action=redirect&bpo=21408]: The default `_ne_()` now returns `NotImplemented` if `_eq_()` returned `NotImplemented`. Original patch by Martin Panter.
- [bpo-23321](https://bugs.python.org/issue?@action=redirect&bpo=23321) [https://bugs.python.org/issue?@action=redirect&bpo=23321]: Fixed a crash in `str.decode()` when error handler returned replacement string longer than malformed input data.
- [bpo-22286](https://bugs.python.org/issue?@action=redirect&bpo=22286) [https://bugs.python.org/issue?@action=redirect&bpo=22286]: The “backslashreplace” error handlers now works with decoding and translating.
- [bpo-23253](https://bugs.python.org/issue?@action=redirect&bpo=23253) [https://bugs.python.org/issue?@action=redirect&bpo=23253]: Delay-load `ShellExecute[AW]` in `os.startfile` for reduced startup overhead on Windows.
- [bpo-22038](https://bugs.python.org/issue?@action=redirect&bpo=22038) [https://bugs.python.org/issue?@action=redirect&bpo=22038]: `pyatomic.h` now uses `stdatomic.h` or GCC built-in functions for atomic memory access if available. Patch written by Vitor de Lima and Gustavo Temple.
- [bpo-20284](https://bugs.python.org/issue?@action=redirect&bpo=20284) [https://bugs.python.org/issue?@action=redirect&bpo=20284]: `%-` interpolation (aka `printf`) formatting added for bytes and bytearray.
- [bpo-23048](https://bugs.python.org/issue?@action=redirect&bpo=23048) [https://bugs.python.org/issue?@action=redirect&bpo=23048]: Fix jumping out of an infinite while loop in the `pdb`.
- [bpo-20335](https://bugs.python.org/issue?@action=redirect&bpo=20335) [https://bugs.python.org/issue?@action=redirect&bpo=20335]: bytes constructor now raises `TypeError` when encoding or errors is specified with non-string argument. Based on patch by Renaud Blanch.
- [bpo-22834](https://bugs.python.org/issue?@action=redirect&bpo=22834) [https://bugs.python.org/issue?@action=redirect&bpo=22834]: If the current working directory ends up being set to a non-existent directory then `import` will no longer raise `FileNotFoundError`.
- [bpo-22869](https://bugs.python.org/issue?@action=redirect&bpo=22869) [https://bugs.python.org/issue?@action=redirect&bpo=22869]: Move the interpreter startup & shutdown code to a new dedicated `pylifecycle.c` module

- [bpo-22847](https://bugs.python.org/issue?@action=redirect&bpo=22847) [https://bugs.python.org/issue?@action=redirect&bpo=22847]: Improve method cache efficiency.
- [bpo-22335](https://bugs.python.org/issue?@action=redirect&bpo=22335) [https://bugs.python.org/issue?@action=redirect&bpo=22335]: Fix crash when trying to enlarge a bytearray to 0x7fffffff bytes on a 32-bit platform.
- [bpo-22653](https://bugs.python.org/issue?@action=redirect&bpo=22653) [https://bugs.python.org/issue?@action=redirect&bpo=22653]: Fix an assertion failure in debug mode when doing a reentrant dict insertion in debug mode.
- [bpo-22643](https://bugs.python.org/issue?@action=redirect&bpo=22643) [https://bugs.python.org/issue?@action=redirect&bpo=22643]: Fix integer overflow in Unicode case operations (upper, lower, title, swapcase, casefold).
- [bpo-17636](https://bugs.python.org/issue?@action=redirect&bpo=17636) [https://bugs.python.org/issue?@action=redirect&bpo=17636]: Circular imports involving relative imports are now supported.
- [bpo-22604](https://bugs.python.org/issue?@action=redirect&bpo=22604) [https://bugs.python.org/issue?@action=redirect&bpo=22604]: Fix assertion error in debug mode when dividing a complex number by (nan + 0j).
- [bpo-21052](https://bugs.python.org/issue?@action=redirect&bpo=21052) [https://bugs.python.org/issue?@action=redirect&bpo=21052]: Do not raise ImportWarning when sys.path\_hooks or sys.meta\_path are set to None.
- [bpo-16518](https://bugs.python.org/issue?@action=redirect&bpo=16518) [https://bugs.python.org/issue?@action=redirect&bpo=16518]: Use ‘bytes-like object required’ in error messages that previously used the far more cryptic “‘x’ does not support the buffer protocol”.
- [bpo-22470](https://bugs.python.org/issue?@action=redirect&bpo=22470) [https://bugs.python.org/issue?@action=redirect&bpo=22470]: Fixed integer overflow issues in “backslashreplace”, “xmlcharrefreplace”, and “surrogatepass” error handlers.
- [bpo-22540](https://bugs.python.org/issue?@action=redirect&bpo=22540) [https://bugs.python.org/issue?@action=redirect&bpo=22540]: speed up **PyObject\_IsInstance** and **PyObject\_IsSubclass** in the common case that the second argument has metaclass **type**.
- [bpo-18711](https://bugs.python.org/issue?@action=redirect&bpo=18711) [https://bugs.python.org/issue?@action=redirect&bpo=18711]: Add a new **PyErr\_FormatV** function, similar to **PyErr\_Format** but accepting a **va\_list** argument.
- [bpo-22520](https://bugs.python.org/issue?@action=redirect&bpo=22520) [https://bugs.python.org/issue?@action=redirect&bpo=22520]: Fix overflow checking when generating the repr of a unicode object.

- [bpo-22519](https://bugs.python.org/issue?@action=redirect&bpo=22519) [https://bugs.python.org/issue?@action=redirect&bpo=22519]: Fix overflow checking in `PyBytes_Repr`.
- [bpo-22518](https://bugs.python.org/issue?@action=redirect&bpo=22518) [https://bugs.python.org/issue?@action=redirect&bpo=22518]: Fix integer overflow issues in latin-1 encoding.
- [bpo-16324](https://bugs.python.org/issue?@action=redirect&bpo=16324) [https://bugs.python.org/issue?@action=redirect&bpo=16324]: `_charset` parameter of `MIMEText` now also accepts `email.charset.Charset` instances. Initial patch by Claude Paroz.
- [bpo-1764286](https://bugs.python.org/issue?@action=redirect&bpo=1764286) [https://bugs.python.org/issue?@action=redirect&bpo=1764286]: Fix `inspect.getsource()` to support decorated functions. Patch by Claudiu Popa.
- [bpo-18554](https://bugs.python.org/issue?@action=redirect&bpo=18554) [https://bugs.python.org/issue?@action=redirect&bpo=18554]: `os._all_` includes posix functions.
- [bpo-21391](https://bugs.python.org/issue?@action=redirect&bpo=21391) [https://bugs.python.org/issue?@action=redirect&bpo=21391]: Use `os.path.abspath` in the `shutil` module.
- [bpo-11471](https://bugs.python.org/issue?@action=redirect&bpo=11471) [https://bugs.python.org/issue?@action=redirect&bpo=11471]: avoid generating a `JUMP_FORWARD` instruction at the end of an if-block if there is no else-clause. Original patch by Eugene Toder.
- [bpo-22215](https://bugs.python.org/issue?@action=redirect&bpo=22215) [https://bugs.python.org/issue?@action=redirect&bpo=22215]: Now `ValueError` is raised instead of `TypeError` when `str` or `bytes` argument contains not permitted null character or byte.
- [bpo-22258](https://bugs.python.org/issue?@action=redirect&bpo=22258) [https://bugs.python.org/issue?@action=redirect&bpo=22258]: Fix the internal function `set_inheritable()` on `Illumos`. This platform exposes the function `ioctl(FIOCLEX)`, but calling it fails with `errno is ENOTTY`: “Inappropriate ioctl for device”. `set_inheritable()` now falls back to the slower `fcntl()` (`F_GETFD` and then `F_SETFD`).
- [bpo-21389](https://bugs.python.org/issue?@action=redirect&bpo=21389) [https://bugs.python.org/issue?@action=redirect&bpo=21389]: Displaying the `__qualname__` of the underlying function in the repr of a bound method.
- [bpo-22206](https://bugs.python.org/issue?@action=redirect&bpo=22206) [https://bugs.python.org/issue?@action=redirect&bpo=22206]: Using `pthread`, `PyThread_create_key()` now sets `errno` to `ENOMEM` and returns -1 (error) on integer overflow.

- [bpo-20184](https://bugs.python.org/issue?@action=redirect&bpo=20184) [https://bugs.python.org/issue?@action=redirect&bpo=20184]: Argument Clinic based signature introspection added for 30 of the builtin functions.
- [bpo-22116](https://bugs.python.org/issue?@action=redirect&bpo=22116) [https://bugs.python.org/issue?@action=redirect&bpo=22116]: C functions and methods (of the ‘builtin\_function\_or\_method’ type) can now be weakref’ed. Patch by Wei Wu.
- [bpo-22077](https://bugs.python.org/issue?@action=redirect&bpo=22077) [https://bugs.python.org/issue?@action=redirect&bpo=22077]: Improve index error messages for bytearrays, bytes, lists, and tuples by adding ‘or slices’. Added ‘, not <typename>’ for bytearrays. Original patch by Claudiu Popa.
- [bpo-20179](https://bugs.python.org/issue?@action=redirect&bpo=20179) [https://bugs.python.org/issue?@action=redirect&bpo=20179]: Apply Argument Clinic to bytes and bytearray. Patch by Tal Einat.
- [bpo-22082](https://bugs.python.org/issue?@action=redirect&bpo=22082) [https://bugs.python.org/issue?@action=redirect&bpo=22082]: Clear interned strings in slotdefs.
- Upgrade Unicode database to Unicode 7.0.0.
- [bpo-21897](https://bugs.python.org/issue?@action=redirect&bpo=21897) [https://bugs.python.org/issue?@action=redirect&bpo=21897]: Fix a crash with the `f_locals` attribute with closure variables when `frame.clear()` has been called.
- [bpo-21205](https://bugs.python.org/issue?@action=redirect&bpo=21205) [https://bugs.python.org/issue?@action=redirect&bpo=21205]: Add a new `__qualname__` attribute to generator, the qualified name, and use it in the representation of a generator (`repr(gen)`). The default name of the generator (`__name__` attribute) is now get from the function instead of the code. Use `gen.gi_code.co_name` to get the name of the code.
- [bpo-21669](https://bugs.python.org/issue?@action=redirect&bpo=21669) [https://bugs.python.org/issue?@action=redirect&bpo=21669]: With the aid of heuristics in `SyntaxError._init_`, the parser now attempts to generate more meaningful (or at least more search engine friendly) error messages when “exec” and “print” are used as statements.
- [bpo-21642](https://bugs.python.org/issue?@action=redirect&bpo=21642) [https://bugs.python.org/issue?@action=redirect&bpo=21642]: In the conditional if-else expression, allow an integer written with no space between itself and the `else` keyword (e.g. `True if 42else False`) to be valid syntax.
- [bpo-21523](https://bugs.python.org/issue?@action=redirect&bpo=21523) [https://bugs.python.org/issue?@action=redirect&bpo=21523]

@action=redirect&bpo=21523]: Fix over-pessimistic computation of the stack effect of some opcodes in the compiler. This also fixes a quadratic compilation time issue noticeable when compiling code with a large number of “and” and “or” operators.

- **bpo-21418** [<https://bugs.python.org/issue?@action=redirect&bpo=21418>]: Fix a crash in the builtin function `super()` when called without argument and without current frame (ex: embedded Python).
- **bpo-21425** [<https://bugs.python.org/issue?@action=redirect&bpo=21425>]: Fix flushing of standard streams in the interactive interpreter.
- **bpo-21435** [<https://bugs.python.org/issue?@action=redirect&bpo=21435>]: In rare cases, when running finalizers on objects in cyclic trash a bad pointer dereference could occur due to a subtle flaw in internal iteration logic.
- **bpo-21377** [<https://bugs.python.org/issue?@action=redirect&bpo=21377>]: `PyBytes_Concat()` now tries to concatenate in-place when the first argument has a reference count of 1. Patch by Nikolaus Rath.
- **bpo-20355** [<https://bugs.python.org/issue?@action=redirect&bpo=20355>]: `-W` command line options now have higher priority than the `PYTHONWARNINGS` environment variable. Patch by Arfrever.
- **bpo-21274** [<https://bugs.python.org/issue?@action=redirect&bpo=21274>]: Define `PATH_MAX` for GNU/Hurd in `Python/pythonrun.c`.
- **bpo-20904** [<https://bugs.python.org/issue?@action=redirect&bpo=20904>]: Support setting FPU precision on m68k.
- **bpo-21209** [<https://bugs.python.org/issue?@action=redirect&bpo=21209>]: Fix sending tuples to custom generator objects with the `yield from` syntax.
- **bpo-21193** [<https://bugs.python.org/issue?@action=redirect&bpo=21193>]: `pow(a, b, c)` now raises `ValueError` rather than `TypeError` when `b` is negative. Patch by Josh Rosenberg.
- **bpo-21176** [<https://bugs.python.org/issue?@action=redirect&bpo=21176>]: PEP 465: Add the ‘@’ operator for matrix multiplication.

- [bpo-21134](https://bugs.python.org/issue?@action=redirect&bpo=21134) [https://bugs.python.org/issue?@action=redirect&bpo=21134]: Fix segfault when str is called on an uninitialized UnicodeEncodeError, UnicodeDecodeError, or UnicodeTranslateError object.
- [bpo-19537](https://bugs.python.org/issue?@action=redirect&bpo=19537) [https://bugs.python.org/issue?@action=redirect&bpo=19537]: Fix PyUnicode\_DATA() alignment under m68k. Patch by Andreas Schwab.
- [bpo-20929](https://bugs.python.org/issue?@action=redirect&bpo=20929) [https://bugs.python.org/issue?@action=redirect&bpo=20929]: Add a type cast to avoid shifting a negative number.
- [bpo-20731](https://bugs.python.org/issue?@action=redirect&bpo=20731) [https://bugs.python.org/issue?@action=redirect&bpo=20731]: Properly position in source code files even if they are opened in text mode. Patch by Serhiy Storchaka.
- [bpo-20637](https://bugs.python.org/issue?@action=redirect&bpo=20637) [https://bugs.python.org/issue?@action=redirect&bpo=20637]: Key-sharing now also works for instance dictionaries of subclasses. Patch by Peter Ingebreton.
- [bpo-8297](https://bugs.python.org/issue?@action=redirect&bpo=8297) [https://bugs.python.org/issue?@action=redirect&bpo=8297]: Attributes missing from modules now include the module name in the error text. Original patch by ysj.ray.
- [bpo-19995](https://bugs.python.org/issue?@action=redirect&bpo=19995) [https://bugs.python.org/issue?@action=redirect&bpo=19995]: %c, %o, %x, and %X now raise TypeError on non-integer input.
- [bpo-19655](https://bugs.python.org/issue?@action=redirect&bpo=19655) [https://bugs.python.org/issue?@action=redirect&bpo=19655]: The ASDL parser - used by the build process to generate code for managing the Python AST in C - was rewritten. The new parser is self contained and does not require to carry long the spark.py parser-generator library; spark.py was removed from the source base.
- [bpo-12546](https://bugs.python.org/issue?@action=redirect&bpo=12546) [https://bugs.python.org/issue?@action=redirect&bpo=12546]: Allow \x00 to be used as a fill character when using str, int, float, and complex \_\_format\_\_ methods.
- [bpo-20480](https://bugs.python.org/issue?@action=redirect&bpo=20480) [https://bugs.python.org/issue?@action=redirect&bpo=20480]: Add ipaddress.reverse\_pointer. Patch by Leon Weber.
- [bpo-13598](https://bugs.python.org/issue?@action=redirect&bpo=13598) [https://bugs.python.org/issue?@action=redirect&bpo=13598]: Modify string.Formatter to support auto-numbering of replacement fields. It now

matches the behavior of `str.format()` in this regard. Patches by Phil Elson and Ramchandra Apte.

- [bpo-8931](https://bugs.python.org/issue?@action=redirect&bpo=8931) [https://bugs.python.org/issue?@action=redirect&bpo=8931]: Make alternate formatting (`#`) for type `'c'` raise an exception. In versions prior to 3.5, `#` with `'c'` had no effect. Now specifying it is an error. Patch by Torsten Landschoff.
- [bpo-23165](https://bugs.python.org/issue?@action=redirect&bpo=23165) [https://bugs.python.org/issue?@action=redirect&bpo=23165]: Perform overflow checks before allocating memory in the `_Py_char2wchar` function.

## Library

- [bpo-23399](https://bugs.python.org/issue?@action=redirect&bpo=23399) [https://bugs.python.org/issue?@action=redirect&bpo=23399]: `pyvenv` creates relative symlinks where possible.
- [bpo-20289](https://bugs.python.org/issue?@action=redirect&bpo=20289) [https://bugs.python.org/issue?@action=redirect&bpo=20289]: `cgi.FieldStorage()` now supports the context management protocol.
- [bpo-13128](https://bugs.python.org/issue?@action=redirect&bpo=13128) [https://bugs.python.org/issue?@action=redirect&bpo=13128]: Print response headers for `CONNECT` requests when `debuglevel > 0`. Patch by Demian Brecht.
- [bpo-15381](https://bugs.python.org/issue?@action=redirect&bpo=15381) [https://bugs.python.org/issue?@action=redirect&bpo=15381]: Optimized `io.BytesIO` to make less allocations and copyings.
- [bpo-22818](https://bugs.python.org/issue?@action=redirect&bpo=22818) [https://bugs.python.org/issue?@action=redirect&bpo=22818]: Splitting on a pattern that could match an empty string now raises a warning. Patterns that can only match empty strings are now rejected.
- [bpo-23099](https://bugs.python.org/issue?@action=redirect&bpo=23099) [https://bugs.python.org/issue?@action=redirect&bpo=23099]: Closing `io.BytesIO` with exported buffer is rejected now to prevent corrupting exported buffer.
- [bpo-23326](https://bugs.python.org/issue?@action=redirect&bpo=23326) [https://bugs.python.org/issue?@action=redirect&bpo=23326]: Removed `_ne_` implementations. Since fixing default `_ne_` implementation in [bpo-21408](https://bugs.python.org/issue?@action=redirect&bpo=21408) [https://bugs.python.org/issue?@action=redirect&bpo=21408] they are redundant.
- [bpo-23363](https://bugs.python.org/issue?@action=redirect&bpo=23363) [https://bugs.python.org/issue?@action=redirect&bpo=23363]: Fix possible overflow in `itertools.permutations`.

- [bpo-23364](https://bugs.python.org/issue?@action=redirect&bpo=23364) [https://bugs.python.org/issue?@action=redirect&bpo=23364]: Fix possible overflow in `itertools.product`.
- [bpo-23366](https://bugs.python.org/issue?@action=redirect&bpo=23366) [https://bugs.python.org/issue?@action=redirect&bpo=23366]: Fixed possible integer overflow in `itertools.combinations`.
- [bpo-23369](https://bugs.python.org/issue?@action=redirect&bpo=23369) [https://bugs.python.org/issue?@action=redirect&bpo=23369]: Fixed possible integer overflow in `_json.encode_basestring_ascii`.
- [bpo-23353](https://bugs.python.org/issue?@action=redirect&bpo=23353) [https://bugs.python.org/issue?@action=redirect&bpo=23353]: Fix the exception handling of generators in `PyEval_EvalFrameEx()`. At entry, save or swap the exception state even if `PyEval_EvalFrameEx()` is called with `throwflag=0`. At exit, the exception state is now always restored or swapped, not only if why is `WHY_YIELD` or `WHY_RETURN`. Patch co-written with Antoine Pitrou.
- [bpo-14099](https://bugs.python.org/issue?@action=redirect&bpo=14099) [https://bugs.python.org/issue?@action=redirect&bpo=14099]: Restored support of writing ZIP files to tellable but non-seekable streams.
- [bpo-14099](https://bugs.python.org/issue?@action=redirect&bpo=14099) [https://bugs.python.org/issue?@action=redirect&bpo=14099]: Writing to `ZipFile` and reading multiple `ZipExtFiles` is threadsafe now.
- [bpo-19361](https://bugs.python.org/issue?@action=redirect&bpo=19361) [https://bugs.python.org/issue?@action=redirect&bpo=19361]: JSON decoder now raises `JSONDecodeError` instead of `ValueError`.
- [bpo-18518](https://bugs.python.org/issue?@action=redirect&bpo=18518) [https://bugs.python.org/issue?@action=redirect&bpo=18518]: `timeit` now rejects statements which can't be compiled outside a function or a loop (e.g. "return" or "break").
- [bpo-23094](https://bugs.python.org/issue?@action=redirect&bpo=23094) [https://bugs.python.org/issue?@action=redirect&bpo=23094]: Fixed readline with frames in Python implementation of pickle.
- [bpo-23268](https://bugs.python.org/issue?@action=redirect&bpo=23268) [https://bugs.python.org/issue?@action=redirect&bpo=23268]: Fixed bugs in the comparison of `ipaddress` classes.
- [bpo-21408](https://bugs.python.org/issue?@action=redirect&bpo=21408) [https://bugs.python.org/issue?@action=redirect&bpo=21408]: Removed incorrect implementations of `__ne__()` which didn't returned `NotImplemented` if `__eq__()` returned `NotImplemented`. The default `__ne__()` now works correctly.

- [bpo-19996](https://bugs.python.org/issue?@action=redirect&bpo=19996) [https://bugs.python.org/issue?@action=redirect&bpo=19996]: **email.feedparser.FeedParser** now handles (malformed) headers with no key rather than assuming the body has started.
- [bpo-20188](https://bugs.python.org/issue?@action=redirect&bpo=20188) [https://bugs.python.org/issue?@action=redirect&bpo=20188]: Support Application-Layer Protocol Negotiation (ALPN) in the ssl module.
- [bpo-23133](https://bugs.python.org/issue?@action=redirect&bpo=23133) [https://bugs.python.org/issue?@action=redirect&bpo=23133]: Pickling of ipaddress objects now produces more compact and portable representation.
- [bpo-23248](https://bugs.python.org/issue?@action=redirect&bpo=23248) [https://bugs.python.org/issue?@action=redirect&bpo=23248]: Update ssl error codes from latest OpenSSL git master.
- [bpo-23266](https://bugs.python.org/issue?@action=redirect&bpo=23266) [https://bugs.python.org/issue?@action=redirect&bpo=23266]: Much faster implementation of ipaddress.collapse\_addresses() when there are many non-consecutive addresses.
- [bpo-23098](https://bugs.python.org/issue?@action=redirect&bpo=23098) [https://bugs.python.org/issue?@action=redirect&bpo=23098]: 64-bit dev\_t is now supported in the os module.
- [bpo-21817](https://bugs.python.org/issue?@action=redirect&bpo=21817) [https://bugs.python.org/issue?@action=redirect&bpo=21817]: When an exception is raised in a task submitted to a ProcessPoolExecutor, the remote traceback is now displayed in the parent process. Patch by Claudiu Popa.
- [bpo-15955](https://bugs.python.org/issue?@action=redirect&bpo=15955) [https://bugs.python.org/issue?@action=redirect&bpo=15955]: Add an option to limit output size when decompressing LZMA data. Patch by Nikolaus Rath and Martin Panter.
- [bpo-23250](https://bugs.python.org/issue?@action=redirect&bpo=23250) [https://bugs.python.org/issue?@action=redirect&bpo=23250]: In the http.cookies module, capitalize “HttpOnly” and “Secure” as they are written in the standard.
- [bpo-23063](https://bugs.python.org/issue?@action=redirect&bpo=23063) [https://bugs.python.org/issue?@action=redirect&bpo=23063]: In the distutils’ check command, fix parsing of reST with code or code-block directives.
- [bpo-23209](https://bugs.python.org/issue?@action=redirect&bpo=23209) [https://bugs.python.org/issue?@action=redirect&bpo=23209]: selectors.BaseSelector.get\_key() now raises a RuntimeError if the selector is closed. And

`selectors.BaseSelector.close()` now clears its internal reference to the selector mapping to break a reference cycle. Initial patch written by Martin Richard. (See also: [bpo-23225](https://bugs.python.org/issue?@action=redirect&bpo=23225) [https://bugs.python.org/issue?@action=redirect&bpo=23225])

- [bpo-17911](https://bugs.python.org/issue?@action=redirect&bpo=17911) [https://bugs.python.org/issue?@action=redirect&bpo=17911]: Provide a way to seed the linecache for a PEP-302 module without actually loading the code.
- [bpo-17911](https://bugs.python.org/issue?@action=redirect&bpo=17911) [https://bugs.python.org/issue?@action=redirect&bpo=17911]: Provide a new object API for traceback, including the ability to not lookup lines at all until the traceback is actually rendered, without any trace of the original objects being kept alive.
- [bpo-19777](https://bugs.python.org/issue?@action=redirect&bpo=19777) [https://bugs.python.org/issue?@action=redirect&bpo=19777]: Provide a `home()` classmethod on Path objects. Contributed by Victor Salgado and Mayank Tripathi.
- [bpo-23206](https://bugs.python.org/issue?@action=redirect&bpo=23206) [https://bugs.python.org/issue?@action=redirect&bpo=23206]: Make `json.dumps(..., ensure_ascii=False)` as fast as the default case of `ensure_ascii=True`. Patch by Naoki Inada.
- [bpo-23185](https://bugs.python.org/issue?@action=redirect&bpo=23185) [https://bugs.python.org/issue?@action=redirect&bpo=23185]: Add `math.inf` and `math.nan` constants.
- [bpo-23186](https://bugs.python.org/issue?@action=redirect&bpo=23186) [https://bugs.python.org/issue?@action=redirect&bpo=23186]: Add `ssl.SSLObject.shared_ciphers()` and `ssl.SSLSocket.shared_ciphers()` to fetch the client's list ciphers sent at handshake.
- [bpo-23143](https://bugs.python.org/issue?@action=redirect&bpo=23143) [https://bugs.python.org/issue?@action=redirect&bpo=23143]: Remove compatibility with OpenSSLs older than 0.9.8.
- [bpo-23132](https://bugs.python.org/issue?@action=redirect&bpo=23132) [https://bugs.python.org/issue?@action=redirect&bpo=23132]: Improve performance and introspection support of comparison methods created by `functool.total_ordering`.
- [bpo-19776](https://bugs.python.org/issue?@action=redirect&bpo=19776) [https://bugs.python.org/issue?@action=redirect&bpo=19776]: Add an `expanduser()` method on Path objects.
- [bpo-23112](https://bugs.python.org/issue?@action=redirect&bpo=23112) [https://bugs.python.org/issue?@action=redirect&bpo=23112]

@action=redirect&bpo=23112]: Fix SimpleHTTPServer to correctly carry the query string and fragment when it redirects to add a trailing slash.

- [bpo-21793](https://bugs.python.org/issue?@action=redirect&bpo=21793) [https://bugs.python.org/issue?@action=redirect&bpo=21793]: Added http.HTTPStatus enums (i.e. HTTPStatus.OK, HTTPStatus.NOT\_FOUND). Patch by Demian Brecht.
- [bpo-23093](https://bugs.python.org/issue?@action=redirect&bpo=23093) [https://bugs.python.org/issue?@action=redirect&bpo=23093]: In the io, module allow more operations to work on detached streams.
- [bpo-23111](https://bugs.python.org/issue?@action=redirect&bpo=23111) [https://bugs.python.org/issue?@action=redirect&bpo=23111]: In the ftplib, make ssl.PROTOCOL\_SSLv23 the default protocol version.
- [bpo-22585](https://bugs.python.org/issue?@action=redirect&bpo=22585) [https://bugs.python.org/issue?@action=redirect&bpo=22585]: On OpenBSD 5.6 and newer, os.urandom() now calls getentropy(), instead of reading /dev/urandom, to get pseudo-random bytes.
- [bpo-19104](https://bugs.python.org/issue?@action=redirect&bpo=19104) [https://bugs.python.org/issue?@action=redirect&bpo=19104]: pprint now produces evaluable output for wrapped strings.
- [bpo-23071](https://bugs.python.org/issue?@action=redirect&bpo=23071) [https://bugs.python.org/issue?@action=redirect&bpo=23071]: Added missing names to codecs.\_all\_. Patch by Martin Panter.
- [bpo-22783](https://bugs.python.org/issue?@action=redirect&bpo=22783) [https://bugs.python.org/issue?@action=redirect&bpo=22783]: Pickling now uses the NEWOBJ opcode instead of the NEWOBJ\_EX opcode if possible.
- [bpo-15513](https://bugs.python.org/issue?@action=redirect&bpo=15513) [https://bugs.python.org/issue?@action=redirect&bpo=15513]: Added a \_sizeof\_ implementation for pickle classes.
- [bpo-19858](https://bugs.python.org/issue?@action=redirect&bpo=19858) [https://bugs.python.org/issue?@action=redirect&bpo=19858]: pickletools.optimize() now aware of the MEMOIZE opcode, can produce more compact result and no longer produces invalid output if input data contains MEMOIZE opcodes together with PUT or BINPUT opcodes.
- [bpo-22095](https://bugs.python.org/issue?@action=redirect&bpo=22095) [https://bugs.python.org/issue?@action=redirect&bpo=22095]: Fixed HTTPConnection.set\_tunnel with default port. The port value in the host header was set to "None". Patch by Demian Brecht.
- [bpo-23016](https://bugs.python.org/issue?@action=redirect&bpo=23016) [https://bugs.python.org/issue?@action=redirect&bpo=23016]: A warning no longer produces an

AttributeError when the program is run with pythonw.exe.

- [bpo-21775](https://bugs.python.org/issue?@action=redirect&bpo=21775) [https://bugs.python.org/issue?@action=redirect&bpo=21775]: `shutil.copytree()`: fix crash when copying to VFAT. An exception handler assumed that `OSError` objects always have a 'winerror' attribute. That is not the case, so the exception handler itself raised `AttributeError` when run on Linux (and, presumably, any other non-Windows OS). Patch by Greg Ward.
- [bpo-1218234](https://bugs.python.org/issue?@action=redirect&bpo=1218234) [https://bugs.python.org/issue?@action=redirect&bpo=1218234]: Fix `inspect.getsource()` to load updated source of reloaded module. Initial patch by Berker Peksag.
- [bpo-21740](https://bugs.python.org/issue?@action=redirect&bpo=21740) [https://bugs.python.org/issue?@action=redirect&bpo=21740]: Support wrapped callables in `doctest`. Patch by Claudiu Popa.
- [bpo-23009](https://bugs.python.org/issue?@action=redirect&bpo=23009) [https://bugs.python.org/issue?@action=redirect&bpo=23009]: Make sure `selectors.EpollSelector.select()` works when no FD is registered.
- [bpo-22959](https://bugs.python.org/issue?@action=redirect&bpo=22959) [https://bugs.python.org/issue?@action=redirect&bpo=22959]: In the constructor of `http.client.HTTPSConnection`, prefer the context's `check_hostname` attribute over the `check_hostname` parameter.
- [bpo-22696](https://bugs.python.org/issue?@action=redirect&bpo=22696) [https://bugs.python.org/issue?@action=redirect&bpo=22696]: Add function `sys.is_finalizing()` to know about interpreter shutdown.
- [bpo-16043](https://bugs.python.org/issue?@action=redirect&bpo=16043) [https://bugs.python.org/issue?@action=redirect&bpo=16043]: Add a default limit for the amount of data `xmlrpclib.gzip_decode` will return. This resolves CVE-2013-1753.
- [bpo-14099](https://bugs.python.org/issue?@action=redirect&bpo=14099) [https://bugs.python.org/issue?@action=redirect&bpo=14099]: `ZipFile.open()` no longer reopen the underlying file. Objects returned by `ZipFile.open()` can now operate independently of the `ZipFile` even if the `ZipFile` was created by passing in a file-like object as the first argument to the constructor.
- [bpo-22966](https://bugs.python.org/issue?@action=redirect&bpo=22966) [https://bugs.python.org/issue?@action=redirect&bpo=22966]: Fix `_pycache_` pyc file name clobber when `pyc_compile` is asked to compile a source file

containing multiple dots in the source file name.

- [bpo-21971](https://bugs.python.org/issue?@action=redirect&bpo=21971) [https://bugs.python.org/issue?@action=redirect&bpo=21971]: Update `turtledemo` doc and add module to the index.
- [bpo-21032](https://bugs.python.org/issue?@action=redirect&bpo=21032) [https://bugs.python.org/issue?@action=redirect&bpo=21032]: Fixed socket leak if `HTTPConnection.getresponse()` fails. Original patch by Martin Panter.
- [bpo-22407](https://bugs.python.org/issue?@action=redirect&bpo=22407) [https://bugs.python.org/issue?@action=redirect&bpo=22407]: Deprecated the use of `re.LOCALE` flag with `str` patterns or `re.ASCII`. It was newer worked.
- [bpo-22902](https://bugs.python.org/issue?@action=redirect&bpo=22902) [https://bugs.python.org/issue?@action=redirect&bpo=22902]: The “ip” command is now used on Linux to determine MAC address in `uuid.getnode()`. Pach by Bruno Cauet.
- [bpo-22960](https://bugs.python.org/issue?@action=redirect&bpo=22960) [https://bugs.python.org/issue?@action=redirect&bpo=22960]: Add a context argument to `xmlrpclib.ServerProxy` constructor.
- [bpo-22389](https://bugs.python.org/issue?@action=redirect&bpo=22389) [https://bugs.python.org/issue?@action=redirect&bpo=22389]: Add `contextlib.redirect_stderr()`.
- [bpo-21356](https://bugs.python.org/issue?@action=redirect&bpo=21356) [https://bugs.python.org/issue?@action=redirect&bpo=21356]: Make `ssl.RAND_egd()` optional to support LibreSSL. The availability of the function is checked during the compilation. Patch written by Bernard Spil.
- [bpo-22915](https://bugs.python.org/issue?@action=redirect&bpo=22915) [https://bugs.python.org/issue?@action=redirect&bpo=22915]: SAX parser now supports files opened with file descriptor or bytes path.
- [bpo-22609](https://bugs.python.org/issue?@action=redirect&bpo=22609) [https://bugs.python.org/issue?@action=redirect&bpo=22609]: Constructors and update methods of mapping classes in the `collections` module now accept the `self` keyword argument.
- [bpo-22940](https://bugs.python.org/issue?@action=redirect&bpo=22940) [https://bugs.python.org/issue?@action=redirect&bpo=22940]: Add `readline.append_history_file`.
- [bpo-19676](https://bugs.python.org/issue?@action=redirect&bpo=19676) [https://bugs.python.org/issue?@action=redirect&bpo=19676]: Added the “namereplace” error handler.
- [bpo-22788](https://bugs.python.org/issue?@action=redirect&bpo=22788) [https://bugs.python.org/issue?@action=redirect&bpo=22788]: Add *context* parameter to `logging.handlers.HTTPHandler`.
- [bpo-22921](https://bugs.python.org/issue?@action=redirect&bpo=22921) [https://bugs.python.org/issue?@action=redirect&bpo=22921]

@action=redirect&bpo=22921]: Allow SSLContext to take the *hostname* parameter even if OpenSSL doesn't support SNI.

- [bpo-22894](https://bugs.python.org/issue?@action=redirect&bpo=22894) [https://bugs.python.org/issue?@action=redirect&bpo=22894]: TestCase.subTest() would cause the test suite to be stopped when in failfast mode, even in the absence of failures.
- [bpo-22796](https://bugs.python.org/issue?@action=redirect&bpo=22796) [https://bugs.python.org/issue?@action=redirect&bpo=22796]: HTTP cookie parsing is now stricter, in order to protect against potential injection attacks.
- [bpo-22370](https://bugs.python.org/issue?@action=redirect&bpo=22370) [https://bugs.python.org/issue?@action=redirect&bpo=22370]: Windows detection in pathlib is now more robust.
- [bpo-22841](https://bugs.python.org/issue?@action=redirect&bpo=22841) [https://bugs.python.org/issue?@action=redirect&bpo=22841]: Reject coroutines in asyncio add\_signal\_handler(). Patch by Ludovic.Gasc.
- [bpo-19494](https://bugs.python.org/issue?@action=redirect&bpo=19494) [https://bugs.python.org/issue?@action=redirect&bpo=19494]: Added urllib.request.HTTPBasicPriorAuthHandler. Patch by Matej Cepl.
- [bpo-22578](https://bugs.python.org/issue?@action=redirect&bpo=22578) [https://bugs.python.org/issue?@action=redirect&bpo=22578]: Added attributes to the re.error class.
- [bpo-22849](https://bugs.python.org/issue?@action=redirect&bpo=22849) [https://bugs.python.org/issue?@action=redirect&bpo=22849]: Fix possible double free in the io.TextIOWrapper constructor.
- [bpo-12728](https://bugs.python.org/issue?@action=redirect&bpo=12728) [https://bugs.python.org/issue?@action=redirect&bpo=12728]: Different Unicode characters having the same uppercase but different lowercase are now matched in case-insensitive regular expressions.
- [bpo-22821](https://bugs.python.org/issue?@action=redirect&bpo=22821) [https://bugs.python.org/issue?@action=redirect&bpo=22821]: Fixed fcntl() with integer argument on 64-bit big-endian platforms.
- [bpo-21650](https://bugs.python.org/issue?@action=redirect&bpo=21650) [https://bugs.python.org/issue?@action=redirect&bpo=21650]: Add an **--sort-keys** option to json.tool CLI.
- [bpo-22824](https://bugs.python.org/issue?@action=redirect&bpo=22824) [https://bugs.python.org/issue?@action=redirect&bpo=22824]: Updated reprlib output format for sets to use set literals. Patch contributed by Berker Peksag.
- [bpo-22824](https://bugs.python.org/issue?@action=redirect&bpo=22824) [https://bugs.python.org/issue?@action=redirect&bpo=22824]: Updated reprlib output format for

arrays to display empty arrays without an unnecessary empty list. Suggested by Serhiy Storchaka.

- [bpo-22406](https://bugs.python.org/issue?@action=redirect&bpo=22406) [https://bugs.python.org/issue?@action=redirect&bpo=22406]: Fixed the uu\_codec codec incorrectly ported to 3.x. Based on patch by Martin Panther.
- [bpo-17293](https://bugs.python.org/issue?@action=redirect&bpo=17293) [https://bugs.python.org/issue?@action=redirect&bpo=17293]: uuid.getnode() now determines MAC address on AIX using netstat. Based on patch by Aivars Kalvāns.
- [bpo-22769](https://bugs.python.org/issue?@action=redirect&bpo=22769) [https://bugs.python.org/issue?@action=redirect&bpo=22769]: Fixed ttk.Treeview.tag\_has() when called without arguments.
- [bpo-22417](https://bugs.python.org/issue?@action=redirect&bpo=22417) [https://bugs.python.org/issue?@action=redirect&bpo=22417]: Verify certificates by default in httplib (PEP 476).
- [bpo-22775](https://bugs.python.org/issue?@action=redirect&bpo=22775) [https://bugs.python.org/issue?@action=redirect&bpo=22775]: Fixed unpickling of http.cookies.SimpleCookie with protocol 2 and above. Patch by Tim Graham.
- [bpo-22776](https://bugs.python.org/issue?@action=redirect&bpo=22776) [https://bugs.python.org/issue?@action=redirect&bpo=22776]: Brought excluded code into the scope of a try block in SysLogHandler.emit().
- [bpo-22665](https://bugs.python.org/issue?@action=redirect&bpo=22665) [https://bugs.python.org/issue?@action=redirect&bpo=22665]: Add missing get\_terminal\_size and SameFileError to shutil.\_all\_.
- [bpo-6623](https://bugs.python.org/issue?@action=redirect&bpo=6623) [https://bugs.python.org/issue?@action=redirect&bpo=6623]: Remove deprecated Netrc class in the ftplib module. Patch by Matt Chaput.
- [bpo-17381](https://bugs.python.org/issue?@action=redirect&bpo=17381) [https://bugs.python.org/issue?@action=redirect&bpo=17381]: Fixed handling of case-insensitive ranges in regular expressions.
- [bpo-22410](https://bugs.python.org/issue?@action=redirect&bpo=22410) [https://bugs.python.org/issue?@action=redirect&bpo=22410]: Module level functions in the re module now cache compiled locale-dependent regular expressions taking into account the locale.
- [bpo-22759](https://bugs.python.org/issue?@action=redirect&bpo=22759) [https://bugs.python.org/issue?@action=redirect&bpo=22759]: Query methods on pathlib.Path() (exists(), is\_dir(), etc.) now return False when the underlying stat call raises NotADirectoryError.
- [bpo-8876](https://bugs.python.org/issue?@action=redirect&bpo=8876) [https://bugs.python.org/issue?@action=redirect&bpo=8876]:

distutils now falls back to copying files when hard linking doesn't work. This allows use with special filesystems such as VirtualBox shared folders.

- [bpo-22217](https://bugs.python.org/issue?@action=redirect&bpo=22217) [https://bugs.python.org/issue?@action=redirect&bpo=22217]: Implemented reprs of classes in the zipfile module.
- [bpo-22457](https://bugs.python.org/issue?@action=redirect&bpo=22457) [https://bugs.python.org/issue?@action=redirect&bpo=22457]: Honour load\_tests in the start\_dir of discovery.
- [bpo-18216](https://bugs.python.org/issue?@action=redirect&bpo=18216) [https://bugs.python.org/issue?@action=redirect&bpo=18216]: gettext now raises an error when a .mo file has an unsupported major version number. Patch by Aaron Hill.
- [bpo-13918](https://bugs.python.org/issue?@action=redirect&bpo=13918) [https://bugs.python.org/issue?@action=redirect&bpo=13918]: Provide a locale.delocalize() function which can remove locale-specific number formatting from a string representing a number, without then converting it to a specific type. Patch by Cédric Krier.
- [bpo-22676](https://bugs.python.org/issue?@action=redirect&bpo=22676) [https://bugs.python.org/issue?@action=redirect&bpo=22676]: Make the pickling of global objects which don't have a \_\_module\_\_ attribute less slow.
- [bpo-18853](https://bugs.python.org/issue?@action=redirect&bpo=18853) [https://bugs.python.org/issue?@action=redirect&bpo=18853]: Fixed ResourceWarning in shlex.\_nain\_.
- [bpo-9351](https://bugs.python.org/issue?@action=redirect&bpo=9351) [https://bugs.python.org/issue?@action=redirect&bpo=9351]: Defaults set with set\_defaults on an argparse subparser are no longer ignored when also set on the parent parser.
- [bpo-7559](https://bugs.python.org/issue?@action=redirect&bpo=7559) [https://bugs.python.org/issue?@action=redirect&bpo=7559]: unittest test loading ImportErrors are reported as import errors with their import exception rather than as attribute errors after the import has already failed.
- [bpo-19746](https://bugs.python.org/issue?@action=redirect&bpo=19746) [https://bugs.python.org/issue?@action=redirect&bpo=19746]: Make it possible to examine the errors from unittest discovery without executing the test suite. The new **errors** attribute on TestLoader exposes these non-fatal errors encountered during discovery.
- [bpo-21991](https://bugs.python.org/issue?@action=redirect&bpo=21991) [https://bugs.python.org/issue?@action=redirect&bpo=21991]: Make email.headerregistry's header 'params' attributes be read-only (MappingProxyType). Previously the dictionary was modifiable but a new one was

created on each access of the attribute.

- [bpo-22638](https://bugs.python.org/issue?@action=redirect&bpo=22638) [https://bugs.python.org/issue?@action=redirect&bpo=22638]: SSLv3 is now disabled throughout the standard library. It can still be enabled by instantiating a SSLContext manually.
- [bpo-22641](https://bugs.python.org/issue?@action=redirect&bpo=22641) [https://bugs.python.org/issue?@action=redirect&bpo=22641]: In asyncio, the default SSL context for client connections is now created using ssl.create\_default\_context(), for stronger security.
- [bpo-17401](https://bugs.python.org/issue?@action=redirect&bpo=17401) [https://bugs.python.org/issue?@action=redirect&bpo=17401]: Include closefd in io.FileIO repr.
- [bpo-21338](https://bugs.python.org/issue?@action=redirect&bpo=21338) [https://bugs.python.org/issue?@action=redirect&bpo=21338]: Add silent mode for compileall. quiet parameters of compile\_{dir, file, path} functions now have a multilevel value. Also, -q option of the CLI now have a multilevel value. Patch by Thomas Kluyver.
- [bpo-20152](https://bugs.python.org/issue?@action=redirect&bpo=20152) [https://bugs.python.org/issue?@action=redirect&bpo=20152]: Convert the array and cmath modules to Argument Clinic.
- [bpo-18643](https://bugs.python.org/issue?@action=redirect&bpo=18643) [https://bugs.python.org/issue?@action=redirect&bpo=18643]: Add socket.socketpair() on Windows.
- [bpo-22435](https://bugs.python.org/issue?@action=redirect&bpo=22435) [https://bugs.python.org/issue?@action=redirect&bpo=22435]: Fix a file descriptor leak when socketserver bind fails.
- [bpo-13096](https://bugs.python.org/issue?@action=redirect&bpo=13096) [https://bugs.python.org/issue?@action=redirect&bpo=13096]: Fixed segfault in CTypes POINTER handling of large values.
- [bpo-11694](https://bugs.python.org/issue?@action=redirect&bpo=11694) [https://bugs.python.org/issue?@action=redirect&bpo=11694]: Raise ConversionError in xdrllib as documented. Patch by Filip Gruszczyński and Claudiu Popa.
- [bpo-19380](https://bugs.python.org/issue?@action=redirect&bpo=19380) [https://bugs.python.org/issue?@action=redirect&bpo=19380]: Optimized parsing of regular expressions.
- [bpo-1519638](https://bugs.python.org/issue?@action=redirect&bpo=1519638) [https://bugs.python.org/issue?@action=redirect&bpo=1519638]: Now unmatched groups are replaced with empty strings in re.sub() and re.subn().
- [bpo-18615](https://bugs.python.org/issue?@action=redirect&bpo=18615) [https://bugs.python.org/issue?@action=redirect&bpo=18615]: sndhdr.what/whathdr now return a namedtuple.

- [bpo-22462](https://bugs.python.org/issue?@action=redirect&bpo=22462) [https://bugs.python.org/issue?@action=redirect&bpo=22462]: Fix pyexpat's creation of a dummy frame to make it appear in exception tracebacks.
- [bpo-21965](https://bugs.python.org/issue?@action=redirect&bpo=21965) [https://bugs.python.org/issue?@action=redirect&bpo=21965]: Add support for in-memory SSL to the ssl module. Patch by Geert Jansen.
- [bpo-21173](https://bugs.python.org/issue?@action=redirect&bpo=21173) [https://bugs.python.org/issue?@action=redirect&bpo=21173]: Fix len() on a WeakKeyDictionary when .clear() was called with an iterator alive.
- [bpo-11866](https://bugs.python.org/issue?@action=redirect&bpo=11866) [https://bugs.python.org/issue?@action=redirect&bpo=11866]: Eliminated race condition in the computation of names for new threads.
- [bpo-21905](https://bugs.python.org/issue?@action=redirect&bpo=21905) [https://bugs.python.org/issue?@action=redirect&bpo=21905]: Avoid RuntimeError in pickle.whichmodule() when sys.modules is mutated while iterating. Patch by Olivier Grisel.
- [bpo-11271](https://bugs.python.org/issue?@action=redirect&bpo=11271) [https://bugs.python.org/issue?@action=redirect&bpo=11271]: concurrent.futures.Executor.map() now takes a *chunksize* argument to allow batching of tasks in child processes and improve performance of ProcessPoolExecutor. Patch by Dan O'Reilly.
- [bpo-21883](https://bugs.python.org/issue?@action=redirect&bpo=21883) [https://bugs.python.org/issue?@action=redirect&bpo=21883]: os.path.join() and os.path.relpath() now raise a TypeError with more helpful error message for unsupported or mismatched types of arguments.
- [bpo-22219](https://bugs.python.org/issue?@action=redirect&bpo=22219) [https://bugs.python.org/issue?@action=redirect&bpo=22219]: The zipfile module CLI now adds entries for directories (including empty directories) in ZIP file.
- [bpo-22449](https://bugs.python.org/issue?@action=redirect&bpo=22449) [https://bugs.python.org/issue?@action=redirect&bpo=22449]: In the ssl.SSLContext.load\_default\_certs, consult the environmental variables SSL\_CERT\_DIR and SSL\_CERT\_FILE on Windows.
- [bpo-22508](https://bugs.python.org/issue?@action=redirect&bpo=22508) [https://bugs.python.org/issue?@action=redirect&bpo=22508]: The email.\_version\_ variable has been removed; the email code is no longer shipped separately from the stdlib, and \_version\_ hasn't been updated in several releases.
- [bpo-20076](https://bugs.python.org/issue?@action=redirect&bpo=20076) [https://bugs.python.org/issue?@action=redirect&bpo=20076]

@action=redirect&bpo=20076]: Added non derived UTF-8 aliases to locale aliases table.

- [bpo-20079](https://bugs.python.org/issue?@action=redirect&bpo=20079) [https://bugs.python.org/issue?@action=redirect&bpo=20079]: Added locales supported in glibc 2.18 to locale alias table.
- [bpo-20218](https://bugs.python.org/issue?@action=redirect&bpo=20218) [https://bugs.python.org/issue?@action=redirect&bpo=20218]: Added convenience methods read\_text/write\_text and read\_bytes/ write\_bytes to pathlib.Path objects.
- [bpo-22396](https://bugs.python.org/issue?@action=redirect&bpo=22396) [https://bugs.python.org/issue?@action=redirect&bpo=22396]: On 32-bit AIX platform, don't expose os.posix\_fadvise() nor os.posix\_fallocate() because their prototypes in system headers are wrong.
- [bpo-22517](https://bugs.python.org/issue?@action=redirect&bpo=22517) [https://bugs.python.org/issue?@action=redirect&bpo=22517]: When an io.BufferedRWPair object is deallocated, clear its weakrefs.
- [bpo-22437](https://bugs.python.org/issue?@action=redirect&bpo=22437) [https://bugs.python.org/issue?@action=redirect&bpo=22437]: Number of capturing groups in regular expression is no longer limited by 100.
- [bpo-17442](https://bugs.python.org/issue?@action=redirect&bpo=17442) [https://bugs.python.org/issue?@action=redirect&bpo=17442]: InteractiveInterpreter now displays the full chained traceback in its showtraceback method, to match the built in interactive interpreter.
- [bpo-23392](https://bugs.python.org/issue?@action=redirect&bpo=23392) [https://bugs.python.org/issue?@action=redirect&bpo=23392]: Added tests for marshal C API that works with FILE\*.
- [bpo-10510](https://bugs.python.org/issue?@action=redirect&bpo=10510) [https://bugs.python.org/issue?@action=redirect&bpo=10510]: distutils register and upload methods now use HTML standards compliant CRLF line endings.
- [bpo-9850](https://bugs.python.org/issue?@action=redirect&bpo=9850) [https://bugs.python.org/issue?@action=redirect&bpo=9850]: Fixed macpath.join() for empty first component. Patch by Oleg Oshmyan.
- [bpo-5309](https://bugs.python.org/issue?@action=redirect&bpo=5309) [https://bugs.python.org/issue?@action=redirect&bpo=5309]: distutils' build and build\_ext commands now accept a -j option to enable parallel building of extension modules.
- [bpo-22448](https://bugs.python.org/issue?@action=redirect&bpo=22448) [https://bugs.python.org/issue?@action=redirect&bpo=22448]: Improve canceled timer handles cleanup to prevent unbound memory usage. Patch by Joshua Moore-Oliva.

- [bpo-22427](https://bugs.python.org/issue?@action=redirect&bpo=22427) [https://bugs.python.org/issue?@action=redirect&bpo=22427]: TemporaryDirectory no longer attempts to clean up twice when used in the with statement in generator.
- [bpo-22362](https://bugs.python.org/issue?@action=redirect&bpo=22362) [https://bugs.python.org/issue?@action=redirect&bpo=22362]: Forbidden ambiguous octal escapes out of range 0-0o377 in regular expressions.
- [bpo-20912](https://bugs.python.org/issue?@action=redirect&bpo=20912) [https://bugs.python.org/issue?@action=redirect&bpo=20912]: Now directories added to ZIP file have correct Unix and MS-DOS directory attributes.
- [bpo-21866](https://bugs.python.org/issue?@action=redirect&bpo=21866) [https://bugs.python.org/issue?@action=redirect&bpo=21866]: ZipFile.close() no longer writes ZIP64 central directory records if allowZip64 is false.
- [bpo-22278](https://bugs.python.org/issue?@action=redirect&bpo=22278) [https://bugs.python.org/issue?@action=redirect&bpo=22278]: Fix urljoin problem with relative urls, a regression observed after changes to issue22118 were submitted.
- [bpo-22415](https://bugs.python.org/issue?@action=redirect&bpo=22415) [https://bugs.python.org/issue?@action=redirect&bpo=22415]: Fixed debugging output of the GROUPREF\_EXISTS opcode in the re module. Removed trailing spaces in debugging output.
- [bpo-22423](https://bugs.python.org/issue?@action=redirect&bpo=22423) [https://bugs.python.org/issue?@action=redirect&bpo=22423]: Unhandled exception in thread no longer causes unhandled AttributeError when sys.stderr is None.
- [bpo-21332](https://bugs.python.org/issue?@action=redirect&bpo=21332) [https://bugs.python.org/issue?@action=redirect&bpo=21332]: Ensure that bufsize=1 in subprocess.Popen() selects line buffering, rather than block buffering. Patch by Akira Li.
- [bpo-21091](https://bugs.python.org/issue?@action=redirect&bpo=21091) [https://bugs.python.org/issue?@action=redirect&bpo=21091]: Fix API bug: email.message.EmailMessage.is\_attachment is now a method.
- [bpo-21079](https://bugs.python.org/issue?@action=redirect&bpo=21079) [https://bugs.python.org/issue?@action=redirect&bpo=21079]: Fix email.message.EmailMessage.is\_attachment to return the correct result when the header has parameters as well as a value.
- [bpo-22247](https://bugs.python.org/issue?@action=redirect&bpo=22247) [https://bugs.python.org/issue?@action=redirect&bpo=22247]: Add NNTPErrors to nntplib.\_all\_.
- [bpo-22366](https://bugs.python.org/issue?@action=redirect&bpo=22366) [https://bugs.python.org/issue?@action=redirect&bpo=22366]

@action=redirect&bpo=22366]: urllib.request.urlopen will accept a context object (SSLContext) as an argument which will then be used for HTTPS connection. Patch by Alex Gaynor.

- [bpo-4180](https://bugs.python.org/issue?@action=redirect&bpo=4180) [https://bugs.python.org/issue?@action=redirect&bpo=4180]: The warnings registries are now reset when the filters are modified.
- [bpo-22419](https://bugs.python.org/issue?@action=redirect&bpo=22419) [https://bugs.python.org/issue?@action=redirect&bpo=22419]: Limit the length of incoming HTTP request in wsgiref server to 65536 bytes and send a 414 error code for higher lengths. Patch contributed by Devin Cook.
- Lax cookie parsing in http.cookies could be a security issue when combined with non-standard cookie handling in some web browsers. Reported by Sergey Bobrov.
- [bpo-20537](https://bugs.python.org/issue?@action=redirect&bpo=20537) [https://bugs.python.org/issue?@action=redirect&bpo=20537]: logging methods now accept an exception instance as well as a Boolean value or exception tuple. Thanks to Yuri Selivanov for the patch.
- [bpo-22384](https://bugs.python.org/issue?@action=redirect&bpo=22384) [https://bugs.python.org/issue?@action=redirect&bpo=22384]: An exception in Tkinter callback no longer crashes the program when it is run with pythonw.exe.
- [bpo-22168](https://bugs.python.org/issue?@action=redirect&bpo=22168) [https://bugs.python.org/issue?@action=redirect&bpo=22168]: Prevent turtle AttributeError with non-default Canvas on OS X.
- [bpo-21147](https://bugs.python.org/issue?@action=redirect&bpo=21147) [https://bugs.python.org/issue?@action=redirect&bpo=21147]: sqlite3 now raises an exception if the request contains a null character instead of truncating it. Based on patch by Victor Stinner.
- [bpo-13968](https://bugs.python.org/issue?@action=redirect&bpo=13968) [https://bugs.python.org/issue?@action=redirect&bpo=13968]: The glob module now supports recursive search in subdirectories using the \*\* pattern.
- [bpo-21951](https://bugs.python.org/issue?@action=redirect&bpo=21951) [https://bugs.python.org/issue?@action=redirect&bpo=21951]: Fixed a crash in Tkinter on AIX when called Tcl command with empty string or tuple argument.
- [bpo-21951](https://bugs.python.org/issue?@action=redirect&bpo=21951) [https://bugs.python.org/issue?@action=redirect&bpo=21951]: Tkinter now most likely raises MemoryError instead of crash if the memory allocation fails.
- [bpo-22338](https://bugs.python.org/issue?@action=redirect&bpo=22338) [https://bugs.python.org/issue?@action=redirect&bpo=22338]

@action=redirect&bpo=22338]: Fix a crash in the json module on memory allocation failure.

- [bpo-12410](https://bugs.python.org/issue?@action=redirect&bpo=12410) [https://bugs.python.org/issue?@action=redirect&bpo=12410]: imaplib.IMAP4 now supports the context management protocol. Original patch by Tarek Ziadé.
- [bpo-21270](https://bugs.python.org/issue?@action=redirect&bpo=21270) [https://bugs.python.org/issue?@action=redirect&bpo=21270]: We now override tuple methods in mock.call objects so that they can be used as normal call attributes.
- [bpo-16662](https://bugs.python.org/issue?@action=redirect&bpo=16662) [https://bugs.python.org/issue?@action=redirect&bpo=16662]: load\_tests() is now unconditionally run when it is present in a package's \_\_init\_\_.py. TestLoader.loadTestsFromModule() still accepts use load\_tests, but it is deprecated and ignored. A new keyword-only attribute **pattern** is added and documented. Patch given by Robert Collins, tweaked by Barry Warsaw.
- [bpo-22226](https://bugs.python.org/issue?@action=redirect&bpo=22226) [https://bugs.python.org/issue?@action=redirect&bpo=22226]: First letter no longer is stripped from the “status” key in the result of Treeview.heading().
- [bpo-19524](https://bugs.python.org/issue?@action=redirect&bpo=19524) [https://bugs.python.org/issue?@action=redirect&bpo=19524]: Fixed resource leak in the HTTP connection when an invalid response is received. Patch by Martin Panter.
- [bpo-20421](https://bugs.python.org/issue?@action=redirect&bpo=20421) [https://bugs.python.org/issue?@action=redirect&bpo=20421]: Add a .version() method to SSL sockets exposing the actual protocol version in use.
- [bpo-19546](https://bugs.python.org/issue?@action=redirect&bpo=19546) [https://bugs.python.org/issue?@action=redirect&bpo=19546]: configparser exceptions no longer expose implementation details. Chained KeyErrors are removed, which leads to cleaner tracebacks. Patch by Claudiu Popa.
- [bpo-22051](https://bugs.python.org/issue?@action=redirect&bpo=22051) [https://bugs.python.org/issue?@action=redirect&bpo=22051]: turtledemo no longer reloads examples to re-run them. Initialization of variables and gui setup should be done in main(), which is called each time a demo is run, but not on import.
- [bpo-21933](https://bugs.python.org/issue?@action=redirect&bpo=21933) [https://bugs.python.org/issue?@action=redirect&bpo=21933]: Turtledemo users can change the code font size with a menu selection or control(command) ‘-’ or ‘+’ or control-mousewheel. Original patch by Lita Cho.

- **bpo-21597** [<https://bugs.python.org/issue?@action=redirect&bpo=21597>]: The separator between the `turtledemo` text pane and the drawing canvas can now be grabbed and dragged with a mouse. The code text pane can be widened to easily view or copy the full width of the text. The canvas can be widened on small screens. Original patches by Jan Kanis and Lita Cho.
- **bpo-18132** [<https://bugs.python.org/issue?@action=redirect&bpo=18132>]: `Turtledemo` buttons no longer disappear when the window is shrunk. Original patches by Jan Kanis and Lita Cho.
- **bpo-22043** [<https://bugs.python.org/issue?@action=redirect&bpo=22043>]: `time.monotonic()` is now always available. `threading.Lock.acquire()`, `threading.RLock.acquire()` and socket operations now use a monotonic clock, instead of the system clock, when a timeout is used.
- **bpo-21527** [<https://bugs.python.org/issue?@action=redirect&bpo=21527>]: Add a default number of workers to `ThreadPoolExecutor` equal to 5 times the number of CPUs. Patch by Claudiu Popa.
- **bpo-22216** [<https://bugs.python.org/issue?@action=redirect&bpo=22216>]: `smtpplib` now resets its state more completely after a quit. The most obvious consequence of the previous behavior was a `STARTTLS` failure during a `connect/starttls/quit/connect/starttls` sequence.
- **bpo-22098** [<https://bugs.python.org/issue?@action=redirect&bpo=22098>]: `ctypes`' `BigEndianStructure` and `LittleEndianStructure` now define an empty `_slots_` so that subclasses don't always get an instance dict. Patch by Claudiu Popa.
- **bpo-22185** [<https://bugs.python.org/issue?@action=redirect&bpo=22185>]: Fix an occasional `RuntimeError` in `threading.Condition.wait()` caused by mutation of the waiters queue without holding the lock. Patch by Doug Zongker.
- **bpo-22287** [<https://bugs.python.org/issue?@action=redirect&bpo=22287>]: On UNIX, `_PyTime_gettimeofday()` now uses `clock_gettime(CLOCK_REALTIME)` if available. As a side effect, Python now depends on the `librt` library on Solaris and on Linux (only with `glibc` older than 2.17).

- [bpo-22182](https://bugs.python.org/issue?@action=redirect&bpo=22182) [https://bugs.python.org/issue?@action=redirect&bpo=22182]: Use `e.args` to unpack exceptions correctly in `distutils.file_util.move_file`. Patch by Claudiu Popa.
- The webbrowser module now uses subprocess's `start_new_session=True` rather than a potentially risky `preexec_fn=os.setsid` call.
- [bpo-22042](https://bugs.python.org/issue?@action=redirect&bpo=22042) [https://bugs.python.org/issue?@action=redirect&bpo=22042]: `signal.set_wakeup_fd(fd)` now raises an exception if the file descriptor is in blocking mode.
- [bpo-16808](https://bugs.python.org/issue?@action=redirect&bpo=16808) [https://bugs.python.org/issue?@action=redirect&bpo=16808]: `inspect.stack()` now returns a named tuple instead of a tuple. Patch by Daniel Shahaf.
- [bpo-22236](https://bugs.python.org/issue?@action=redirect&bpo=22236) [https://bugs.python.org/issue?@action=redirect&bpo=22236]: Fixed Tkinter images copying operations in `NoDefaultRoot` mode.
- [bpo-2527](https://bugs.python.org/issue?@action=redirect&bpo=2527) [https://bugs.python.org/issue?@action=redirect&bpo=2527]: Add a `globals` argument to `timeit` functions, in order to override the `globals` namespace in which the timed code is executed. Patch by Ben Roberts.
- [bpo-22118](https://bugs.python.org/issue?@action=redirect&bpo=22118) [https://bugs.python.org/issue?@action=redirect&bpo=22118]: Switch `urllib.parse` to use RFC 3986 semantics for the resolution of relative URLs, rather than RFCs 1808 and 2396. Patch by Demian Brecht.
- [bpo-21549](https://bugs.python.org/issue?@action=redirect&bpo=21549) [https://bugs.python.org/issue?@action=redirect&bpo=21549]: Added the “members” parameter to `TarFile.list()`.
- [bpo-19628](https://bugs.python.org/issue?@action=redirect&bpo=19628) [https://bugs.python.org/issue?@action=redirect&bpo=19628]: Allow `compileall` recursion depth to be specified with a `-r` option.
- [bpo-15696](https://bugs.python.org/issue?@action=redirect&bpo=15696) [https://bugs.python.org/issue?@action=redirect&bpo=15696]: Add a `__sizeof__` implementation for `mmap` objects on Windows.
- [bpo-22068](https://bugs.python.org/issue?@action=redirect&bpo=22068) [https://bugs.python.org/issue?@action=redirect&bpo=22068]: Avoided reference loops with Variables and Fonts in Tkinter.
- [bpo-22165](https://bugs.python.org/issue?@action=redirect&bpo=22165) [https://bugs.python.org/issue?@action=redirect&bpo=22165]: `SimpleHTTPRequestHandler` now supports undecodable file names.
- [bpo-15381](https://bugs.python.org/issue?@action=redirect&bpo=15381) [https://bugs.python.org/issue?@action=redirect&bpo=15381]

@action=redirect&bpo=15381]: Optimized line reading in io.BytesIO.

- [bpo-8797](https://bugs.python.org/issue?@action=redirect&bpo=8797) [https://bugs.python.org/issue?@action=redirect&bpo=8797]: Raise HTTPError on failed Basic Authentication immediately. Initial patch by Sam Bull.
- [bpo-20729](https://bugs.python.org/issue?@action=redirect&bpo=20729) [https://bugs.python.org/issue?@action=redirect&bpo=20729]: Restored the use of lazy iterkeys()/itervalues()/iteritems() in the mailbox module.
- [bpo-21448](https://bugs.python.org/issue?@action=redirect&bpo=21448) [https://bugs.python.org/issue?@action=redirect&bpo=21448]: Changed FeedParser feed() to avoid O(N<sup>2</sup>) behavior when parsing long line. Original patch by Raymond Hettinger.
- [bpo-22184](https://bugs.python.org/issue?@action=redirect&bpo=22184) [https://bugs.python.org/issue?@action=redirect&bpo=22184]: The functools LRU Cache decorator factory now gives an earlier and clearer error message when the user forgets the required parameters.
- [bpo-17923](https://bugs.python.org/issue?@action=redirect&bpo=17923) [https://bugs.python.org/issue?@action=redirect&bpo=17923]: glob() patterns ending with a slash no longer match non-dirs on AIX. Based on patch by Delhallt.
- [bpo-21725](https://bugs.python.org/issue?@action=redirect&bpo=21725) [https://bugs.python.org/issue?@action=redirect&bpo=21725]: Added support for RFC 6531 (SMTPUTF8) in smtpd.
- [bpo-22176](https://bugs.python.org/issue?@action=redirect&bpo=22176) [https://bugs.python.org/issue?@action=redirect&bpo=22176]: Update the ctypes module's libffi to v3.1. This release adds support for the Linux AArch64 and POWERPC ELF ABIv2 little endian architectures.
- [bpo-5411](https://bugs.python.org/issue?@action=redirect&bpo=5411) [https://bugs.python.org/issue?@action=redirect&bpo=5411]: Added support for the "xzstar" format in the shutil module.
- [bpo-21121](https://bugs.python.org/issue?@action=redirect&bpo=21121) [https://bugs.python.org/issue?@action=redirect&bpo=21121]: Don't force 3rd party C extensions to be built with -Werror=declaration-after-statement.
- [bpo-21975](https://bugs.python.org/issue?@action=redirect&bpo=21975) [https://bugs.python.org/issue?@action=redirect&bpo=21975]: Fixed crash when using uninitialized sqlite3.Row (in particular when unpickling pickled sqlite3.Row). sqlite3.Row is now initialized in the \_\_new\_\_() method.
- [bpo-20170](https://bugs.python.org/issue?@action=redirect&bpo=20170) [https://bugs.python.org/issue?@action=redirect&bpo=20170]: Convert posixmodule to use Argument Clinic.

- [bpo-21539](https://bugs.python.org/issue?@action=redirect&bpo=21539) [https://bugs.python.org/issue?@action=redirect&bpo=21539]: Add an *exists\_ok* argument to **Pathlib.mkdir()** to mimic **mkdir -p** and **os.makedirs()** functionality. When true, ignore FileExistsErrors. Patch by Berker Peksag.
- [bpo-22127](https://bugs.python.org/issue?@action=redirect&bpo=22127) [https://bugs.python.org/issue?@action=redirect&bpo=22127]: Bypass IDNA for pure-ASCII host names in the socket module (in particular for numeric IPs).
- [bpo-21047](https://bugs.python.org/issue?@action=redirect&bpo=21047) [https://bugs.python.org/issue?@action=redirect&bpo=21047]: set the default value for the *convert\_charrefs* argument of HTMLParser to True. Patch by Berker Peksag.
- Add an `_all_` to `html.entities`.
- [bpo-15114](https://bugs.python.org/issue?@action=redirect&bpo=15114) [https://bugs.python.org/issue?@action=redirect&bpo=15114]: the strict mode and argument of HTMLParser, HTMLParser.error, and the HTMLParserError exception have been removed.
- [bpo-22085](https://bugs.python.org/issue?@action=redirect&bpo=22085) [https://bugs.python.org/issue?@action=redirect&bpo=22085]: Dropped support of Tk 8.3 in Tkinter.
- [bpo-21580](https://bugs.python.org/issue?@action=redirect&bpo=21580) [https://bugs.python.org/issue?@action=redirect&bpo=21580]: Now Tkinter correctly handles bytes arguments passed to Tk. In particular this allows initializing images from binary data.
- [bpo-22003](https://bugs.python.org/issue?@action=redirect&bpo=22003) [https://bugs.python.org/issue?@action=redirect&bpo=22003]: When initialized from a bytes object, `io.BytesIO()` now defers making a copy until it is mutated, improving performance and memory use on some use cases. Patch by David Wilson.
- [bpo-22018](https://bugs.python.org/issue?@action=redirect&bpo=22018) [https://bugs.python.org/issue?@action=redirect&bpo=22018]: On Windows, `signal.set_wakeup_fd()` now also supports sockets. A side effect is that Python depends to the WinSock library.
- [bpo-22054](https://bugs.python.org/issue?@action=redirect&bpo=22054) [https://bugs.python.org/issue?@action=redirect&bpo=22054]: Add `os.get_blocking()` and `os.set_blocking()` functions to get and set the blocking mode of a file descriptor (False if the `O_NONBLOCK` flag is set, True otherwise). These functions are not available on Windows.
- [bpo-17172](https://bugs.python.org/issue?@action=redirect&bpo=17172) [https://bugs.python.org/issue?@action=redirect&bpo=17172]: Make `turtledemo` start as active

on OS X even when run with subprocess. Patch by Lita Cho.

- [bpo-21704](https://bugs.python.org/issue?@action=redirect&bpo=21704) [https://bugs.python.org/issue?@action=redirect&bpo=21704]: Fix build error for `_multiprocessing` when semaphores are not available. Patch by Arfrever Frehtes Taifersar Arahesis.
- [bpo-20173](https://bugs.python.org/issue?@action=redirect&bpo=20173) [https://bugs.python.org/issue?@action=redirect&bpo=20173]: Convert sha1, sha256, sha512 and md5 to `ArgumentClinic`. Patch by Vajrasky Kok.
- Fix `repr(socket.socket)` on Windows 64-bit: don't fail with `OverflowError` on closed socket. `repr(socket.socket)` already works fine.
- [bpo-22033](https://bugs.python.org/issue?@action=redirect&bpo=22033) [https://bugs.python.org/issue?@action=redirect&bpo=22033]: Reprs of most Python implemented classes now contain actual class name instead of hardcoded one.
- [bpo-21947](https://bugs.python.org/issue?@action=redirect&bpo=21947) [https://bugs.python.org/issue?@action=redirect&bpo=21947]: The `dis` module can now disassemble generator-iterator objects based on their `gi_code` attribute. Patch by Clement Rouault.
- [bpo-16133](https://bugs.python.org/issue?@action=redirect&bpo=16133) [https://bugs.python.org/issue?@action=redirect&bpo=16133]: The `asyncat.async_chat.handle_read()` method now ignores `BlockingIOError` exceptions.
- [bpo-22044](https://bugs.python.org/issue?@action=redirect&bpo=22044) [https://bugs.python.org/issue?@action=redirect&bpo=22044]: Fixed premature `DECREF` in `call_tzinfo_method`. Patch by Tom Flanagan.
- [bpo-19884](https://bugs.python.org/issue?@action=redirect&bpo=19884) [https://bugs.python.org/issue?@action=redirect&bpo=19884]: `readline`: Disable the meta modifier key if stdout is not a terminal to not write the ANSI sequence `"\033[1034h"` into stdout. This sequence is used on some terminal (ex: `TERM=xterm-256color`) to enable support of 8 bit characters.
- [bpo-4350](https://bugs.python.org/issue?@action=redirect&bpo=4350) [https://bugs.python.org/issue?@action=redirect&bpo=4350]: Removed a number of out-of-dated and non-working for a long time Tkinter methods.
- [bpo-6167](https://bugs.python.org/issue?@action=redirect&bpo=6167) [https://bugs.python.org/issue?@action=redirect&bpo=6167]: `Scrollbar.activate()` now returns the name of active element if the argument is not specified. `Scrollbar.set()` now always accepts only 2 arguments.
- [bpo-15275](https://bugs.python.org/issue?@action=redirect&bpo=15275) [https://bugs.python.org/issue?@action=redirect&bpo=15275]

@action=redirect&bpo=15275]: Clean up and speed up the ntpath module.

- [bpo-21888](https://bugs.python.org/issue?@action=redirect&bpo=21888) [https://bugs.python.org/issue?@action=redirect&bpo=21888]: plistlib's load() and loads() now work if the fmt parameter is specified.
- [bpo-22032](https://bugs.python.org/issue?@action=redirect&bpo=22032) [https://bugs.python.org/issue?@action=redirect&bpo=22032]: \_\_qualname\_\_ instead of \_\_name\_\_ is now always used to format fully qualified class names of Python implemented classes.
- [bpo-22031](https://bugs.python.org/issue?@action=redirect&bpo=22031) [https://bugs.python.org/issue?@action=redirect&bpo=22031]: Reprs now always use hexadecimal format with the "0x" prefix when contain an id in form " at 0x...".
- [bpo-22018](https://bugs.python.org/issue?@action=redirect&bpo=22018) [https://bugs.python.org/issue?@action=redirect&bpo=22018]: signal.set\_wakeup\_fd() now raises an OSError instead of a ValueError on fstat() failure.
- [bpo-21044](https://bugs.python.org/issue?@action=redirect&bpo=21044) [https://bugs.python.org/issue?@action=redirect&bpo=21044]: tarfile.open() now handles fileobj with an integer 'name' attribute. Based on patch by Antoine Pietri.
- [bpo-21966](https://bugs.python.org/issue?@action=redirect&bpo=21966) [https://bugs.python.org/issue?@action=redirect&bpo=21966]: Respect -q command-line option when code module is ran.
- [bpo-19076](https://bugs.python.org/issue?@action=redirect&bpo=19076) [https://bugs.python.org/issue?@action=redirect&bpo=19076]: Don't pass the redundant 'file' argument to self.error().
- [bpo-16382](https://bugs.python.org/issue?@action=redirect&bpo=16382) [https://bugs.python.org/issue?@action=redirect&bpo=16382]: Improve exception message of warnings.warn() for bad category. Initial patch by Phil Elson.
- [bpo-21932](https://bugs.python.org/issue?@action=redirect&bpo=21932) [https://bugs.python.org/issue?@action=redirect&bpo=21932]: os.read() now uses a [Py\\_ssize\\_t\(\)](#) type instead of int for the size to support reading more than 2 GB at once. On Windows, the size is truncated to INT\_MAX. As any call to os.read(), the OS may read less bytes than the number of requested bytes.
- [bpo-21942](https://bugs.python.org/issue?@action=redirect&bpo=21942) [https://bugs.python.org/issue?@action=redirect&bpo=21942]: Fixed source file viewing in pydoc's server mode on Windows.
- [bpo-11259](https://bugs.python.org/issue?@action=redirect&bpo=11259) [https://bugs.python.org/issue?@action=redirect&bpo=11259]:

`asyncio.async_chat().set_terminator()` now raises a `ValueError` if the number of received bytes is negative.

- [bpo-12523](https://bugs.python.org/issue?@action=redirect&bpo=12523) [https://bugs.python.org/issue?@action=redirect&bpo=12523]: `asyncio.async_chat.push()` now raises a `TypeError` if it doesn't get a bytes string
- [bpo-21707](https://bugs.python.org/issue?@action=redirect&bpo=21707) [https://bugs.python.org/issue?@action=redirect&bpo=21707]: Add missing `kwonlyargcount` argument to `ModuleFinder.replace_paths_in_code()`.
- [bpo-20639](https://bugs.python.org/issue?@action=redirect&bpo=20639) [https://bugs.python.org/issue?@action=redirect&bpo=20639]: calling `Path.with_suffix("")` allows removing the suffix again. Patch by July Tikhonov.
- [bpo-21714](https://bugs.python.org/issue?@action=redirect&bpo=21714) [https://bugs.python.org/issue?@action=redirect&bpo=21714]: Disallow the construction of invalid paths using `Path.with_name()`. Original patch by Antony Lee.
- [bpo-15014](https://bugs.python.org/issue?@action=redirect&bpo=15014) [https://bugs.python.org/issue?@action=redirect&bpo=15014]: Added 'auth' method to `smtplib` to make implementing auth mechanisms simpler, and used it internally in the login method.
- [bpo-21151](https://bugs.python.org/issue?@action=redirect&bpo=21151) [https://bugs.python.org/issue?@action=redirect&bpo=21151]: Fixed a segfault in the `winreg` module when `None` is passed as a `REG_BINARY` value to `SetValueEx`. Patch by John Ehresman.
- [bpo-21090](https://bugs.python.org/issue?@action=redirect&bpo=21090) [https://bugs.python.org/issue?@action=redirect&bpo=21090]: `io.FileIO.readall()` does not ignore I/O errors anymore. Before, it ignored I/O errors if at least the first `C` call `read()` succeed.
- [bpo-5800](https://bugs.python.org/issue?@action=redirect&bpo=5800) [https://bugs.python.org/issue?@action=redirect&bpo=5800]: `headers` parameter of `wsgiref.headers.Headers` is now optional. Initial patch by Pablo Torres Navarrete and SilentGhost.
- [bpo-21781](https://bugs.python.org/issue?@action=redirect&bpo=21781) [https://bugs.python.org/issue?@action=redirect&bpo=21781]: `ssl.RAND_add()` now supports strings longer than 2 GB.
- [bpo-21679](https://bugs.python.org/issue?@action=redirect&bpo=21679) [https://bugs.python.org/issue?@action=redirect&bpo=21679]: Prevent extraneous `fstat()` calls during `open()`. Patch by Bohuslav Kabrda.
- [bpo-21863](https://bugs.python.org/issue?@action=redirect&bpo=21863) [https://bugs.python.org/issue?@action=redirect&bpo=21863]: `cProfile` now displays the module name of `C` extension functions, in addition to their own name.

- [bpo-11453](https://bugs.python.org/issue?@action=redirect&bpo=11453) [https://bugs.python.org/issue?@action=redirect&bpo=11453]: `asyncore`: emit a `ResourceWarning` when an unclosed `file_wrapper` object is destroyed. The destructor now closes the file if needed. The `close()` method can now be called twice: the second call does nothing.
- [bpo-21858](https://bugs.python.org/issue?@action=redirect&bpo=21858) [https://bugs.python.org/issue?@action=redirect&bpo=21858]: Better handling of Python exceptions in the `sqlite3` module.
- [bpo-21476](https://bugs.python.org/issue?@action=redirect&bpo=21476) [https://bugs.python.org/issue?@action=redirect&bpo=21476]: Make sure the `email.parser.BytesParser` `TextIOWrapper` is discarded after parsing, so the input file isn't unexpectedly closed.
- [bpo-20295](https://bugs.python.org/issue?@action=redirect&bpo=20295) [https://bugs.python.org/issue?@action=redirect&bpo=20295]: `imgchr` now recognizes `OpenEXR` format images.
- [bpo-21729](https://bugs.python.org/issue?@action=redirect&bpo=21729) [https://bugs.python.org/issue?@action=redirect&bpo=21729]: Used the "with" statement in the `dbm.dumb` module to ensure files closing. Patch by Claudiu Popa.
- [bpo-21491](https://bugs.python.org/issue?@action=redirect&bpo=21491) [https://bugs.python.org/issue?@action=redirect&bpo=21491]: `socketserver`: Fix a race condition in child processes reaping.
- [bpo-21719](https://bugs.python.org/issue?@action=redirect&bpo=21719) [https://bugs.python.org/issue?@action=redirect&bpo=21719]: Added the `st_file_attributes` field to `os.stat_result` on Windows.
- [bpo-21832](https://bugs.python.org/issue?@action=redirect&bpo=21832) [https://bugs.python.org/issue?@action=redirect&bpo=21832]: Require named tuple inputs to be exact strings.
- [bpo-21722](https://bugs.python.org/issue?@action=redirect&bpo=21722) [https://bugs.python.org/issue?@action=redirect&bpo=21722]: The `distutils` "upload" command now exits with a non-zero return code when uploading fails. Patch by Martin Dengler.
- [bpo-21723](https://bugs.python.org/issue?@action=redirect&bpo=21723) [https://bugs.python.org/issue?@action=redirect&bpo=21723]: `asyncio.Queue`: support any type of number (ex: float) for the maximum size. Patch written by Vajrasky Kok.
- [bpo-21711](https://bugs.python.org/issue?@action=redirect&bpo=21711) [https://bugs.python.org/issue?@action=redirect&bpo=21711]: support for "site-python" directories has now been removed from the `site` module (it

was deprecated in 3.4).

- [bpo-17552](https://bugs.python.org/issue?@action=redirect&bpo=17552) [https://bugs.python.org/issue?@action=redirect&bpo=17552]: new `socket.sendfile()` method allowing a file to be sent over a socket by using high-performance `os.sendfile()` on UNIX. Patch by Giampaolo Rodola’.
- [bpo-18039](https://bugs.python.org/issue?@action=redirect&bpo=18039) [https://bugs.python.org/issue?@action=redirect&bpo=18039]: `dbm.dump.open()` now always creates a new database when the flag has the value ‘n’. Patch by Claudiu Popa.
- [bpo-21326](https://bugs.python.org/issue?@action=redirect&bpo=21326) [https://bugs.python.org/issue?@action=redirect&bpo=21326]: Add a new `is_closed()` method to `asyncio.BaseEventLoop.run_forever()` and `run_until_complete()` methods of `asyncio.BaseEventLoop` now raise an exception if the event loop was closed.
- [bpo-21766](https://bugs.python.org/issue?@action=redirect&bpo=21766) [https://bugs.python.org/issue?@action=redirect&bpo=21766]: Prevent a security hole in `CGIHTTPServer` by URL unquoting paths before checking for a CGI script at that path.
- [bpo-21310](https://bugs.python.org/issue?@action=redirect&bpo=21310) [https://bugs.python.org/issue?@action=redirect&bpo=21310]: Fixed possible resource leak in `failed open()`.
- [bpo-21256](https://bugs.python.org/issue?@action=redirect&bpo=21256) [https://bugs.python.org/issue?@action=redirect&bpo=21256]: Printout of keyword args should be in deterministic order in a mock function call. This will help to write better doctests.
- [bpo-21677](https://bugs.python.org/issue?@action=redirect&bpo=21677) [https://bugs.python.org/issue?@action=redirect&bpo=21677]: Fixed chaining nonnormalized exceptions in `io.close()` methods.
- [bpo-11709](https://bugs.python.org/issue?@action=redirect&bpo=11709) [https://bugs.python.org/issue?@action=redirect&bpo=11709]: Fix the `pydoc.help` function to not fail when `sys.stdin` is not a valid file.
- [bpo-21515](https://bugs.python.org/issue?@action=redirect&bpo=21515) [https://bugs.python.org/issue?@action=redirect&bpo=21515]: `tempfile.TemporaryFile` now uses `os.O_TMPFILE` flag is available.
- [bpo-13223](https://bugs.python.org/issue?@action=redirect&bpo=13223) [https://bugs.python.org/issue?@action=redirect&bpo=13223]: Fix `pydoc.writedoc` so that the HTML documentation for methods that use ‘self’ in the example code is generated correctly.
- [bpo-21463](https://bugs.python.org/issue?@action=redirect&bpo=21463) [https://bugs.python.org/issue?@action=redirect&bpo=21463]

@action=redirect&bpo=21463]: In urllib.request, fix pruning of the FTP cache.

- [bpo-21618](https://bugs.python.org/issue?@action=redirect&bpo=21618) [https://bugs.python.org/issue?@action=redirect&bpo=21618]: The subprocess module could fail to close open fds that were inherited by the calling process and already higher than POSIX resource limits would otherwise allow. On systems with a functioning /proc/self/fd or /dev/fd interface the max is now ignored and all fds are closed.
- [bpo-20383](https://bugs.python.org/issue?@action=redirect&bpo=20383) [https://bugs.python.org/issue?@action=redirect&bpo=20383]: Introduce importlib.util.module\_from\_spec() as the preferred way to create a new module.
- [bpo-21552](https://bugs.python.org/issue?@action=redirect&bpo=21552) [https://bugs.python.org/issue?@action=redirect&bpo=21552]: Fixed possible integer overflow of too long string lengths in the tkinter module on 64-bit platforms.
- [bpo-14315](https://bugs.python.org/issue?@action=redirect&bpo=14315) [https://bugs.python.org/issue?@action=redirect&bpo=14315]: The zipfile module now ignores extra fields in the central directory that are too short to be parsed instead of letting a struct.unpack error bubble up as this “bad data” appears in many real world zip files in the wild and is ignored by other zip tools.
- [bpo-13742](https://bugs.python.org/issue?@action=redirect&bpo=13742) [https://bugs.python.org/issue?@action=redirect&bpo=13742]: Added “key” and “reverse” parameters to heapq.merge(). (First draft of patch contributed by Simon Sapin.)
- [bpo-21402](https://bugs.python.org/issue?@action=redirect&bpo=21402) [https://bugs.python.org/issue?@action=redirect&bpo=21402]: tkinter.ttk now works when default root window is not set.
- [bpo-3015](https://bugs.python.org/issue?@action=redirect&bpo=3015) [https://bugs.python.org/issue?@action=redirect&bpo=3015]: \_tkinter.create() now creates tkapp object with wantobject=1 by default.
- [bpo-10203](https://bugs.python.org/issue?@action=redirect&bpo=10203) [https://bugs.python.org/issue?@action=redirect&bpo=10203]: sqlite3.Row now truly supports sequence protocol. In particular it supports reverse() and negative indices. Original patch by Claudiu Popa.
- [bpo-18807](https://bugs.python.org/issue?@action=redirect&bpo=18807) [https://bugs.python.org/issue?@action=redirect&bpo=18807]: If copying (no symlinks) specified for a venv, then the python interpreter aliases (python,

python3) are now created by copying rather than symlinking.

- [bpo-20197](https://bugs.python.org/issue?@action=redirect&bpo=20197) [https://bugs.python.org/issue?@action=redirect&bpo=20197]: Added support for the WebP image type in the `imghdr` module. Patch by Fabrice Anecche and Claudiu Popa.
- [bpo-21513](https://bugs.python.org/issue?@action=redirect&bpo=21513) [https://bugs.python.org/issue?@action=redirect&bpo=21513]: Speedup some properties of IP addresses (`IPv4Address`, `IPv6Address`) such as `.is_private` or `.is_multicast`.
- [bpo-21137](https://bugs.python.org/issue?@action=redirect&bpo=21137) [https://bugs.python.org/issue?@action=redirect&bpo=21137]: Improve the repr for `threading.Lock()` and its variants by showing the “locked” or “unlocked” status. Patch by Berker Peksag.
- [bpo-21538](https://bugs.python.org/issue?@action=redirect&bpo=21538) [https://bugs.python.org/issue?@action=redirect&bpo=21538]: The `plistlib` module now supports loading of binary plist files when reference or offset size is not a power of two.
- [bpo-21455](https://bugs.python.org/issue?@action=redirect&bpo=21455) [https://bugs.python.org/issue?@action=redirect&bpo=21455]: Add a default backlog to `socket.listen()`.
- [bpo-21525](https://bugs.python.org/issue?@action=redirect&bpo=21525) [https://bugs.python.org/issue?@action=redirect&bpo=21525]: Most Tkinter methods which accepted tuples now accept lists too.
- [bpo-22166](https://bugs.python.org/issue?@action=redirect&bpo=22166) [https://bugs.python.org/issue?@action=redirect&bpo=22166]: With the assistance of a new internal `_codecs._forget_codec` helping function, `test_codecs` now clears the encoding caches to avoid the appearance of a reference leak
- [bpo-22236](https://bugs.python.org/issue?@action=redirect&bpo=22236) [https://bugs.python.org/issue?@action=redirect&bpo=22236]: Tkinter tests now don't reuse default root window. New root window is created for every test class.
- [bpo-10744](https://bugs.python.org/issue?@action=redirect&bpo=10744) [https://bugs.python.org/issue?@action=redirect&bpo=10744]: Fix [PEP 3118](https://peps.python.org/pep-3118/) [https://peps.python.org/pep-3118/] format strings on ctypes objects with a nontrivial shape.
- [bpo-20826](https://bugs.python.org/issue?@action=redirect&bpo=20826) [https://bugs.python.org/issue?@action=redirect&bpo=20826]: Optimize `ipaddress.collapse_addresses()`.
- [bpo-21487](https://bugs.python.org/issue?@action=redirect&bpo=21487) [https://bugs.python.org/issue?@action=redirect&bpo=21487]

@action=redirect&bpo=21487]: Optimize  
ipaddress.summarize\_address\_range() and ipaddress.  
{IPv4Network,IPv6Network}.subnets().

- [bpo-21486](https://bugs.python.org/issue?@action=redirect&bpo=21486) [https://bugs.python.org/issue?  
@action=redirect&bpo=21486]: Optimize parsing of netmasks in  
ipaddress.IPv4Network and ipaddress.IPv6Network.
- [bpo-13916](https://bugs.python.org/issue?@action=redirect&bpo=13916) [https://bugs.python.org/issue?  
@action=redirect&bpo=13916]: Disallowed the surrogatepass  
error handler for non UTF-\* encodings.
- [bpo-20998](https://bugs.python.org/issue?@action=redirect&bpo=20998) [https://bugs.python.org/issue?  
@action=redirect&bpo=20998]: Fixed re.fullmatch() of repeated  
single character pattern with ignore case. Original patch by  
Matthew Barnett.
- [bpo-21075](https://bugs.python.org/issue?@action=redirect&bpo=21075) [https://bugs.python.org/issue?  
@action=redirect&bpo=21075]: fileinput.FileInput now reads  
bytes from standard stream if binary mode is specified. Patch  
by Sam Kimbrel.
- [bpo-19775](https://bugs.python.org/issue?@action=redirect&bpo=19775) [https://bugs.python.org/issue?  
@action=redirect&bpo=19775]: Add a samefile() method to  
pathlib Path objects. Initial patch by Vajrasky Kok.
- [bpo-21226](https://bugs.python.org/issue?@action=redirect&bpo=21226) [https://bugs.python.org/issue?  
@action=redirect&bpo=21226]: Set up modules properly in  
PyImport\_ExecCodeModuleObject (and friends).
- [bpo-21398](https://bugs.python.org/issue?@action=redirect&bpo=21398) [https://bugs.python.org/issue?  
@action=redirect&bpo=21398]: Fix a unicode error in the pydoc  
pager when the documentation contains characters not  
encodable to the stdout encoding.
- [bpo-16531](https://bugs.python.org/issue?@action=redirect&bpo=16531) [https://bugs.python.org/issue?  
@action=redirect&bpo=16531]: ipaddress.IPv4Network and  
ipaddress.IPv6Network now accept an (address, netmask)  
tuple argument, so as to easily construct network objects from  
existing addresses.
- [bpo-21156](https://bugs.python.org/issue?@action=redirect&bpo=21156) [https://bugs.python.org/issue?  
@action=redirect&bpo=21156]:  
importlib.abc.InspectLoader.source\_to\_code() is now a  
staticmethod.
- [bpo-21424](https://bugs.python.org/issue?@action=redirect&bpo=21424) [https://bugs.python.org/issue?  
@action=redirect&bpo=21424]: Simplified and optimized  
heapq.nlargest() and nsmallest() to make fewer tuple  
comparisons.

- [bpo-21396](https://bugs.python.org/issue?@action=redirect&bpo=21396) [https://bugs.python.org/issue?@action=redirect&bpo=21396]: Fix `TextIOWrapper(..., write_through=True)` to not force a `flush()` on the underlying binary stream. Patch by akira.
- [bpo-18314](https://bugs.python.org/issue?@action=redirect&bpo=18314) [https://bugs.python.org/issue?@action=redirect&bpo=18314]: Unlink now removes junctions on Windows. Patch by Kim Gräsman
- [bpo-21088](https://bugs.python.org/issue?@action=redirect&bpo=21088) [https://bugs.python.org/issue?@action=redirect&bpo=21088]: Bugfix for `curses.window.addch()` regression in 3.4.0. In porting to Argument Clinic, the first two arguments were reversed.
- [bpo-21407](https://bugs.python.org/issue?@action=redirect&bpo=21407) [https://bugs.python.org/issue?@action=redirect&bpo=21407]: `_decimal`: The module now supports function signatures.
- [bpo-10650](https://bugs.python.org/issue?@action=redirect&bpo=10650) [https://bugs.python.org/issue?@action=redirect&bpo=10650]: Remove the non-standard ‘`watchexp`’ parameter from the `Decimal.quantize()` method in the Python version. It had never been present in the C version.
- [bpo-21469](https://bugs.python.org/issue?@action=redirect&bpo=21469) [https://bugs.python.org/issue?@action=redirect&bpo=21469]: Reduced the risk of false positives in `robotparser` by checking to make sure that `robots.txt` has been read or does not exist prior to returning `True` in `can_fetch()`.
- [bpo-19414](https://bugs.python.org/issue?@action=redirect&bpo=19414) [https://bugs.python.org/issue?@action=redirect&bpo=19414]: Have the `OrderedDict` mark deleted links as unusable. This gives an early failure if the link is deleted during iteration.
- [bpo-21421](https://bugs.python.org/issue?@action=redirect&bpo=21421) [https://bugs.python.org/issue?@action=redirect&bpo=21421]: Add `_slots_` to the `MappingViews` ABC. Patch by Josh Rosenberg.
- [bpo-21101](https://bugs.python.org/issue?@action=redirect&bpo=21101) [https://bugs.python.org/issue?@action=redirect&bpo=21101]: Eliminate double hashing in the C speed-up code for `collections.Counter()`.
- [bpo-21321](https://bugs.python.org/issue?@action=redirect&bpo=21321) [https://bugs.python.org/issue?@action=redirect&bpo=21321]: `itertools.islice()` now releases the reference to the source iterator when the slice is exhausted. Patch by Anton Afanasyev.
- [bpo-21057](https://bugs.python.org/issue?@action=redirect&bpo=21057) [https://bugs.python.org/issue?@action=redirect&bpo=21057]: `TextIOWrapper` now allows the

underlying binary stream's `read()` or `read1()` method to return an arbitrary bytes-like object (such as a `memoryview`). Patch by Nikolaus Rath.

- [bpo-20951](https://bugs.python.org/issue?@action=redirect&bpo=20951) [https://bugs.python.org/issue?@action=redirect&bpo=20951]: `SSLSocket.send()` now raises either `SSLWantReadError` or `SSLWantWriteError` on a non-blocking socket if the operation would block. Previously, it would return 0. Patch by Nikolaus Rath.
- [bpo-13248](https://bugs.python.org/issue?@action=redirect&bpo=13248) [https://bugs.python.org/issue?@action=redirect&bpo=13248]: removed previously deprecated `asyncore.dispatcher __getattr__` cheap inheritance hack.
- [bpo-9815](https://bugs.python.org/issue?@action=redirect&bpo=9815) [https://bugs.python.org/issue?@action=redirect&bpo=9815]: `assertRaises` now tries to clear references to local variables in the exception's traceback.
- [bpo-19940](https://bugs.python.org/issue?@action=redirect&bpo=19940) [https://bugs.python.org/issue?@action=redirect&bpo=19940]: `ssl.cert_time_to_seconds()` now interprets the given time string in the UTC timezone (as specified in RFC 5280), not the local timezone.
- [bpo-13204](https://bugs.python.org/issue?@action=redirect&bpo=13204) [https://bugs.python.org/issue?@action=redirect&bpo=13204]: Calling `sys.flags._new_` would crash the interpreter, now it raises a `TypeError`.
- [bpo-19385](https://bugs.python.org/issue?@action=redirect&bpo=19385) [https://bugs.python.org/issue?@action=redirect&bpo=19385]: Make operations on a closed `dbm.dumb` database always raise the same exception.
- [bpo-21207](https://bugs.python.org/issue?@action=redirect&bpo=21207) [https://bugs.python.org/issue?@action=redirect&bpo=21207]: Detect when the `os.urandom` cached fd has been closed or replaced, and open it anew.
- [bpo-21291](https://bugs.python.org/issue?@action=redirect&bpo=21291) [https://bugs.python.org/issue?@action=redirect&bpo=21291]: `subprocess's Popen.wait()` is now thread safe so that multiple threads may be calling `wait()` or `poll()` on a `Popen` instance at the same time without losing the `Popen.returncode` value.
- [bpo-21127](https://bugs.python.org/issue?@action=redirect&bpo=21127) [https://bugs.python.org/issue?@action=redirect&bpo=21127]: `Path` objects can now be instantiated from `str` subclass instances (such as `numpy.str_`).
- [bpo-15002](https://bugs.python.org/issue?@action=redirect&bpo=15002) [https://bugs.python.org/issue?@action=redirect&bpo=15002]: `urllib.response` object to use `_TemporaryFileWrapper` (and `_TemporaryFileCloser`) facility. Provides a better way to handle file descriptor close. Patch

contributed by Christian Theune.

- [bpo-12220](https://bugs.python.org/issue?@action=redirect&bpo=12220) [https://bugs.python.org/issue?@action=redirect&bpo=12220]: `mindom` now raises a custom `ValueError` indicating it doesn't support spaces in URIs instead of letting a 'split' `ValueError` bubble up.
- [bpo-21068](https://bugs.python.org/issue?@action=redirect&bpo=21068) [https://bugs.python.org/issue?@action=redirect&bpo=21068]: The `ssl.PROTOCOL*` constants are now enum members.
- [bpo-21276](https://bugs.python.org/issue?@action=redirect&bpo=21276) [https://bugs.python.org/issue?@action=redirect&bpo=21276]: `posixmodule`: Don't define `USE_XATTRS` on `KFreeBSD` and the `Hurd`.
- [bpo-21262](https://bugs.python.org/issue?@action=redirect&bpo=21262) [https://bugs.python.org/issue?@action=redirect&bpo=21262]: New method `assert_not_called` for `Mock`. It raises `AssertionError` if the mock has been called.
- [bpo-21238](https://bugs.python.org/issue?@action=redirect&bpo=21238) [https://bugs.python.org/issue?@action=redirect&bpo=21238]: New keyword argument `unsafe` to `Mock`. It raises `AttributeError` in case of an attribute start with `assert` or `assert`.
- [bpo-20896](https://bugs.python.org/issue?@action=redirect&bpo=20896) [https://bugs.python.org/issue?@action=redirect&bpo=20896]: `ssl.get_server_certificate()` now uses `PROTOCOL_SSLv23`, not `PROTOCOL_SSLv3`, for maximum compatibility.
- [bpo-21239](https://bugs.python.org/issue?@action=redirect&bpo=21239) [https://bugs.python.org/issue?@action=redirect&bpo=21239]: `patch.stopall()` didn't work deterministically when the same name was patched more than once.
- [bpo-21203](https://bugs.python.org/issue?@action=redirect&bpo=21203) [https://bugs.python.org/issue?@action=redirect&bpo=21203]: Updated `fileConfig` and `dictConfig` to remove inconsistencies. Thanks to Jure Koren for the patch.
- [bpo-21222](https://bugs.python.org/issue?@action=redirect&bpo=21222) [https://bugs.python.org/issue?@action=redirect&bpo=21222]: Passing name keyword argument to `mock.create_autospec` now works.
- [bpo-21197](https://bugs.python.org/issue?@action=redirect&bpo=21197) [https://bugs.python.org/issue?@action=redirect&bpo=21197]: Add `lib64` -> `lib` symlink in `venvs` on 64-bit non-OS X POSIX.
- [bpo-17498](https://bugs.python.org/issue?@action=redirect&bpo=17498) [https://bugs.python.org/issue?@action=redirect&bpo=17498]: Some SMTP servers disconnect after certain errors, violating strict RFC conformance. Instead of losing the error code when we issue the subsequent `RSET`,

smtplib now returns the error code and defers raising the SMTPServerDisconnected error until the next command is issued.

- [bpo-17826](https://bugs.python.org/issue?@action=redirect&bpo=17826) [https://bugs.python.org/issue?@action=redirect&bpo=17826]: setting an iterable side\_effect on a mock function created by create\_autospec now works. Patch by Kushal Das.
- [bpo-7776](https://bugs.python.org/issue?@action=redirect&bpo=7776) [https://bugs.python.org/issue?@action=redirect&bpo=7776]: Fix Host: header and reconnection when using http.client.HTTPConnection.set\_tunnel(). Patch by Nikolaus Rath.
- [bpo-20968](https://bugs.python.org/issue?@action=redirect&bpo=20968) [https://bugs.python.org/issue?@action=redirect&bpo=20968]: unittest.mock.MagicMock now supports division. Patch by Johannes Baiter.
- [bpo-21529](https://bugs.python.org/issue?@action=redirect&bpo=21529) [https://bugs.python.org/issue?@action=redirect&bpo=21529]: Fix arbitrary memory access in JSONDecoder.raw\_decode with a negative second parameter. Bug reported by Guido Vranken. (See also: CVE-2014-4616)
- [bpo-21169](https://bugs.python.org/issue?@action=redirect&bpo=21169) [https://bugs.python.org/issue?@action=redirect&bpo=21169]: getpass now handles non-ascii characters that the input stream encoding cannot encode by re-encoding using the replace error handler.
- [bpo-21171](https://bugs.python.org/issue?@action=redirect&bpo=21171) [https://bugs.python.org/issue?@action=redirect&bpo=21171]: Fixed undocumented filter API of the rot13 codec. Patch by Berker Peksag.
- [bpo-20539](https://bugs.python.org/issue?@action=redirect&bpo=20539) [https://bugs.python.org/issue?@action=redirect&bpo=20539]: Improved math.factorial error message for large positive inputs and changed exception type (OverflowError -> ValueError) for large negative inputs.
- [bpo-21172](https://bugs.python.org/issue?@action=redirect&bpo=21172) [https://bugs.python.org/issue?@action=redirect&bpo=21172]: isinstance check relaxed from dict to collections.Mapping.
- [bpo-21155](https://bugs.python.org/issue?@action=redirect&bpo=21155) [https://bugs.python.org/issue?@action=redirect&bpo=21155]: asyncio.EventLoop.create\_unix\_server() now raises a ValueError if path and sock are specified at the same time.
- [bpo-21136](https://bugs.python.org/issue?@action=redirect&bpo=21136) [https://bugs.python.org/issue?@action=redirect&bpo=21136]: Avoid unnecessary normalization of Fractions resulting from power and other operations. Patch by Raymond Hettinger.

- [bpo-17621](https://bugs.python.org/issue?@action=redirect&bpo=17621) [https://bugs.python.org/issue?@action=redirect&bpo=17621]: Introduce `importlib.util.LazyLoader`.
- [bpo-21076](https://bugs.python.org/issue?@action=redirect&bpo=21076) [https://bugs.python.org/issue?@action=redirect&bpo=21076]: signal module constants were turned into enums. Patch by Giampaolo Rodola’.
- [bpo-20636](https://bugs.python.org/issue?@action=redirect&bpo=20636) [https://bugs.python.org/issue?@action=redirect&bpo=20636]: Improved the repr of Tkinter widgets.
- [bpo-19505](https://bugs.python.org/issue?@action=redirect&bpo=19505) [https://bugs.python.org/issue?@action=redirect&bpo=19505]: The items, keys, and values views of `OrderedDict` now support reverse iteration using `reversed()`.
- [bpo-21149](https://bugs.python.org/issue?@action=redirect&bpo=21149) [https://bugs.python.org/issue?@action=redirect&bpo=21149]: Improved thread-safety in logging cleanup during interpreter shutdown. Thanks to Devin Jeanpierre for the patch.
- [bpo-21058](https://bugs.python.org/issue?@action=redirect&bpo=21058) [https://bugs.python.org/issue?@action=redirect&bpo=21058]: Fix a leak of file descriptor in `tempfile.NamedTemporaryFile()`, close the file descriptor if `io.open()` fails
- [bpo-21200](https://bugs.python.org/issue?@action=redirect&bpo=21200) [https://bugs.python.org/issue?@action=redirect&bpo=21200]: Return `None` from `pkgutil.get_loader()` when `__spec__` is missing.
- [bpo-21013](https://bugs.python.org/issue?@action=redirect&bpo=21013) [https://bugs.python.org/issue?@action=redirect&bpo=21013]: Enhance `ssl.create_default_context()` when used for server side sockets to provide better security by default.
- [bpo-20145](https://bugs.python.org/issue?@action=redirect&bpo=20145) [https://bugs.python.org/issue?@action=redirect&bpo=20145]: **`assertRaisesRegex`** and **`assertWarnsRegex`** now raise a `TypeError` if the second argument is not a string or compiled regex.
- [bpo-20633](https://bugs.python.org/issue?@action=redirect&bpo=20633) [https://bugs.python.org/issue?@action=redirect&bpo=20633]: Replace relative import by absolute import.
- [bpo-20980](https://bugs.python.org/issue?@action=redirect&bpo=20980) [https://bugs.python.org/issue?@action=redirect&bpo=20980]: Stop wrapping exception when using `ThreadPool`.
- [bpo-21082](https://bugs.python.org/issue?@action=redirect&bpo=21082) [https://bugs.python.org/issue?@action=redirect&bpo=21082]: In `os.makedirs`, do not set the

process-wide umask. Note this changes behavior of `makedirs` when `exist_ok = True`.

- [bpo-20990](https://bugs.python.org/issue?@action=redirect&bpo=20990) [https://bugs.python.org/issue?@action=redirect&bpo=20990]: Fix issues found by pyflakes for multiprocessing.
- [bpo-21015](https://bugs.python.org/issue?@action=redirect&bpo=21015) [https://bugs.python.org/issue?@action=redirect&bpo=21015]: SSL contexts will now automatically select an elliptic curve for ECDH key exchange on OpenSSL 1.0.2 and later, and otherwise default to “prime256v1”.
- [bpo-21000](https://bugs.python.org/issue?@action=redirect&bpo=21000) [https://bugs.python.org/issue?@action=redirect&bpo=21000]: Improve the command-line interface of `json.tool`.
- [bpo-20995](https://bugs.python.org/issue?@action=redirect&bpo=20995) [https://bugs.python.org/issue?@action=redirect&bpo=20995]: Enhance default ciphers used by the `ssl` module to enable better security and prioritize perfect forward secrecy.
- [bpo-20884](https://bugs.python.org/issue?@action=redirect&bpo=20884) [https://bugs.python.org/issue?@action=redirect&bpo=20884]: Don’t assume that `_file_` is defined on `importlib._init_`.
- [bpo-21499](https://bugs.python.org/issue?@action=redirect&bpo=21499) [https://bugs.python.org/issue?@action=redirect&bpo=21499]: Ignore `_builtins_` in several `test_importlib.test_api` tests.
- [bpo-20627](https://bugs.python.org/issue?@action=redirect&bpo=20627) [https://bugs.python.org/issue?@action=redirect&bpo=20627]: `xmlrpc.client.ServerProxy` is now a context manager.
- [bpo-19165](https://bugs.python.org/issue?@action=redirect&bpo=19165) [https://bugs.python.org/issue?@action=redirect&bpo=19165]: The formatter module now raises `DeprecationWarning` instead of `PendingDeprecationWarning`.
- [bpo-13936](https://bugs.python.org/issue?@action=redirect&bpo=13936) [https://bugs.python.org/issue?@action=redirect&bpo=13936]: Remove the ability of `datetime.time` instances to be considered false in boolean contexts.
- [bpo-18931](https://bugs.python.org/issue?@action=redirect&bpo=18931) [https://bugs.python.org/issue?@action=redirect&bpo=18931]: selectors module now supports /dev/poll on Solaris. Patch by Giampaolo Rodola’.
- [bpo-19977](https://bugs.python.org/issue?@action=redirect&bpo=19977) [https://bugs.python.org/issue?@action=redirect&bpo=19977]: When the `LC_TYPE` locale is the POSIX locale (C locale), `sys.stdin` and `sys.stdout` are now using the `surrogateescape` error handler, instead of

the `strict` error handler.

- [bpo-20574](https://bugs.python.org/issue?@action=redirect&bpo=20574) [https://bugs.python.org/issue?@action=redirect&bpo=20574]: Implement incremental decoder for cp65001 code (Windows code page 65001, Microsoft UTF-8).
- [bpo-20879](https://bugs.python.org/issue?@action=redirect&bpo=20879) [https://bugs.python.org/issue?@action=redirect&bpo=20879]: Delay the initialization of encoding and decoding tables for base32, ascii85 and base85 codecs in the base64 module, and delay the initialization of the `unquote_to_bytes()` table of the `urllib.parse` module, to not waste memory if these modules are not used.
- [bpo-19157](https://bugs.python.org/issue?@action=redirect&bpo=19157) [https://bugs.python.org/issue?@action=redirect&bpo=19157]: Include the broadcast address in the usable hosts for IPv6 in `ipaddress`.
- [bpo-11599](https://bugs.python.org/issue?@action=redirect&bpo=11599) [https://bugs.python.org/issue?@action=redirect&bpo=11599]: When an external command (e.g. compiler) fails, `distutils` now prints out the whole command line (instead of just the command name) if the environment variable `DISTUTILS_DEBUG` is set.
- [bpo-4931](https://bugs.python.org/issue?@action=redirect&bpo=4931) [https://bugs.python.org/issue?@action=redirect&bpo=4931]: `distutils` should not produce unhelpful “error: None” messages anymore. `distutils.util.grok_environment_error` is kept but doc-deprecated.
- [bpo-20875](https://bugs.python.org/issue?@action=redirect&bpo=20875) [https://bugs.python.org/issue?@action=redirect&bpo=20875]: Prevent possible gzip “‘read’ is not defined” `NameError`. Patch by Claudiu Popa.
- [bpo-11558](https://bugs.python.org/issue?@action=redirect&bpo=11558) [https://bugs.python.org/issue?@action=redirect&bpo=11558]: `email.message.Message.attach` now returns a more useful error message if `attach` is called on a message for which `is_multipart` is `False`.
- [bpo-20283](https://bugs.python.org/issue?@action=redirect&bpo=20283) [https://bugs.python.org/issue?@action=redirect&bpo=20283]: `RE` pattern methods now accept the string keyword parameters as documented. The pattern and source keyword parameters are left as deprecated aliases.
- [bpo-20778](https://bugs.python.org/issue?@action=redirect&bpo=20778) [https://bugs.python.org/issue?@action=redirect&bpo=20778]: Fix `modulefinder` to work with bytecode-only modules.
- [bpo-20791](https://bugs.python.org/issue?@action=redirect&bpo=20791) [https://bugs.python.org/issue?@action=redirect&bpo=20791]: `copy.copy()` now doesn’t make a

copy when the input is a bytes object. Initial patch by Peter Otten.

- [bpo-19748](https://bugs.python.org/issue?@action=redirect&bpo=19748) [https://bugs.python.org/issue?@action=redirect&bpo=19748]: On AIX, time.mktime() now raises an OverflowError for year outsize range [1902; 2037].
- [bpo-19573](https://bugs.python.org/issue?@action=redirect&bpo=19573) [https://bugs.python.org/issue?@action=redirect&bpo=19573]: inspect.signature: Use enum for parameter kind constants.
- [bpo-20726](https://bugs.python.org/issue?@action=redirect&bpo=20726) [https://bugs.python.org/issue?@action=redirect&bpo=20726]: inspect.signature: Make Signature and Parameter picklable.
- [bpo-17373](https://bugs.python.org/issue?@action=redirect&bpo=17373) [https://bugs.python.org/issue?@action=redirect&bpo=17373]: Add inspect.Signature.from\_callable method.
- [bpo-20378](https://bugs.python.org/issue?@action=redirect&bpo=20378) [https://bugs.python.org/issue?@action=redirect&bpo=20378]: Improve repr of inspect.Signature and inspect.Parameter.
- [bpo-20816](https://bugs.python.org/issue?@action=redirect&bpo=20816) [https://bugs.python.org/issue?@action=redirect&bpo=20816]: Fix inspect.getcallargs() to raise correct TypeError for missing keyword-only arguments. Patch by Jeremiah Lowin.
- [bpo-20817](https://bugs.python.org/issue?@action=redirect&bpo=20817) [https://bugs.python.org/issue?@action=redirect&bpo=20817]: Fix inspect.getcallargs() to fail correctly if more than 3 arguments are missing. Patch by Jeremiah Lowin.
- [bpo-6676](https://bugs.python.org/issue?@action=redirect&bpo=6676) [https://bugs.python.org/issue?@action=redirect&bpo=6676]: Ensure a meaningful exception is raised when attempting to parse more than one XML document per pyexpat xmlparser instance. (Original patches by Hirokazu Yamamoto and Amaury Forgeot d'Arc, with suggested wording by David Gutteridge)
- [bpo-21117](https://bugs.python.org/issue?@action=redirect&bpo=21117) [https://bugs.python.org/issue?@action=redirect&bpo=21117]: Fix inspect.signature to better support functools.partial. Due to the specifics of functools.partial implementation, positional-or-keyword arguments passed as keyword arguments become keyword-only.
- [bpo-20334](https://bugs.python.org/issue?@action=redirect&bpo=20334) [https://bugs.python.org/issue?@action=redirect&bpo=20334]: inspect.Signature and inspect.Parameter are now hashable. Thanks to Antony Lee

for bug reports and suggestions.

- [bpo-15916](https://bugs.python.org/issue?@action=redirect&bpo=15916) [https://bugs.python.org/issue?@action=redirect&bpo=15916]: `doctest.DocTestSuite` returns an empty `unittest.TestSuite` instead of raising `ValueError` if it finds no tests
- [bpo-21209](https://bugs.python.org/issue?@action=redirect&bpo=21209) [https://bugs.python.org/issue?@action=redirect&bpo=21209]: Fix `asyncio.tasks.CoroWrapper` to workaround a bug in `yield-from` implementation in CPython's prior to 3.4.1.
- `asyncio`: Add `gi_{frame,running,code}` properties to `CoroWrapper` (upstream [bpo-163](https://bugs.python.org/issue?@action=redirect&bpo=163) [https://bugs.python.org/issue?@action=redirect&bpo=163]).
- [bpo-21311](https://bugs.python.org/issue?@action=redirect&bpo=21311) [https://bugs.python.org/issue?@action=redirect&bpo=21311]: Avoid exception in `_osx_support` with non-standard compiler configurations. Patch by John Szakmeister.
- [bpo-11571](https://bugs.python.org/issue?@action=redirect&bpo=11571) [https://bugs.python.org/issue?@action=redirect&bpo=11571]: Ensure that the turtle window becomes the topmost window when launched on OS X.
- [bpo-21801](https://bugs.python.org/issue?@action=redirect&bpo=21801) [https://bugs.python.org/issue?@action=redirect&bpo=21801]: Validate that `__signature__` is `None` or an instance of `Signature`.
- [bpo-21923](https://bugs.python.org/issue?@action=redirect&bpo=21923) [https://bugs.python.org/issue?@action=redirect&bpo=21923]: Prevent `AttributeError` in `distutils.sysconfig.customize_compiler` due to possible uninitialized `_config_vars`.
- [bpo-21323](https://bugs.python.org/issue?@action=redirect&bpo=21323) [https://bugs.python.org/issue?@action=redirect&bpo=21323]: Fix `http.server` to again handle scripts in CGI subdirectories, broken by the fix for security [bpo-19435](https://bugs.python.org/issue?@action=redirect&bpo=19435) [https://bugs.python.org/issue?@action=redirect&bpo=19435]. Patch by Zach Byrne.
- [bpo-22733](https://bugs.python.org/issue?@action=redirect&bpo=22733) [https://bugs.python.org/issue?@action=redirect&bpo=22733]: Fix `ffi_prep_args` not zero-extending argument values correctly on 64-bit Windows.
- [bpo-23302](https://bugs.python.org/issue?@action=redirect&bpo=23302) [https://bugs.python.org/issue?@action=redirect&bpo=23302]: Default to `TCP_NODELAY = 1` upon establishing an `HTTPConnection`. Removed use of hard-coded `MSS` as it's an optimization that's no longer needed with Nagle disabled.

## IDLE

- [bpo-20577](https://bugs.python.org/issue?@action=redirect&bpo=20577) [https://bugs.python.org/issue?@action=redirect&bpo=20577]: Configuration of the max line length for the FormatParagraph extension has been moved from the General tab of the Idle preferences dialog to the FormatParagraph tab of the Config Extensions dialog. Patch by Tal Einat.
- [bpo-16893](https://bugs.python.org/issue?@action=redirect&bpo=16893) [https://bugs.python.org/issue?@action=redirect&bpo=16893]: Update Idle doc chapter to match current Idle and add new information.
- [bpo-3068](https://bugs.python.org/issue?@action=redirect&bpo=3068) [https://bugs.python.org/issue?@action=redirect&bpo=3068]: Add Idle extension configuration dialog to Options menu. Changes are written to HOME/.idlerc/config-extensions.cfg. Original patch by Tal Einat.
- [bpo-16233](https://bugs.python.org/issue?@action=redirect&bpo=16233) [https://bugs.python.org/issue?@action=redirect&bpo=16233]: A module browser (File : Class Browser, Alt + C) requires an editor window with a filename. When Class Browser is requested otherwise, from a shell, output window, or 'Untitled' editor, Idle no longer displays an error box. It now pops up an Open Module box (Alt + M). If a valid name is entered and a module is opened, a corresponding browser is also opened.
- [bpo-4832](https://bugs.python.org/issue?@action=redirect&bpo=4832) [https://bugs.python.org/issue?@action=redirect&bpo=4832]: Save As to type Python files automatically adds .py to the name you enter (even if your system does not display it). Some systems automatically add .txt when type is Text files.
- [bpo-21986](https://bugs.python.org/issue?@action=redirect&bpo=21986) [https://bugs.python.org/issue?@action=redirect&bpo=21986]: Code objects are not normally pickled by the pickle module. To match this, they are no longer pickled when running under Idle.
- [bpo-17390](https://bugs.python.org/issue?@action=redirect&bpo=17390) [https://bugs.python.org/issue?@action=redirect&bpo=17390]: Adjust Editor window title; remove 'Python', move version to end.
- [bpo-14105](https://bugs.python.org/issue?@action=redirect&bpo=14105) [https://bugs.python.org/issue?@action=redirect&bpo=14105]: Idle debugger breakpoints no longer disappear when inserting or deleting lines.
- [bpo-17172](https://bugs.python.org/issue?@action=redirect&bpo=17172) [https://bugs.python.org/issue?@action=redirect&bpo=17172]: Turtledemo can now be run from Idle. Currently, the entry is on the Help menu, but it may

move to Run. Patch by Ramchandra Apt and Lita Cho.

- [bpo-21765](https://bugs.python.org/issue?@action=redirect&bpo=21765) [https://bugs.python.org/issue?@action=redirect&bpo=21765]: Add support for non-ascii identifiers to HyperParser.
- [bpo-21940](https://bugs.python.org/issue?@action=redirect&bpo=21940) [https://bugs.python.org/issue?@action=redirect&bpo=21940]: Add unittest for WidgetRedirector. Initial patch by Saimadhav Heblikar.
- [bpo-18592](https://bugs.python.org/issue?@action=redirect&bpo=18592) [https://bugs.python.org/issue?@action=redirect&bpo=18592]: Add unittest for SearchDialogBase. Patch by Phil Webster.
- [bpo-21694](https://bugs.python.org/issue?@action=redirect&bpo=21694) [https://bugs.python.org/issue?@action=redirect&bpo=21694]: Add unittest for ParenMatch. Patch by Saimadhav Heblikar.
- [bpo-21686](https://bugs.python.org/issue?@action=redirect&bpo=21686) [https://bugs.python.org/issue?@action=redirect&bpo=21686]: add unittest for HyperParser. Original patch by Saimadhav Heblikar.
- [bpo-12387](https://bugs.python.org/issue?@action=redirect&bpo=12387) [https://bugs.python.org/issue?@action=redirect&bpo=12387]: Add missing upper(lower)case versions of default Windows key bindings for Idle so Caps Lock does not disable them. Patch by Roger Serwy.
- [bpo-21695](https://bugs.python.org/issue?@action=redirect&bpo=21695) [https://bugs.python.org/issue?@action=redirect&bpo=21695]: Closing a Find-in-files output window while the search is still in progress no longer closes Idle.
- [bpo-18910](https://bugs.python.org/issue?@action=redirect&bpo=18910) [https://bugs.python.org/issue?@action=redirect&bpo=18910]: Add unittest for textView. Patch by Phil Webster.
- [bpo-18292](https://bugs.python.org/issue?@action=redirect&bpo=18292) [https://bugs.python.org/issue?@action=redirect&bpo=18292]: Add unittest for AutoExpand. Patch by Saihadhav Heblikar.
- [bpo-18409](https://bugs.python.org/issue?@action=redirect&bpo=18409) [https://bugs.python.org/issue?@action=redirect&bpo=18409]: Add unittest for AutoComplete. Patch by Phil Webster.
- [bpo-21477](https://bugs.python.org/issue?@action=redirect&bpo=21477) [https://bugs.python.org/issue?@action=redirect&bpo=21477]: htest.py - Improve framework, complete set of tests. Patches by Saimadhav Heblikar
- [bpo-18104](https://bugs.python.org/issue?@action=redirect&bpo=18104) [https://bugs.python.org/issue?@action=redirect&bpo=18104]: Add idlib/idle\_test/htest.py with a few sample tests to begin consolidating and improving human-validated tests of Idle. Change other files as needed to

work with htest. Running the module as `_main_` runs all tests.

- [bpo-21139](https://bugs.python.org/issue?@action=redirect&bpo=21139) [https://bugs.python.org/issue?@action=redirect&bpo=21139]: Change default paragraph width to 72, the [PEP 8](https://peps.python.org/pep-0008/) [https://peps.python.org/pep-0008/] recommendation.
- [bpo-21284](https://bugs.python.org/issue?@action=redirect&bpo=21284) [https://bugs.python.org/issue?@action=redirect&bpo=21284]: Paragraph reformat test passes after user changes reformat width.
- [bpo-17654](https://bugs.python.org/issue?@action=redirect&bpo=17654) [https://bugs.python.org/issue?@action=redirect&bpo=17654]: Ensure IDLE menus are customized properly on OS X for non-framework builds and for all variants of Tk.
- [bpo-23180](https://bugs.python.org/issue?@action=redirect&bpo=23180) [https://bugs.python.org/issue?@action=redirect&bpo=23180]: Rename IDLE “Windows” menu item to “Window”. Patch by Al Sweigart.

## Build

- [bpo-15506](https://bugs.python.org/issue?@action=redirect&bpo=15506) [https://bugs.python.org/issue?@action=redirect&bpo=15506]: Use standard `PKG_PROG_PKG_CONFIG` autoconf macro in the configure script.
- [bpo-22935](https://bugs.python.org/issue?@action=redirect&bpo=22935) [https://bugs.python.org/issue?@action=redirect&bpo=22935]: Allow the ssl module to be compiled if openssl doesn’t support SSL 3.
- [bpo-22592](https://bugs.python.org/issue?@action=redirect&bpo=22592) [https://bugs.python.org/issue?@action=redirect&bpo=22592]: Drop support of the Borland C compiler to build Python. The distutils module still supports it to build extensions.
- [bpo-22591](https://bugs.python.org/issue?@action=redirect&bpo=22591) [https://bugs.python.org/issue?@action=redirect&bpo=22591]: Drop support of MS-DOS, especially of the DJGPP compiler (MS-DOS port of GCC).
- [bpo-16537](https://bugs.python.org/issue?@action=redirect&bpo=16537) [https://bugs.python.org/issue?@action=redirect&bpo=16537]: Check whether `self.extensions` is empty in `setup.py`. Patch by Jonathan Hosmer.
- [bpo-22359](https://bugs.python.org/issue?@action=redirect&bpo=22359) [https://bugs.python.org/issue?@action=redirect&bpo=22359]: Remove incorrect uses of recursive make. Patch by Jonas Wagner.
- [bpo-21958](https://bugs.python.org/issue?@action=redirect&bpo=21958) [https://bugs.python.org/issue?@action=redirect&bpo=21958]

@action=redirect&bpo=21958]: Define HAVE\_ROUND when building with Visual Studio 2013 and above. Patch by Zachary Turner.

- [bpo-18093](https://bugs.python.org/issue?@action=redirect&bpo=18093) [https://bugs.python.org/issue?@action=redirect&bpo=18093]: the programs that embed the CPython runtime are now in a separate “Programs” directory, rather than being kept in the Modules directory.
- [bpo-15759](https://bugs.python.org/issue?@action=redirect&bpo=15759) [https://bugs.python.org/issue?@action=redirect&bpo=15759]: “make suspicious”, “make linkcheck” and “make doctest” in Doc/ now display special message when and only when there are failures.
- [bpo-21141](https://bugs.python.org/issue?@action=redirect&bpo=21141) [https://bugs.python.org/issue?@action=redirect&bpo=21141]: The Windows build process no longer attempts to find Perl, instead relying on OpenSSL source being configured and ready to build. The PCbuild\build\_ssl.py script has been re-written and re-named to PCbuild\prepare\_ssl.py, and takes care of configuring OpenSSL source for both 32 and 64 bit platforms. OpenSSL sources obtained from svn.python.org will always be pre-configured and ready to build.
- [bpo-21037](https://bugs.python.org/issue?@action=redirect&bpo=21037) [https://bugs.python.org/issue?@action=redirect&bpo=21037]: Add a build option to enable AddressSanitizer support.
- [bpo-19962](https://bugs.python.org/issue?@action=redirect&bpo=19962) [https://bugs.python.org/issue?@action=redirect&bpo=19962]: The Windows build process now creates “python.bat” in the root of the source tree, which passes all arguments through to the most recently built interpreter.
- [bpo-21285](https://bugs.python.org/issue?@action=redirect&bpo=21285) [https://bugs.python.org/issue?@action=redirect&bpo=21285]: Refactor and fix curses configure check to always search in a ncursesw directory.
- [bpo-15234](https://bugs.python.org/issue?@action=redirect&bpo=15234) [https://bugs.python.org/issue?@action=redirect&bpo=15234]: For BerkeleyDB and Sqlite, only add the found library and include directories if they aren’t already being searched. This avoids an explicit runtime library dependency.
- [bpo-17861](https://bugs.python.org/issue?@action=redirect&bpo=17861) [https://bugs.python.org/issue?@action=redirect&bpo=17861]: Tools/scripts/generate\_opcode.h.py automatically regenerates Include/opcode.h from Lib/opcode.py if the latter gets any change.

- [bpo-20644](https://bugs.python.org/issue?@action=redirect&bpo=20644) [https://bugs.python.org/issue?@action=redirect&bpo=20644]: OS X installer build support for documentation build changes in 3.4.1: assume externally supplied sphinx-build is available in /usr/bin.
- [bpo-20022](https://bugs.python.org/issue?@action=redirect&bpo=20022) [https://bugs.python.org/issue?@action=redirect&bpo=20022]: Eliminate use of deprecated bundlebuilder in OS X builds.
- [bpo-15968](https://bugs.python.org/issue?@action=redirect&bpo=15968) [https://bugs.python.org/issue?@action=redirect&bpo=15968]: Incorporated Tcl, Tk, and Tix builds into the Windows build solution.
- [bpo-17095](https://bugs.python.org/issue?@action=redirect&bpo=17095) [https://bugs.python.org/issue?@action=redirect&bpo=17095]: Fix Modules/Setup *shared* support.
- [bpo-21811](https://bugs.python.org/issue?@action=redirect&bpo=21811) [https://bugs.python.org/issue?@action=redirect&bpo=21811]: Anticipated fixes to support OS X versions > 10.9.
- [bpo-21166](https://bugs.python.org/issue?@action=redirect&bpo=21166) [https://bugs.python.org/issue?@action=redirect&bpo=21166]: Prevent possible segfaults and other random failures of python -generate-posix-vars in pybuilddir.txt build target.
- [bpo-18096](https://bugs.python.org/issue?@action=redirect&bpo=18096) [https://bugs.python.org/issue?@action=redirect&bpo=18096]: Fix library order returned by python-config.
- [bpo-17219](https://bugs.python.org/issue?@action=redirect&bpo=17219) [https://bugs.python.org/issue?@action=redirect&bpo=17219]: Add library build dir for Python extension cross-builds.
- [bpo-22919](https://bugs.python.org/issue?@action=redirect&bpo=22919) [https://bugs.python.org/issue?@action=redirect&bpo=22919]: Windows build updated to support VC 14.0 (Visual Studio 2015), which will be used for the official release.
- [bpo-21236](https://bugs.python.org/issue?@action=redirect&bpo=21236) [https://bugs.python.org/issue?@action=redirect&bpo=21236]: Build \_msi.pyd with cabinet.lib instead of fci.lib
- [bpo-17128](https://bugs.python.org/issue?@action=redirect&bpo=17128) [https://bugs.python.org/issue?@action=redirect&bpo=17128]: Use private version of OpenSSL for OS X 10.5+ installer.

## C API

- [bpo-14203](https://bugs.python.org/issue?@action=redirect&bpo=14203) [https://bugs.python.org/issue?@action=redirect&bpo=14203]

@action=redirect&bpo=14203]: Remove obsolete support for view == NULL in PyBuffer\_FillInfo(), bytearray\_getbuffer(), bytesiobuf\_getbuffer() and array\_buffer\_getbuf(). All functions now raise BufferError in that case.

- [bpo-22445](https://bugs.python.org/issue?@action=redirect&bpo=22445) [https://bugs.python.org/issue?@action=redirect&bpo=22445]: PyBuffer\_IsContiguous() now implements precise contiguity tests, compatible with NumPy's NPY\_RELAXED\_STRIDES\_CHECKING compilation flag. Previously the function reported false negatives for corner cases.
- [bpo-22079](https://bugs.python.org/issue?@action=redirect&bpo=22079) [https://bugs.python.org/issue?@action=redirect&bpo=22079]: PyType\_Ready() now checks that statically allocated type has no dynamically allocated bases.
- [bpo-22453](https://bugs.python.org/issue?@action=redirect&bpo=22453) [https://bugs.python.org/issue?@action=redirect&bpo=22453]: Removed non-documented macro PyObject\_REPR().
- [bpo-18395](https://bugs.python.org/issue?@action=redirect&bpo=18395) [https://bugs.python.org/issue?@action=redirect&bpo=18395]: Rename `_Py_char2wchar()` to **`Py_DecodeLocale()`**, rename `_Py_wchar2char()` to **`Py_EncodeLocale()`**, and document these functions.
- [bpo-21233](https://bugs.python.org/issue?@action=redirect&bpo=21233) [https://bugs.python.org/issue?@action=redirect&bpo=21233]: Add new C functions: PyMem\_RawCalloc(), PyMem\_Calloc(), PyObject\_Calloc(), PyObject\_GC\_Calloc(). bytes(int) is now using `calloc()` instead of `malloc()` for large objects which is faster and use less memory.
- [bpo-20942](https://bugs.python.org/issue?@action=redirect&bpo=20942) [https://bugs.python.org/issue?@action=redirect&bpo=20942]: PyImport\_ImportFrozenModuleObject() no longer sets `_file_` to match what importlib does; this affects `_frozen_importlib` as well as any module loaded using `imp.init_frozen()`.

## Documentation

- [bpo-19548](https://bugs.python.org/issue?@action=redirect&bpo=19548) [https://bugs.python.org/issue?@action=redirect&bpo=19548]: Update the codecs module documentation to better cover the distinction between text encodings and other codecs, together with other clarifications. Patch by Martin Panter.
- [bpo-22394](https://bugs.python.org/issue?@action=redirect&bpo=22394) [https://bugs.python.org/issue?@action=redirect&bpo=22394]

@action=redirect&bpo=22394]: Doc/Makefile now supports `make venv PYTHON=../python` to create a venv for generating the documentation, e.g., `make html PYTHON=venv/bin/python3`.

- [bpo-21514](https://bugs.python.org/issue?@action=redirect&bpo=21514) [https://bugs.python.org/issue?@action=redirect&bpo=21514]: The documentation of the json module now refers to new JSON RFC 7159 instead of obsoleted RFC 4627.
- [bpo-21777](https://bugs.python.org/issue?@action=redirect&bpo=21777) [https://bugs.python.org/issue?@action=redirect&bpo=21777]: The binary sequence methods on bytes and bytearray are now documented explicitly, rather than assuming users will be able to derive the expected behaviour from the behaviour of the corresponding str methods.
- [bpo-6916](https://bugs.python.org/issue?@action=redirect&bpo=6916) [https://bugs.python.org/issue?@action=redirect&bpo=6916]: undocument deprecated `asynchat.fifo` class.
- [bpo-17386](https://bugs.python.org/issue?@action=redirect&bpo=17386) [https://bugs.python.org/issue?@action=redirect&bpo=17386]: Expanded functionality of the `Doc/make.bat` script to make it much more comparable to `Doc/Makefile`.
- [bpo-21312](https://bugs.python.org/issue?@action=redirect&bpo=21312) [https://bugs.python.org/issue?@action=redirect&bpo=21312]: Update the `thread_foobar.h` template file to include newer threading APIs. Patch by Jack McCracken.
- [bpo-21043](https://bugs.python.org/issue?@action=redirect&bpo=21043) [https://bugs.python.org/issue?@action=redirect&bpo=21043]: Remove the recommendation for specific CA organizations and to mention the ability to load the OS certificates.
- [bpo-20765](https://bugs.python.org/issue?@action=redirect&bpo=20765) [https://bugs.python.org/issue?@action=redirect&bpo=20765]: Add missing documentation for `PurePath.with_name()` and `PurePath.with_suffix()`.
- [bpo-19407](https://bugs.python.org/issue?@action=redirect&bpo=19407) [https://bugs.python.org/issue?@action=redirect&bpo=19407]: New package installation and distribution guides based on the Python Packaging Authority tools. Existing guides have been retained as legacy links from the `distutils` docs, as they still contain some required reference material for tool developers that isn't recorded anywhere else.
- [bpo-19697](https://bugs.python.org/issue?@action=redirect&bpo=19697) [https://bugs.python.org/issue?@action=redirect&bpo=19697]: Document cases where

`__main__.__spec__` is None.

## Tests

- [bpo-18982](https://bugs.python.org/issue?@action=redirect&bpo=18982) [https://bugs.python.org/issue?@action=redirect&bpo=18982]: Add tests for CLI of the calendar module.
- [bpo-19548](https://bugs.python.org/issue?@action=redirect&bpo=19548) [https://bugs.python.org/issue?@action=redirect&bpo=19548]: Added some additional checks to `test_codecs` to ensure that statements in the updated documentation remain accurate. Patch by Martin Panter.
- [bpo-22838](https://bugs.python.org/issue?@action=redirect&bpo=22838) [https://bugs.python.org/issue?@action=redirect&bpo=22838]: All `test_re` tests now work with unittest test discovery.
- [bpo-22173](https://bugs.python.org/issue?@action=redirect&bpo=22173) [https://bugs.python.org/issue?@action=redirect&bpo=22173]: Update `lib2to3` tests to use unittest test discovery.
- [bpo-16000](https://bugs.python.org/issue?@action=redirect&bpo=16000) [https://bugs.python.org/issue?@action=redirect&bpo=16000]: Convert `test_curses` to use unittest.
- [bpo-21456](https://bugs.python.org/issue?@action=redirect&bpo=21456) [https://bugs.python.org/issue?@action=redirect&bpo=21456]: Skip two tests in `test_urllib2net.py` if `_ssl` module not present. Patch by Remi Pointel.
- [bpo-20746](https://bugs.python.org/issue?@action=redirect&bpo=20746) [https://bugs.python.org/issue?@action=redirect&bpo=20746]: Fix `test_pdb` to run in `refleak` mode (-R). Patch by Xavier de Gaye.
- [bpo-22060](https://bugs.python.org/issue?@action=redirect&bpo=22060) [https://bugs.python.org/issue?@action=redirect&bpo=22060]: `test_ctypes` has been somewhat cleaned up and simplified; it now uses unittest test discovery to find its tests.
- [bpo-22104](https://bugs.python.org/issue?@action=redirect&bpo=22104) [https://bugs.python.org/issue?@action=redirect&bpo=22104]: `regtest.py` no longer holds a reference to the suite of tests loaded from test modules that don't define `test_main()`.
- [bpo-22111](https://bugs.python.org/issue?@action=redirect&bpo=22111) [https://bugs.python.org/issue?@action=redirect&bpo=22111]: Assorted cleanups in `test_imaplib`. Patch by Milan Oberkirch.
- [bpo-22002](https://bugs.python.org/issue?@action=redirect&bpo=22002) [https://bugs.python.org/issue?@action=redirect&bpo=22002]: Added `load_package_tests` function to `test.support` and used it to implement/augment test discovery in `test_asyncio`, `test_email`, `test_importlib`,

test\_json, and test\_tools.

- [bpo-21976](https://bugs.python.org/issue?@action=redirect&bpo=21976) [https://bugs.python.org/issue?@action=redirect&bpo=21976]: Fix test\_ssl to accept LibreSSL version strings. Thanks to William Orr.
- [bpo-21918](https://bugs.python.org/issue?@action=redirect&bpo=21918) [https://bugs.python.org/issue?@action=redirect&bpo=21918]: Converted test\_tools from a module to a package containing separate test files for each tested script.
- [bpo-9554](https://bugs.python.org/issue?@action=redirect&bpo=9554) [https://bugs.python.org/issue?@action=redirect&bpo=9554]: Use modern unittest features in test\_argparse. Initial patch by Denver Coneybeare and Radu Voicilas.
- [bpo-20155](https://bugs.python.org/issue?@action=redirect&bpo=20155) [https://bugs.python.org/issue?@action=redirect&bpo=20155]: Changed HTTP method names in failing tests in test\_httpservers so that packet filtering software (specifically Windows Base Filtering Engine) does not interfere with the transaction semantics expected by the tests.
- [bpo-19493](https://bugs.python.org/issue?@action=redirect&bpo=19493) [https://bugs.python.org/issue?@action=redirect&bpo=19493]: Refactored the ctypes test package to skip tests explicitly rather than silently.
- [bpo-18492](https://bugs.python.org/issue?@action=redirect&bpo=18492) [https://bugs.python.org/issue?@action=redirect&bpo=18492]: All resources are now allowed when tests are not run by regrtest.py.
- [bpo-21634](https://bugs.python.org/issue?@action=redirect&bpo=21634) [https://bugs.python.org/issue?@action=redirect&bpo=21634]: Fix pystone micro-benchmark: use floor division instead of true division to benchmark integers instead of floating point numbers. Set pystone version to 1.2. Patch written by Lennart Regebro.
- [bpo-21605](https://bugs.python.org/issue?@action=redirect&bpo=21605) [https://bugs.python.org/issue?@action=redirect&bpo=21605]: Added tests for Tkinter images.
- [bpo-21493](https://bugs.python.org/issue?@action=redirect&bpo=21493) [https://bugs.python.org/issue?@action=redirect&bpo=21493]: Added test for ntpath.expanduser(). Original patch by Claudiu Popa.
- [bpo-19925](https://bugs.python.org/issue?@action=redirect&bpo=19925) [https://bugs.python.org/issue?@action=redirect&bpo=19925]: Added tests for the spwd module. Original patch by Vajrasky Kok.
- [bpo-21522](https://bugs.python.org/issue?@action=redirect&bpo=21522) [https://bugs.python.org/issue?@action=redirect&bpo=21522]: Added Tkinter tests for Listbox.itemconfigure(), PanedWindow.paneconfigure(), and Menu.entryconfigure().

- [bpo-17756](https://bugs.python.org/issue?@action=redirect&bpo=17756) [https://bugs.python.org/issue?@action=redirect&bpo=17756]: Fix test\_code test when run from the installed location.
- [bpo-17752](https://bugs.python.org/issue?@action=redirect&bpo=17752) [https://bugs.python.org/issue?@action=redirect&bpo=17752]: Fix distutils tests when run from the installed location.
- [bpo-18604](https://bugs.python.org/issue?@action=redirect&bpo=18604) [https://bugs.python.org/issue?@action=redirect&bpo=18604]: Consolidated checks for GUI availability. All platforms now at least check whether Tk can be instantiated when the GUI resource is requested.
- [bpo-21275](https://bugs.python.org/issue?@action=redirect&bpo=21275) [https://bugs.python.org/issue?@action=redirect&bpo=21275]: Fix a socket test on KFreeBSD.
- [bpo-21223](https://bugs.python.org/issue?@action=redirect&bpo=21223) [https://bugs.python.org/issue?@action=redirect&bpo=21223]: Pass test\_site/test\_startup\_imports when some of the extensions are built as builtins.
- [bpo-20635](https://bugs.python.org/issue?@action=redirect&bpo=20635) [https://bugs.python.org/issue?@action=redirect&bpo=20635]: Added tests for Tk geometry managers.
- Add test case for freeze.
- [bpo-20743](https://bugs.python.org/issue?@action=redirect&bpo=20743) [https://bugs.python.org/issue?@action=redirect&bpo=20743]: Fix a reference leak in test\_tcl.
- [bpo-21097](https://bugs.python.org/issue?@action=redirect&bpo=21097) [https://bugs.python.org/issue?@action=redirect&bpo=21097]: Move test\_namespace\_pkgs into test\_importlib.
- [bpo-21503](https://bugs.python.org/issue?@action=redirect&bpo=21503) [https://bugs.python.org/issue?@action=redirect&bpo=21503]: Use test\_both() consistently in test\_importlib.

## Tools/Demos

- [bpo-22314](https://bugs.python.org/issue?@action=redirect&bpo=22314) [https://bugs.python.org/issue?@action=redirect&bpo=22314]: pydoc now works when the LINES environment variable is set.
- [bpo-22615](https://bugs.python.org/issue?@action=redirect&bpo=22615) [https://bugs.python.org/issue?@action=redirect&bpo=22615]: Argument Clinic now supports the “type” argument for the int converter. This permits using the int converter with enums and typedefs.
- [bpo-20076](https://bugs.python.org/issue?@action=redirect&bpo=20076) [https://bugs.python.org/issue?@action=redirect&bpo=20076]: The makelocalealias.py script no longer ignores UTF-8 mapping.
- [bpo-20079](https://bugs.python.org/issue?@action=redirect&bpo=20079) [https://bugs.python.org/issue?@action=redirect&bpo=20079]: The makelocalealias.py script now can parse the SUPPORTED file from glibc sources and supports command line options for source paths.
- [bpo-22201](https://bugs.python.org/issue?@action=redirect&bpo=22201) [https://bugs.python.org/issue?@action=redirect&bpo=22201]: Command-line interface of the zipfile module now correctly extracts ZIP files with directory entries. Patch by Ryan Wilson.
- [bpo-22120](https://bugs.python.org/issue?@action=redirect&bpo=22120) [https://bugs.python.org/issue?@action=redirect&bpo=22120]: For functions using an unsigned integer return converter, Argument Clinic now generates a cast to that type for the comparison to -1 in the generated code. (This suppresses a compilation warning.)
- [bpo-18974](https://bugs.python.org/issue?@action=redirect&bpo=18974) [https://bugs.python.org/issue?@action=redirect&bpo=18974]: Tools/scripts/diff.py now uses argparse instead of optparse.
- [bpo-21906](https://bugs.python.org/issue?@action=redirect&bpo=21906) [https://bugs.python.org/issue?@action=redirect&bpo=21906]: Make Tools/scripts/md5sum.py work in Python 3. Patch by Zachary Ware.

- [bpo-21629](https://bugs.python.org/issue?@action=redirect&bpo=21629) [https://bugs.python.org/issue?@action=redirect&bpo=21629]: Fix Argument Clinic’s “–converters” feature.
- Add support for `yield from` to 2to3.
- Add support for the [PEP 465](https://peps.python.org/pep-0465/) [https://peps.python.org/pep-0465/] matrix multiplication operator to 2to3.
- [bpo-16047](https://bugs.python.org/issue?@action=redirect&bpo=16047) [https://bugs.python.org/issue?@action=redirect&bpo=16047]: Fix module exception list and `_file_` handling in freeze. Patch by Meador Inge.
- [bpo-11824](https://bugs.python.org/issue?@action=redirect&bpo=11824) [https://bugs.python.org/issue?@action=redirect&bpo=11824]: Consider ABI tags in freeze. Patch by Meador Inge.
- [bpo-20535](https://bugs.python.org/issue?@action=redirect&bpo=20535) [https://bugs.python.org/issue?@action=redirect&bpo=20535]: PYTHONWARNING no longer affects the `run_tests.py` script. Patch by Arfrever Frehtes Taifersar Arahesis.

## Windows

- [bpo-23260](https://bugs.python.org/issue?@action=redirect&bpo=23260) [https://bugs.python.org/issue?@action=redirect&bpo=23260]: Update Windows installer
- The bundled version of Tcl/Tk has been updated to 8.6.3. The most visible result of this change is the addition of new native file dialogs when running on Windows Vista or newer. See Tcl/Tk’s TIP 432 for more information. Also, this version of Tcl/Tk includes support for Windows 10.
- [bpo-17896](https://bugs.python.org/issue?@action=redirect&bpo=17896) [https://bugs.python.org/issue?@action=redirect&bpo=17896]: The Windows build scripts now expect external library sources to be in `PCbuild\...\externals` rather than `PCbuild\...\...`
- [bpo-17717](https://bugs.python.org/issue?@action=redirect&bpo=17717) [https://bugs.python.org/issue?@action=redirect&bpo=17717]: The Windows build scripts now use a copy of NASM pulled from `svn.python.org` to build OpenSSL.
- [bpo-21907](https://bugs.python.org/issue?@action=redirect&bpo=21907) [https://bugs.python.org/issue?@action=redirect&bpo=21907]: Improved the batch scripts provided for building Python.
- [bpo-22644](https://bugs.python.org/issue?@action=redirect&bpo=22644) [https://bugs.python.org/issue?@action=redirect&bpo=22644]: The bundled version of OpenSSL has been updated to 1.0.1j.

- [bpo-10747](https://bugs.python.org/issue?@action=redirect&bpo=10747) [https://bugs.python.org/issue?@action=redirect&bpo=10747]: Use versioned labels in the Windows start menu. Patch by Olive Kilburn.
- [bpo-22980](https://bugs.python.org/issue?@action=redirect&bpo=22980) [https://bugs.python.org/issue?@action=redirect&bpo=22980]: .pyd files with a version and platform tag (for example, “.cp35-win32.pyd”) will now be loaded in preference to those without tags.

**(For information about older versions, consult the HISTORY file.)**

# The Python Tutorial

Python is an easy to learn, powerful programming language. It has efficient high-level data structures and a simple but effective approach to object-oriented programming. Python's elegant syntax and dynamic typing, together with its interpreted nature, make it an ideal language for scripting and rapid application development in many areas on most platforms.

The Python interpreter and the extensive standard library are freely available in source or binary form for all major platforms from the Python web site, <https://www.python.org/>, and may be freely distributed. The same site also contains distributions of and pointers to many free third party Python modules, programs and tools, and additional documentation.

The Python interpreter is easily extended with new functions and data types implemented in C or C++ (or other languages callable from C). Python is also suitable as an extension language for customizable applications.

This tutorial introduces the reader informally to the basic concepts and features of the Python language and system. It helps to have a Python interpreter handy for hands-on experience, but all examples are self-contained, so the tutorial can be read off-line as well.

For a description of standard objects and modules, see [The Python Standard Library](#). [The Python Language Reference](#) gives a more formal definition of the language. To write extensions in C or C++, read [Extending and Embedding the Python Interpreter](#) and [Python/C API Reference Manual](#). There are also several books covering Python in depth.

This tutorial does not attempt to be comprehensive and cover every single feature, or even every commonly used feature. Instead, it introduces many of Python's most noteworthy features, and will give you a good idea of the language's flavor and style. After

reading it, you will be able to read and write Python modules and programs, and you will be ready to learn more about the various Python library modules described in [The Python Standard Library](#).

The [Glossary](#) is also worth going through.

# 1. Whetting Your Appetite

If you do much work on computers, eventually you find that there's some task you'd like to automate. For example, you may wish to perform a search-and-replace over a large number of text files, or rename and rearrange a bunch of photo files in a complicated way. Perhaps you'd like to write a small custom database, or a specialized GUI application, or a simple game.

If you're a professional software developer, you may have to work with several C/C++/Java libraries but find the usual write/compile/test/re-compile cycle is too slow. Perhaps you're writing a test suite for such a library and find writing the testing code a tedious task. Or maybe you've written a program that could use an extension language, and you don't want to design and implement a whole new language for your application.

Python is just the language for you.

You could write a Unix shell script or Windows batch files for some of these tasks, but shell scripts are best at moving around files and changing text data, not well-suited for GUI applications or games. You could write a C/C++/Java program, but it can take a lot of development time to get even a first-draft program. Python is simpler to use, available on Windows, macOS, and Unix operating systems, and will help you get the job done more quickly.

Python is simple to use, but it is a real programming language, offering much more structure and support for large programs than shell scripts or batch files can offer. On the other hand, Python also offers much more error checking than C, and, being a *very-high-level language*, it has high-level data types built in, such as flexible arrays and dictionaries. Because of its more general data types Python is applicable to a much larger problem domain than Awk or even Perl, yet many things are at least as easy in Python as in those languages.

Python allows you to split your program into modules that can be

reused in other Python programs. It comes with a large collection of standard modules that you can use as the basis of your programs — or as examples to start learning to program in Python. Some of these modules provide things like file I/O, system calls, sockets, and even interfaces to graphical user interface toolkits like Tk.

Python is an interpreted language, which can save you considerable time during program development because no compilation and linking is necessary. The interpreter can be used interactively, which makes it easy to experiment with features of the language, to write throw-away programs, or to test functions during bottom-up program development. It is also a handy desk calculator.

Python enables programs to be written compactly and readably. Programs written in Python are typically much shorter than equivalent C, C++, or Java programs, for several reasons:

- the high-level data types allow you to express complex operations in a single statement;
- statement grouping is done by indentation instead of beginning and ending brackets;
- no variable or argument declarations are necessary.

Python is *extensible*: if you know how to program in C it is easy to add a new built-in function or module to the interpreter, either to perform critical operations at maximum speed, or to link Python programs to libraries that may only be available in binary form (such as a vendor-specific graphics library). Once you are really hooked, you can link the Python interpreter into an application written in C and use it as an extension or command language for that application.

By the way, the language is named after the BBC show “Monty Python’s Flying Circus” and has nothing to do with reptiles. Making references to Monty Python skits in documentation is not only allowed, it is encouraged!

Now that you are all excited about Python, you’ll want to examine it in some more detail. Since the best way to learn a language is to use it, the tutorial invites you to play with the Python interpreter as you read.

In the next chapter, the mechanics of using the interpreter are explained. This is rather mundane information, but essential for trying out the examples shown later.

The rest of the tutorial introduces various features of the Python language and system through examples, beginning with simple expressions, statements and data types, through functions and modules, and finally touching upon advanced concepts like exceptions and user-defined classes.

## 2. Using the Python Interpreter

### 2.1. Invoking the Interpreter

The Python interpreter is usually installed as `/usr/local/bin/python3.11` on those machines where it is available; putting `/usr/local/bin` in your Unix shell's search path makes it possible to start it by typing the command:

```
python3.11
```

to the shell. <sup>1</sup> Since the choice of the directory where the interpreter lives is an installation option, other places are possible; check with your local Python guru or system administrator. (E.g., `/usr/local/python` is a popular alternative location.)

On Windows machines where you have installed Python from the [Microsoft Store](#), the `python3.11` command will be available. If you have the [py.exe launcher](#) installed, you can use the `py` command. See [Excursus: Setting environment variables](#) for other ways to launch Python.

Typing an end-of-file character (`Control-D` on Unix, `Control-Z` on Windows) at the primary prompt causes the interpreter to exit with a zero exit status. If that doesn't work, you can exit the interpreter by typing the following command: `quit()`.

The interpreter's line-editing features include interactive editing, history substitution and code completion on systems that support the [GNU Readline](https://tiswww.case.edu/php/chet/readline/rltop.html) library. Perhaps the quickest check to see whether command line editing is supported is typing `Control-P` to the first Python prompt you get. If it beeps, you have command line editing; see Appendix [Interactive Input Editing and History Substitution](#) for an introduction to the keys. If nothing appears to happen, or if `^P` is echoed, command line editing isn't available; you'll only be able to

use backspace to remove characters from the current line.

The interpreter operates somewhat like the Unix shell: when called with standard input connected to a tty device, it reads and executes commands interactively; when called with a file name argument or with a file as standard input, it reads and executes a *script* from that file.

A second way of starting the interpreter is `python -c command [arg] ...`, which executes the statement(s) in *command*, analogous to the shell's `-c` option. Since Python statements often contain spaces or other characters that are special to the shell, it is usually advised to quote *command* in its entirety.

Some Python modules are also useful as scripts. These can be invoked using `python -m module [arg] ...`, which executes the source file for *module* as if you had spelled out its full name on the command line.

When a script file is used, it is sometimes useful to be able to run the script and enter interactive mode afterwards. This can be done by passing `-i` before the script.

All command line options are described in [Command line and environment](#).

### 2.1.1. Argument Passing

When known to the interpreter, the script name and additional arguments thereafter are turned into a list of strings and assigned to the `argv` variable in the `sys` module. You can access this list by executing `import sys`. The length of the list is at least one; when no script and no arguments are given, `sys.argv[0]` is an empty string. When the script name is given as `'-'` (meaning standard input), `sys.argv[0]` is set to `'-'`. When `-c command` is used, `sys.argv[0]` is set to `'-c'`. When `-m module` is used, `sys.argv[0]` is set to the full name of the located module.

Options found after `-c command` or `-m module` are not consumed by the Python interpreter's option processing but left in `sys.argv` for the command or module to handle.

## 2.1.2. Interactive Mode

When commands are read from a tty, the interpreter is said to be in *interactive mode*. In this mode it prompts for the next command with the *primary prompt*, usually three greater-than signs (`>>>`); for continuation lines it prompts with the *secondary prompt*, by default three dots (`. . .`). The interpreter prints a welcome message stating its version number and a copyright notice before printing the first prompt:

```
$ python3.11
Python 3.11 (default, April 4 2021, 09:25:04)
[GCC 10.2.0] on linux
Type "help", "copyright", "credits" or "license" for more
>>>
```

Continuation lines are needed when entering a multi-line construct. As an example, take a look at this [if](#) statement:

```
>>> the_world_is_flat = True
>>> if the_world_is_flat:
...     print("Be careful not to fall off!")
...
Be careful not to fall off!
```

For more on interactive mode, see [Interactive Mode](#).

## 2.2. The Interpreter and Its Environment

### 2.2.1. Source Code Encoding

By default, Python source files are treated as encoded in UTF-8. In that encoding, characters of most languages in the world can be used simultaneously in string literals, identifiers and comments — although the standard library only uses ASCII characters for identifiers, a convention that any portable code should follow. To display all these characters properly, your editor must recognize that the file is UTF-8, and it must use a font that supports all the characters in the file.

To declare an encoding other than the default one, a special comment line should be added as the *first* line of the file. The syntax is as follows:

```
# -*- coding: encoding -*-
```

where *encoding* is one of the valid [codecs](#) supported by Python.

For example, to declare that Windows-1252 encoding is to be used, the first line of your source code file should be:

```
# -*- coding: cp1252 -*-
```

One exception to the *first line* rule is when the source code starts with a [UNIX “shebang” line](#). In this case, the encoding declaration should be added as the second line of the file. For example:

```
#!/usr/bin/env python3
# -*- coding: cp1252 -*-
```

## Footnotes

### 1

On Unix, the Python 3.x interpreter is by default not installed with the executable named `python`, so that it does not conflict with a simultaneously installed Python 2.x executable.

# 3. An Informal Introduction to Python

In the following examples, input and output are distinguished by the presence or absence of prompts (`>>>` and `...`): to repeat the example, you must type everything after the prompt, when the prompt appears; lines that do not begin with a prompt are output from the interpreter. Note that a secondary prompt on a line by itself in an example means you must type a blank line; this is used to end a multi-line command.

You can toggle the display of prompts and output by clicking on `>>>` in the upper-right corner of an example box. If you hide the prompts and output for an example, then you can easily copy and paste the input lines into your interpreter.

Many of the examples in this manual, even those entered at the interactive prompt, include comments. Comments in Python start with the hash character, `#`, and extend to the end of the physical line. A comment may appear at the start of a line or following whitespace or code, but not within a string literal. A hash character within a string literal is just a hash character. Since comments are to clarify code and are not interpreted by Python, they may be omitted when typing in examples.

Some examples:

```
# this is the first comment
spam = 1    # and this is the second comment
            # ... and now a third!
text = "# This is not a comment because it's inside quot
```

## 3.1. Using Python as a Calculator

Let's try some simple Python commands. Start the interpreter and

wait for the primary prompt, `>>>`. (It shouldn't take long.)

### 3.1.1. Numbers

The interpreter acts as a simple calculator: you can type an expression at it and it will write the value. Expression syntax is straightforward: the operators `+`, `-`, `*` and `/` work just like in most other languages (for example, Pascal or C); parentheses `( )` can be used for grouping. For example:

```
>>> 2 + 2
4
>>> 50 - 5*6
20
>>> (50 - 5*6) / 4
5.0
>>> 8 / 5 # division always returns a floating point number
1.6
```

The integer numbers (e.g. 2, 4, 20) have type `int`, the ones with a fractional part (e.g. 5.0, 1.6) have type `float`. We will see more about numeric types later in the tutorial.

Division (`/`) always returns a float. To do `floor division` and get an integer result you can use the `//` operator; to calculate the remainder you can use `%`:

```
>>> 17 / 3 # classic division returns a float
5.666666666666667
>>>
>>> 17 // 3 # floor division discards the fractional part
5
>>> 17 % 3 # the % operator returns the remainder of the division
2
>>> 5 * 3 + 2 # floored quotient * divisor + remainder
17
```

With Python, it is possible to use the `**` operator to calculate powers [1](#):

```
>>> 5 ** 2 # 5 squared
25
>>> 2 ** 7 # 2 to the power of 7
128
```

The equal sign (=) is used to assign a value to a variable. Afterwards, no result is displayed before the next interactive prompt:

```
>>> width = 20
>>> height = 5 * 9
>>> width * height
900
```

If a variable is not “defined” (assigned a value), trying to use it will give you an error:

```
>>> n # try to access an undefined variable
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'n' is not defined
```

There is full support for floating point; operators with mixed type operands convert the integer operand to floating point:

```
>>> 4 * 3.75 - 1
14.0
```

In interactive mode, the last printed expression is assigned to the variable `_`. This means that when you are using Python as a desk calculator, it is somewhat easier to continue calculations, for example:

```
>>> tax = 12.5 / 100
>>> price = 100.50
>>> price * tax
12.5625
>>> price + _
113.0625
>>> round(_, 2)
```

This variable should be treated as read-only by the user. Don't explicitly assign a value to it — you would create an independent local variable with the same name masking the built-in variable with its magic behavior.

In addition to `int` and `float`, Python supports other types of numbers, such as `Decimal` and `Fraction`. Python also has built-in support for `complex numbers`, and uses the `j` or `J` suffix to indicate the imaginary part (e.g. `3+5j`).

### 3.1.2. Strings

Besides numbers, Python can also manipulate strings, which can be expressed in several ways. They can be enclosed in single quotes (`'...'`) or double quotes (`"..."`) with the same result [2](#). `\` can be used to escape quotes:

```
>>> 'spam eggs' # single quotes
'spam eggs'
>>> 'doesn\'t' # use \' to escape the single quote...
'doesn't'
>>> "doesn't" # ...or use double quotes instead
'doesn't'
>>> '"Yes," they said.'
'"Yes," they said.'
>>> "\"Yes,\" they said."
'"Yes," they said.'
>>> '"Isn\'t," they said.'
'"Isn\'t," they said.'
```

In the interactive interpreter, the output string is enclosed in quotes and special characters are escaped with backslashes. While this might sometimes look different from the input (the enclosing quotes could change), the two strings are equivalent. The string is enclosed in double quotes if the string contains a single quote and no double quotes, otherwise it is enclosed in single quotes. The `print()` function produces a more readable output, by omitting the enclosing quotes and by printing escaped and special characters:

```
>>> "Isn't," they said.'
"Isn't," they said.'
>>> print("Isn't," they said.')
Isn't," they said.
>>> s = 'First line.\nSecond line.' # \n means newline
>>> s # without print(), \n is included in the output
'First line.\nSecond line.'
>>> print(s) # with print(), \n produces a new line
First line.
Second line.
```

If you don't want characters prefaced by `\` to be interpreted as special characters, you can use *raw strings* by adding an `r` before the first quote:

```
>>> print('C:\some\name') # here \n means newline!
C:\some
ame
>>> print(r'C:\some\name') # note the r before the quote
C:\some\name
```

There is one subtle aspect to raw strings: a raw string may not end in an odd number of `\` characters; see [the FAQ entry](#) for more information and workarounds.

String literals can span multiple lines. One way is using triple-quotes: `"""..."""` or `'''...'''`. End of lines are automatically included in the string, but it's possible to prevent this by adding a `\` at the end of the line. The following example:

```
print("""\
Usage: thingy [OPTIONS]
    -h                Display this usage message
    -H hostname       Hostname to connect to
""")
```

produces the following output (note that the initial newline is not included):

```
Usage: thingy [OPTIONS]
```

-h	Display this usage message
-H hostname	Hostname to connect to

Strings can be concatenated (glued together) with the `+` operator, and repeated with `*`:

```
>>> # 3 times 'un', followed by 'ium'
>>> 3 * 'un' + 'ium'
'unununium'
```

Two or more *string literals* (i.e. the ones enclosed between quotes) next to each other are automatically concatenated.

```
>>> 'Py' 'thon'
'Python'
```

This feature is particularly useful when you want to break long strings:

```
>>> text = ('Put several strings within parentheses '
...         'to have them joined together.')
>>> text
'Put several strings within parentheses to have them joined together.'
```

This only works with two literals though, not with variables or expressions:

```
>>> prefix = 'Py'
>>> prefix 'thon' # can't concatenate a variable and a literal
File "<stdin>", line 1
    prefix 'thon'
    ^^^^^^
SyntaxError: invalid syntax
>>> ('un' * 3) 'ium'
File "<stdin>", line 1
    ('un' * 3) 'ium'
    ^^^^^^
SyntaxError: invalid syntax
```

If you want to concatenate variables or a variable and a literal, use `+`:

```
>>> prefix + 'thon'
'Python'
```

Strings can be *indexed* (subscripted), with the first character having index 0. There is no separate character type; a character is simply a string of size one:

```
>>> word = 'Python'
>>> word[0]    # character in position 0
'P'
>>> word[5]    # character in position 5
'n'
```

Indices may also be negative numbers, to start counting from the right:

```
>>> word[-1]   # last character
'n'
>>> word[-2]   # second-last character
'o'
>>> word[-6]
'P'
```

Note that since -0 is the same as 0, negative indices start from -1.

In addition to indexing, *slicing* is also supported. While indexing is used to obtain individual characters, *slicing* allows you to obtain substring:

```
>>> word[0:2]   # characters from position 0 (included) to 2
'Py'
>>> word[2:5]   # characters from position 2 (included) to 5
'tho'
```

Slice indices have useful defaults; an omitted first index defaults to zero, an omitted second index defaults to the size of the string being sliced.

```
>>> word[:2]    # character from the beginning to position 2
'Py'
>>> word[4:]    # characters from position 4 (included) to the end
'on'
```

```
'on'
>>> word[-2:] # characters from the second-last (includ
'on'
```

Note how the start is always included, and the end always excluded. This makes sure that `s[:i] + s[i:]` is always equal to `s`:

```
>>> word[:2] + word[2:]
'Python'
>>> word[:4] + word[4:]
'Python'
```

One way to remember how slices work is to think of the indices as pointing *between* characters, with the left edge of the first character numbered 0. Then the right edge of the last character of a string of  $n$  characters has index  $n$ , for example:

```
+---+---+---+---+---+---+
| P | y | t | h | o | n |
+---+---+---+---+---+---+
0   1   2   3   4   5   6
-6  -5  -4  -3  -2  -1
```

The first row of numbers gives the position of the indices 0...6 in the string; the second row gives the corresponding negative indices. The slice from  $i$  to  $j$  consists of all characters between the edges labeled  $i$  and  $j$ , respectively.

For non-negative indices, the length of a slice is the difference of the indices, if both are within bounds. For example, the length of `word[1:3]` is 2.

Attempting to use an index that is too large will result in an error:

```
>>> word[42] # the word only has 6 characters
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
IndexError: string index out of range
```

However, out of range slice indexes are handled gracefully when used for slicing:

```
>>> word[4:42]
'on'
>>> word[42:]
''
```

Python strings cannot be changed — they are [immutable](#). Therefore, assigning to an indexed position in the string results in an error:

```
>>> word[0] = 'J'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: 'str' object does not support item assignment
>>> word[2:] = 'py'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: 'str' object does not support item assignment
```

If you need a different string, you should create a new one:

```
>>> 'J' + word[1:]
'Jython'
>>> word[:2] + 'py'
'Pypy'
```

The built-in function [len\(\)](#) returns the length of a string:

```
>>> s = 'supercalifragilisticexpialidocious'
>>> len(s)
34
```

String literals that have embedded expressions.

## Format String Syntax

Information about string formatting with `str.format()`.

## printf-style String Formatting

The old formatting operations invoked when strings are the left operand of the `%` operator are described in more detail here.

### 3.1.3. Lists

Python knows a number of *compound* data types, used to group together other values. The most versatile is the *list*, which can be written as a list of comma-separated values (items) between square brackets. Lists might contain items of different types, but usually the items all have the same type.

```
>>> squares = [1, 4, 9, 16, 25]
>>> squares
[1, 4, 9, 16, 25]
```

Like strings (and all other built-in [sequence](#) types), lists can be indexed and sliced:

```
>>> squares[0] # indexing returns the item
1
>>> squares[-1]
25
>>> squares[-3:] # slicing returns a new list
[9, 16, 25]
```

All slice operations return a new list containing the requested elements. This means that the following slice returns a [shallow copy](#) of the list:

```
>>> squares[:]
[1, 4, 9, 16, 25]
```

Lists also support operations like concatenation:

```
>>> squares + [36, 49, 64, 81, 100]
[1, 4, 9, 16, 25, 36, 49, 64, 81, 100]
```

Unlike strings, which are [immutable](#), lists are a [mutable](#) type, i.e. it is possible to change their content:

```
>>> cubes = [1, 8, 27, 65, 125] # something's wrong here
>>> 4 ** 3 # the cube of 4 is 64, not 65!
64
>>> cubes[3] = 64 # replace the wrong value
>>> cubes
[1, 8, 27, 64, 125]
```

You can also add new items at the end of the list, by using the **append()** *method* (we will see more about methods later):

```
>>> cubes.append(216) # add the cube of 6
>>> cubes.append(7 ** 3) # and the cube of 7
>>> cubes
[1, 8, 27, 64, 125, 216, 343]
```

Assignment to slices is also possible, and this can even change the size of the list or clear it entirely:

```
>>> letters = ['a', 'b', 'c', 'd', 'e', 'f', 'g']
>>> letters
['a', 'b', 'c', 'd', 'e', 'f', 'g']
>>> # replace some values
>>> letters[2:5] = ['C', 'D', 'E']
>>> letters
['a', 'b', 'C', 'D', 'E', 'f', 'g']
>>> # now remove them
>>> letters[2:5] = []
>>> letters
['a', 'b', 'f', 'g']
>>> # clear the list by replacing all the elements with
>>> letters[:] = []
>>> letters
```

```
[]
```

The built-in function `len()` also applies to lists:

```
>>> letters = ['a', 'b', 'c', 'd']
>>> len(letters)
4
```

It is possible to nest lists (create lists containing other lists), for example:

```
>>> a = ['a', 'b', 'c']
>>> n = [1, 2, 3]
>>> x = [a, n]
>>> x
[['a', 'b', 'c'], [1, 2, 3]]
>>> x[0]
['a', 'b', 'c']
>>> x[0][1]
'b'
```

## 3.2. First Steps Towards Programming

Of course, we can use Python for more complicated tasks than adding two and two together. For instance, we can write an initial sub-sequence of the [Fibonacci series](https://en.wikipedia.org/wiki/Fibonacci_number) [https://en.wikipedia.org/wiki/Fibonacci\_number] as follows:

```
>>> # Fibonacci series:
... # the sum of two elements defines the next
... a, b = 0, 1
>>> while a < 10:
...     print(a)
...     a, b = b, a+b
...
0
1
1
2
```

3  
5  
8

This example introduces several new features.

- The first line contains a *multiple assignment*: the variables `a` and `b` simultaneously get the new values 0 and 1. On the last line this is used again, demonstrating that the expressions on the right-hand side are all evaluated first before any of the assignments take place. The right-hand side expressions are evaluated from the left to the right.
- The `while` loop executes as long as the condition (here: `a < 10`) remains true. In Python, like in C, any non-zero integer value is true; zero is false. The condition may also be a string or list value, in fact any sequence; anything with a non-zero length is true, empty sequences are false. The test used in the example is a simple comparison. The standard comparison operators are written the same as in C: `<` (less than), `>` (greater than), `==` (equal to), `<=` (less than or equal to), `>=` (greater than or equal to) and `!=` (not equal to).
- The *body* of the loop is *indented*: indentation is Python's way of grouping statements. At the interactive prompt, you have to type a tab or space(s) for each indented line. In practice you will prepare more complicated input for Python with a text editor; all decent text editors have an auto-indent facility. When a compound statement is entered interactively, it must be followed by a blank line to indicate completion (since the parser cannot guess when you have typed the last line). Note that each line within a basic block must be indented by the same amount.
- The `print()` function writes the value of the argument(s) it is given. It differs from just writing the expression you want to write (as we did earlier in the calculator examples) in the way it handles multiple arguments, floating point quantities, and strings. Strings are printed without quotes, and a space is inserted between items, so you can format things nicely, like this:

```
>>> i = 256*256
>>> print('The value of i is', i)
The value of i is 65536
```

The keyword argument *end* can be used to avoid the newline after the output, or end the output with a different string:

```
>>> a, b = 0, 1
>>> while a < 1000:
...     print(a, end=', ')
...     a, b = b, a+b
...
0,1,1,2,3,5,8,13,21,34,55,89,144,233,377,610,987,
```

## Footnotes

1

Since `**` has higher precedence than `-`, `-3**2` will be interpreted as `-(3**2)` and thus result in `-9`. To avoid this and get `9`, you can use `(-3)**2`.

2

Unlike other languages, special characters such as `\n` have the same meaning with both single (`'...'`) and double (`"..."`) quotes. The only difference between the two is that within single quotes you don't need to escape `"` (but you have to escape `\'`) and vice versa.

## 4. More Control Flow Tools

Besides the `while` statement just introduced, Python uses the usual flow control statements known from other languages, with some twists.

### 4.1. `if` Statements

Perhaps the most well-known statement type is the `if` statement. For example:

```
>>> x = int(input("Please enter an integer: "))
Please enter an integer: 42
>>> if x < 0:
...     x = 0
...     print('Negative changed to zero')
... elif x == 0:
...     print('Zero')
... elif x == 1:
...     print('Single')
... else:
...     print('More')
...
More
```

There can be zero or more `elif` parts, and the `else` part is optional. The keyword `‘elif’` is short for ‘else if’, and is useful to avoid excessive indentation. An `if ... elif ... elif ...` sequence is a substitute for the `switch` or `case` statements found in other languages.

If you’re comparing the same value to several constants, or checking for specific types or attributes, you may also find the `match` statement useful. For more details see [match Statements](#).

## 4.2. **for** Statements

The **for** statement in Python differs a bit from what you may be used to in C or Pascal. Rather than always iterating over an arithmetic progression of numbers (like in Pascal), or giving the user the ability to define both the iteration step and halting condition (as C), Python's **for** statement iterates over the items of any sequence (a list or a string), in the order that they appear in the sequence. For example (no pun intended):

```
>>> # Measure some strings:
... words = ['cat', 'window', 'defenestrate']
>>> for w in words:
...     print(w, len(w))
...
cat 3
window 6
defenestrate 12
```

Code that modifies a collection while iterating over that same collection can be tricky to get right. Instead, it is usually more straight-forward to loop over a copy of the collection or to create a new collection:

```
# Create a sample collection
users = {'Hans': 'active', 'Éléonore': 'inactive', '景太郎': 'active'}

# Strategy: Iterate over a copy
for user, status in users.copy().items():
    if status == 'inactive':
        del users[user]

# Strategy: Create a new collection
active_users = {}
for user, status in users.items():
    if status == 'active':
        active_users[user] = status
```

## 4.3. The **range()** Function

If you do need to iterate over a sequence of numbers, the built-in function **range()** comes in handy. It generates arithmetic progressions:

```
>>> for i in range(5):
...     print(i)
...
0
1
2
3
4
```

The given end point is never part of the generated sequence; `range(10)` generates 10 values, the legal indices for items of a sequence of length 10. It is possible to let the range start at another number, or to specify a different increment (even negative; sometimes this is called the ‘step’):

```
>>> list(range(5, 10))
[5, 6, 7, 8, 9]
```

```
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
```

```
>>> list(range(-10, -100, -30))
[-10, -40, -70]
```

To iterate over the indices of a sequence, you can combine **range()** and **len()** as follows:

```
>>> a = ['Mary', 'had', 'a', 'little', 'lamb']
>>> for i in range(len(a)):
...     print(i, a[i])
...
0 Mary
1 had
2 a
3 little
4 lamb
```

In most such cases, however, it is convenient to use the `enumerate()` function, see [Looping Techniques](#).

A strange thing happens if you just print a range:

```
>>> range(10)
range(0, 10)
```

In many ways the object returned by `range()` behaves as if it is a list, but in fact it isn't. It is an object which returns the successive items of the desired sequence when you iterate over it, but it doesn't really make the list, thus saving space.

We say such an object is [iterable](#), that is, suitable as a target for functions and constructs that expect something from which they can obtain successive items until the supply is exhausted. We have seen that the `for` statement is such a construct, while an example of a function that takes an iterable is `sum()`:

```
>>> sum(range(4))    # 0 + 1 + 2 + 3
6
```

Later we will see more functions that return iterables and take iterables as arguments. In chapter [Data Structures](#), we will discuss in more detail about `list()`.

## 4.4. `break` and `continue` Statements, and `else` Clauses on Loops

The `break` statement, like in C, breaks out of the innermost enclosing `for` or `while` loop.

Loop statements may have an `else` clause; it is executed when the loop terminates through exhaustion of the iterable (with `for`) or when the condition becomes false (with `while`), but not when the loop is terminated by a `break` statement. This is exemplified by the following loop, which searches for prime numbers:

```
>>> for n in range(2, 10):
...     for x in range(2, n):
```

```

...         if n % x == 0:
...             print(n, 'equals', x, '*', n//x)
...             break
...     else:
...         # loop fell through without finding a factor
...         print(n, 'is a prime number')
...
2 is a prime number
3 is a prime number
4 equals 2 * 2
5 is a prime number
6 equals 2 * 3
7 is a prime number
8 equals 2 * 4
9 equals 3 * 3

```

(Yes, this is the correct code. Look closely: the `else` clause belongs to the `for` loop, **not** the `if` statement.)

When used with a loop, the `else` clause has more in common with the `else` clause of a `try` statement than it does with that of `if` statements: a `try` statement's `else` clause runs when no exception occurs, and a loop's `else` clause runs when no `break` occurs. For more on the `try` statement and exceptions, see [Handling Exceptions](#).

The `continue` statement, also borrowed from C, continues with the next iteration of the loop:

```

>>> for num in range(2, 10):
...     if num % 2 == 0:
...         print("Found an even number", num)
...         continue
...     print("Found an odd number", num)
...
Found an even number 2
Found an odd number 3
Found an even number 4
Found an odd number 5
Found an even number 6

```

```
Found an odd number 7
Found an even number 8
Found an odd number 9
```

## 4.5. **pass** Statements

The **pass** statement does nothing. It can be used when a statement is required syntactically but the program requires no action. For example:

```
>>> while True:
...     pass # Busy-wait for keyboard interrupt (Ctrl+C)
...
```

This is commonly used for creating minimal classes:

```
>>> class MyEmptyClass:
...     pass
...
```

Another place **pass** can be used is as a place-holder for a function or conditional body when you are working on new code, allowing you to keep thinking at a more abstract level. The **pass** is silently ignored:

```
>>> def initlog(*args):
...     pass # Remember to implement this!
...
```

## 4.6. **match** Statements

A **match** statement takes an expression and compares its value to successive patterns given as one or more case blocks. This is superficially similar to a switch statement in C, Java or JavaScript (and many other languages), but it's more similar to pattern matching in languages like Rust or Haskell. Only the first pattern that matches gets executed and it can also extract components (sequence elements or object attributes) from the value into variables.

The simplest form compares a subject value against one or more literals:

```
def http_error(status):
    match status:
        case 400:
            return "Bad request"
        case 404:
            return "Not found"
        case 418:
            return "I'm a teapot"
        case _:
            return "Something's wrong with the internet"
```

Note the last block: the “variable name” `_` acts as a *wildcard* and never fails to match. If no case matches, none of the branches is executed.

You can combine several literals in a single pattern using `|` (“or”):

```
case 401 | 403 | 404:
    return "Not allowed"
```

Patterns can look like unpacking assignments, and can be used to bind variables:

```
# point is an (x, y) tuple
match point:
    case (0, 0):
        print("Origin")
    case (0, y):
        print(f"Y={y}")
    case (x, 0):
        print(f"X={x}")
    case (x, y):
        print(f"X={x}, Y={y}")
    case _:
        raise ValueError("Not a point")
```

Study that one carefully! The first pattern has two literals, and can

be thought of as an extension of the literal pattern shown above. But the next two patterns combine a literal and a variable, and the variable *binds* a value from the subject (`point`). The fourth pattern captures two values, which makes it conceptually similar to the unpacking assignment `(x, y) = point`.

If you are using classes to structure your data you can use the class name followed by an argument list resembling a constructor, but with the ability to capture attributes into variables:

```
class Point:
    x: int
    y: int

def where_is(point):
    match point:
        case Point(x=0, y=0):
            print("Origin")
        case Point(x=0, y=y):
            print(f"Y={y}")
        case Point(x=x, y=0):
            print(f"X={x}")
        case Point():
            print("Somewhere else")
        case _:
            print("Not a point")
```

You can use positional parameters with some builtin classes that provide an ordering for their attributes (e.g. `dataclasses`). You can also define a specific position for attributes in patterns by setting the `__match_args__` special attribute in your classes. If it's set to `("x", "y")`, the following patterns are all equivalent (and all bind the `y` attribute to the `var` variable):

```
Point(1, var)
Point(1, y=var)
Point(x=1, y=var)
Point(y=var, x=1)
```

A recommended way to read patterns is to look at them as an

extended form of what you would put on the left of an assignment, to understand which variables would be set to what. Only the standalone names (like `var` above) are assigned to by a match statement. Dotted names (like `foo.bar`), attribute names (the `x=` and `y=` above) or class names (recognized by the “(...)” next to them like `Point` above) are never assigned to.

Patterns can be arbitrarily nested. For example, if we have a short list of points, we could match it like this:

```
match points:
    case []:
        print("No points")
    case [Point(0, 0)]:
        print("The origin")
    case [Point(x, y)]:
        print(f"Single point {x}, {y}")
    case [Point(0, y1), Point(0, y2)]:
        print(f"Two on the Y axis at {y1}, {y2}")
    case _:
        print("Something else")
```

We can add an `if` clause to a pattern, known as a “guard”. If the guard is false, `match` goes on to try the next case block. Note that value capture happens before the guard is evaluated:

```
match point:
    case Point(x, y) if x == y:
        print(f"Y=X at {x}")
    case Point(x, y):
        print(f"Not on the diagonal")
```

Several other key features of this statement:

- Like unpacking assignments, tuple and list patterns have exactly the same meaning and actually match arbitrary sequences. An important exception is that they don’t match iterators or strings.
- Sequence patterns support extended unpacking: `[x, y,`

`*rest]` and `(x, y, *rest)` work similar to unpacking assignments. The name after `*` may also be `_`, so `(x, y, *)` matches a sequence of at least two items without binding the remaining items.

- Mapping patterns: `{"bandwidth": b, "latency": l}` captures the "bandwidth" and "latency" values from a dictionary. Unlike sequence patterns, extra keys are ignored. An unpacking like `**rest` is also supported. (But `**_` would be redundant, so it is not allowed.)
- Subpatterns may be captured using the `as` keyword:

```
case (Point(x1, y1), Point(x2, y2) as p2): ...
```

will capture the second element of the input as `p2` (as long as the input is a sequence of two points)

- Most literals are compared by equality, however the singletons `True`, `False` and `None` are compared by identity.
- Patterns may use named constants. These must be dotted names to prevent them from being interpreted as capture variable:

```
from enum import Enum
class Color(Enum):
    RED = 'red'
    GREEN = 'green'
    BLUE = 'blue'
```

```
color = Color(input("Enter your choice of 'red', 'b
```

```
match color:
    case Color.RED:
        print("I see red!")
    case Color.GREEN:
        print("Grass is green")
    case Color.BLUE:
```

```
print("I'm feeling the blues :(")
```

For a more detailed explanation and additional examples, you can look into [PEP 636](https://peps.python.org/pep-0636/) [https://peps.python.org/pep-0636/] which is written in a tutorial format.

## 4.7. Defining Functions

We can create a function that writes the Fibonacci series to an arbitrary boundary:

```
>>> def fib(n):      # write Fibonacci series up to n
...     """Print a Fibonacci series up to n."""
...     a, b = 0, 1
...     while a < n:
...         print(a, end=' ')
...         a, b = b, a+b
...     print()
...
>>> # Now call the function we just defined:
... fib(2000)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987 1597
```

The keyword `def` introduces a function *definition*. It must be followed by the function name and the parenthesized list of formal parameters. The statements that form the body of the function start at the next line, and must be indented.

The first statement of the function body can optionally be a string literal; this string literal is the function's documentation string, or *docstring*. (More about docstrings can be found in the section [Documentation Strings](#).) There are tools which use docstrings to automatically produce online or printed documentation, or to let the user interactively browse through code; it's good practice to include docstrings in code that you write, so make a habit of it.

The *execution* of a function introduces a new symbol table used for the local variables of the function. More precisely, all variable assignments in a function store the value in the local symbol table; whereas variable references first look in the local symbol table, then

in the local symbol tables of enclosing functions, then in the global symbol table, and finally in the table of built-in names. Thus, global variables and variables of enclosing functions cannot be directly assigned a value within a function (unless, for global variables, named in a `global` statement, or, for variables of enclosing functions, named in a `nonlocal` statement), although they may be referenced.

The actual parameters (arguments) to a function call are introduced in the local symbol table of the called function when it is called; thus, arguments are passed using *call by value* (where the *value* is always an object *reference*, not the value of the object). <sup>1</sup> When a function calls another function, or calls itself recursively, a new local symbol table is created for that call.

A function definition associates the function name with the function object in the current symbol table. The interpreter recognizes the object pointed to by that name as a user-defined function. Other names can also point to that same function object and can also be used to access the function:

```
>>> fib
<function fib at 10042ed0>
>>> f = fib
>>> f(100)
0 1 1 2 3 5 8 13 21 34 55 89
```

Coming from other languages, you might object that `fib` is not a function but a procedure since it doesn't return a value. In fact, even functions without a `return` statement do return a value, albeit a rather boring one. This value is called `None` (it's a built-in name). Writing the value `None` is normally suppressed by the interpreter if it would be the only value written. You can see it if you really want to using `print()`:

```
>>> fib(0)
>>> print(fib(0))
None
```

It is simple to write a function that returns a list of the numbers of the Fibonacci series, instead of printing it:

```

>>> def fib2(n): # return Fibonacci series up to n
...     """Return a list containing the Fibonacci series up to n"""
...     result = []
...     a, b = 0, 1
...     while a < n:
...         result.append(a) # see below
...         a, b = b, a+b
...     return result
...
>>> f100 = fib2(100) # call it
>>> f100 # write the result
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]

```

This example, as usual, demonstrates some new Python features:

- The **return** statement returns with a value from a function. **return** without an expression argument returns `None`. Falling off the end of a function also returns `None`.
- The statement `result.append(a)` calls a *method* of the list object `result`. A method is a function that ‘belongs’ to an object and is named `obj.methodname`, where `obj` is some object (this may be an expression), and `methodname` is the name of a method that is defined by the object’s type. Different types define different methods. Methods of different types may have the same name without causing ambiguity. (It is possible to define your own object types and methods, using *classes*, see [Classes](#)) The method **append()** shown in the example is defined for list objects; it adds a new element at the end of the list. In this example it is equivalent to `result = result + [a]`, but more efficient.

## 4.8. More on Defining Functions

It is also possible to define functions with a variable number of arguments. There are three forms, which can be combined.

### 4.8.1. Default Argument Values

The most useful form is to specify a default value for one or more

arguments. This creates a function that can be called with fewer arguments than it is defined to allow. For example:

```
def ask_ok(prompt, retries=4, reminder='Please try again')
    while True:
        ok = input(prompt)
        if ok in ('y', 'ye', 'yes'):
            return True
        if ok in ('n', 'no', 'nop', 'nope'):
            return False
        retries = retries - 1
        if retries < 0:
            raise ValueError('invalid user response')
    print(reminder)
```

This function can be called in several ways:

- giving only the mandatory argument: `ask_ok('Do you really want to quit?')`
- giving one of the optional arguments: `ask_ok('OK to overwrite the file?', 2)`
- or even giving all arguments: `ask_ok('OK to overwrite the file?', 2, 'Come on, only yes or no!')`

This example also introduces the `in` keyword. This tests whether or not a sequence contains a certain value.

The default values are evaluated at the point of function definition in the *defining* scope, so that

```
i = 5
```

```
def f(arg=i):
    print(arg)
```

```
i = 6
f()
```

will print 5.

**Important warning:** The default value is evaluated only once. This

makes a difference when the default is a mutable object such as a list, dictionary, or instances of most classes. For example, the following function accumulates the arguments passed to it on subsequent calls:

```
def f(a, L=[]):  
    L.append(a)  
    return L
```

```
print(f(1))  
print(f(2))  
print(f(3))
```

This will print

```
[1]  
[1, 2]  
[1, 2, 3]
```

If you don't want the default to be shared between subsequent calls, you can write the function like this instead:

```
def f(a, L=None):  
    if L is None:  
        L = []  
    L.append(a)  
    return L
```

## 4.8.2. Keyword Arguments

Functions can also be called using [keyword arguments](#) of the form `kwarg=value`. For instance, the following function:

```
def parrot(voltage, state='a stiff', action='vroom', type='parrot'):  
    print("-- This parrot wouldn't", action, end=' ')  
    print("if you put", voltage, "volts through it.")  
    print("-- Lovely plumage, the", type)  
    print("-- It's", state, "!")
```

accepts one required argument (`voltage`) and three optional

`arguments` (state, action, and type). This function can be called in any of the following ways:

```
parrot(1000) #
parrot(voltage=1000) #
parrot(voltage=1000000, action='VOOOOOM') #
parrot(action='VOOOOOM', voltage=1000000) #
parrot('a million', 'bereft of life', 'jump') #
parrot('a thousand', state='pushing up the daisies') #
```

but all the following calls would be invalid:

```
parrot() # required argument missing
parrot(voltage=5.0, 'dead') # non-keyword argument after
parrot(110, voltage=220) # duplicate value for the s
parrot(actor='John Cleese') # unknown keyword argument
```

In a function call, keyword arguments must follow positional arguments. All the keyword arguments passed must match one of the arguments accepted by the function (e.g. `actor` is not a valid argument for the `parrot` function), and their order is not important. This also includes non-optional arguments (e.g. `parrot(voltage=1000)` is valid too). No argument may receive a value more than once. Here's an example that fails due to this restriction:

```
>>> def function(a):
...     pass
...
>>> function(0, a=0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: function() got multiple values for argument 'a'
```

When a final formal parameter of the form `**name` is present, it receives a dictionary (see [Mapping Types — dict](#)) containing all keyword arguments except for those corresponding to a formal parameter. This may be combined with a formal parameter of the form `*name` (described in the next subsection) which receives a [tuple](#) containing the positional arguments beyond the formal

parameter list. (\*name must occur before \*\*name.) For example, if we define a function like this:

```
def cheeseshop(kind, *arguments, **keywords):
    print("-- Do you have any", kind, "?")
    print("-- I'm sorry, we're all out of", kind)
    for arg in arguments:
        print(arg)
    print("-" * 40)
    for kw in keywords:
        print(kw, ":", keywords[kw])
```

It could be called like this:

```
cheeseshop("Limburger", "It's very runny, sir.",
           "It's really very, VERY runny, sir.",
           shopkeeper="Michael Palin",
           client="John Cleese",
           sketch="Cheese Shop Sketch")
```

and of course it would print:

```
-- Do you have any Limburger ?
-- I'm sorry, we're all out of Limburger
It's very runny, sir.
It's really very, VERY runny, sir.
-----
shopkeeper : Michael Palin
client : John Cleese
sketch : Cheese Shop Sketch
```

Note that the order in which the keyword arguments are printed is guaranteed to match the order in which they were provided in the function call.

### 4.8.3. Special parameters

By default, arguments may be passed to a Python function either by position or explicitly by keyword. For readability and performance, it makes sense to restrict the way arguments can be passed so that a

developer need only look at the function definition to determine if items are passed by position, by position or keyword, or by keyword.

A function definition may look like:

```
def f(pos1, pos2, /, pos_or_kwd, *, kwd1, kwd2):
    -----
    |           |           |
    |           | Positional or keyword |
    |           |           |
    |           |           | - Keyword only
    |           |           |
    -- Positional only
```

where / and \* are optional. If used, these symbols indicate the kind of parameter by how the arguments may be passed to the function: positional-only, positional-or-keyword, and keyword-only. Keyword parameters are also referred to as named parameters.

#### 4.8.3.1. Positional-or-Keyword Arguments

If `/` and `*` are not present in the function definition, arguments may be passed to a function by position or by keyword.

#### 4.8.3.2. Positional-Only Parameters

Looking at this in a bit more detail, it is possible to mark certain parameters as *positional-only*. If *positional-only*, the parameters' order matters, and the parameters cannot be passed by keyword. Positional-only parameters are placed before a `/` (forward-slash). The `/` is used to logically separate the positional-only parameters from the rest of the parameters. If there is no `/` in the function definition, there are no positional-only parameters.

Parameters following the / may be *positional-or-keyword* or *keyword-only*.

#### 4.8.3.3. Keyword-Only Arguments

To mark parameters as *keyword-only*, indicating the parameters must be passed by keyword argument, place an `*` in the arguments

list just before the first *keyword-only* parameter.

#### 4.8.3.4. Function Examples

Consider the following example function definitions paying close attention to the markers `/` and `*`:

```
>>> def standard_arg(arg):
...     print(arg)
...
>>> def pos_only_arg(arg, /):
...     print(arg)
...
>>> def kwd_only_arg(*, arg):
...     print(arg)
...
>>> def combined_example(pos_only, /, standard, *, kwd_only):
...     print(pos_only, standard, kwd_only)
```

The first function definition, `standard_arg`, the most familiar form, places no restrictions on the calling convention and arguments may be passed by position or keyword:

```
>>> standard_arg(2)
2
```

```
>>> standard_arg(arg=2)
2
```

The second function `pos_only_arg` is restricted to only use positional parameters as there is a `/` in the function definition:

```
>>> pos_only_arg(1)
1
```

```
>>> pos_only_arg(arg=1)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: pos_only_arg() got some positional-only arguments
```

The third function `kwd_only_args` only allows keyword arguments as indicated by a `*` in the function definition:

```
>>> kwd_only_arg(3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: kwd_only_arg() takes 0 positional arguments b

>>> kwd_only_arg(arg=3)
3
```

And the last uses all three calling conventions in the same function definition:

```
>>> combined_example(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: combined_example() takes 2 positional argumen

>>> combined_example(1, 2, kwd_only=3)
1 2 3

>>> combined_example(1, standard=2, kwd_only=3)
1 2 3
```

```
>>> combined_example(pos_only=1, standard=2, kwd_only=3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: combined_example() got some positional-only a
```

Finally, consider this function definition which has a potential collision between the positional argument `name` and `**kwargs` which has `name` as a key:

```
def foo(name, **kwargs):
    return 'name' in kwargs
```

There is no possible call that will make it return `True` as the keyword `'name'` will always bind to the first parameter. For example:

```
>>> foo(1, **{'name': 2})
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: foo() got multiple values for argument 'name'
>>>
```

But using `/` (positional only arguments), it is possible since it allows `name` as a positional argument and `'name'` as a key in the keyword arguments:

```
>>> def foo(name, /, **kwds):
...     return 'name' in kwds
...
>>> foo(1, **{'name': 2})
True
```

In other words, the names of positional-only parameters can be used in `**kwds` without ambiguity.

#### 4.8.3.5. Recap

The use case will determine which parameters to use in the function definition:

```
def f(pos1, pos2, /, pos_or_kwd, *, kwd1, kwd2):
```

As guidance:

- Use positional-only if you want the name of the parameters to not be available to the user. This is useful when parameter names have no real meaning, if you want to enforce the order of the arguments when the function is called or if you need to take some positional parameters and arbitrary keywords.
- Use keyword-only when names have meaning and the function definition is more understandable by being explicit with names or you want to prevent users relying on the position of the argument being passed.
- For an API, use positional-only to prevent breaking API changes if the parameter's name is modified in the future.

## 4.8.4. Arbitrary Argument Lists

Finally, the least frequently used option is to specify that a function can be called with an arbitrary number of arguments. These arguments will be wrapped up in a tuple (see [Tuples and Sequences](#)). Before the variable number of arguments, zero or more normal arguments may occur.

```
def write_multiple_items(file, separator, *args):
    file.write(separator.join(args))
```

Normally, these *variadic* arguments will be last in the list of formal parameters, because they scoop up all remaining input arguments that are passed to the function. Any formal parameters which occur after the `*args` parameter are ‘keyword-only’ arguments, meaning that they can only be used as keywords rather than positional arguments.

```
>>> def concat(*args, sep="/"):
...     return sep.join(args)
...
>>> concat("earth", "mars", "venus")
'earth/mars/venus'
>>> concat("earth", "mars", "venus", sep=".")
'earth.mars.venus'
```

## 4.8.5. Unpacking Argument Lists

The reverse situation occurs when the arguments are already in a list or tuple but need to be unpacked for a function call requiring separate positional arguments. For instance, the built-in [range\(\)](#) function expects separate *start* and *stop* arguments. If they are not available separately, write the function call with the `*`-operator to unpack the arguments out of a list or tuple:

```
>>> list(range(3, 6))                # normal call with separate arguments
[3, 4, 5]
>>> args = [3, 6]
>>> list(range(*args))               # call with arguments in a list
[3, 4, 5]
```

In the same fashion, dictionaries can deliver keyword arguments with the `**`-operator:

```
>>> def parrot(voltage, state='a stiff', action='vroom'):  
...     print("-- This parrot wouldn't", action, end=' ')  
...     print("if you put", voltage, "volts through it.")  
...     print("E's", state, "!")  
...  
>>> d = {"voltage": "four million", "state": "bleedin' c  
>>> parrot(**d)  
-- This parrot wouldn't VROOM if you put four million vol
```

### 4.8.6. Lambda Expressions

Small anonymous functions can be created with the `lambda` keyword. This function returns the sum of its two arguments: `lambda a, b: a+b`. Lambda functions can be used wherever function objects are required. They are syntactically restricted to a single expression. Semantically, they are just syntactic sugar for a normal function definition. Like nested function definitions, lambda functions can reference variables from the containing scope:

```
>>> def make_incrementor(n):  
...     return lambda x: x + n  
...  
>>> f = make_incrementor(42)  
>>> f(0)  
42  
>>> f(1)  
43
```

The above example uses a lambda expression to return a function. Another use is to pass a small function as an argument:

```
>>> pairs = [(1, 'one'), (2, 'two'), (3, 'three'), (4, 'four')]  
>>> pairs.sort(key=lambda pair: pair[1])  
>>> pairs  
[(4, 'four'), (1, 'one'), (3, 'three'), (2, 'two')]
```

### 4.8.7. Documentation Strings

Here are some conventions about the content and formatting of documentation strings.

The first line should always be a short, concise summary of the object's purpose. For brevity, it should not explicitly state the object's name or type, since these are available by other means (except if the name happens to be a verb describing a function's operation). This line should begin with a capital letter and end with a period.

If there are more lines in the documentation string, the second line should be blank, visually separating the summary from the rest of the description. The following lines should be one or more paragraphs describing the object's calling conventions, its side effects, etc.

The Python parser does not strip indentation from multi-line string literals in Python, so tools that process documentation have to strip indentation if desired. This is done using the following convention. The first non-blank line *after* the first line of the string determines the amount of indentation for the entire documentation string. (We can't use the first line since it is generally adjacent to the string's opening quotes so its indentation is not apparent in the string literal.) Whitespace "equivalent" to this indentation is then stripped from the start of all lines of the string. Lines that are indented less should not occur, but if they occur all their leading whitespace should be stripped. Equivalence of whitespace should be tested after expansion of tabs (to 8 spaces, normally).

Here is an example of a multi-line docstring:

```
>>> def my_function():
...     """Do nothing, but document it.
...
...     No, really, it doesn't do anything.
...     """
...     pass
...
>>> print(my_function.__doc__)
Do nothing, but document it.
```

No, really, it doesn't do anything.

### 4.8.8. Function Annotations

**Function annotations** are completely optional metadata information about the types used by user-defined functions (see [PEP 3107](https://peps.python.org/pep-3107/) [<https://peps.python.org/pep-3107/>] and [PEP 484](https://peps.python.org/pep-0484/) [<https://peps.python.org/pep-0484/>] for more information).

**Annotations** are stored in the `__annotations__` attribute of the function as a dictionary and have no effect on any other part of the function. Parameter annotations are defined by a colon after the parameter name, followed by an expression evaluating to the value of the annotation. Return annotations are defined by a literal `->`, followed by an expression, between the parameter list and the colon denoting the end of the `def` statement. The following example has a required argument, an optional argument, and the return value annotated:

```
>>> def f(ham: str, eggs: str = 'eggs') -> str:
...     print("Annotations:", f.__annotations__)
...     print("Arguments:", ham, eggs)
...     return ham + ' and ' + eggs
...
>>> f('spam')
Annotations: {'ham': <class 'str'>, 'return': <class 'str'>}
Arguments: spam eggs
'spam and eggs'
```

## 4.9. Intermezzo: Coding Style

Now that you are about to write longer, more complex pieces of Python, it is a good time to talk about *coding style*. Most languages can be written (or more concise, *formatted*) in different styles; some are more readable than others. Making it easy for others to read your code is always a good idea, and adopting a nice coding style helps tremendously for that.

For Python, [PEP 8](https://peps.python.org/pep-0008/) [https://peps.python.org/pep-0008/] has emerged as the style guide that most projects adhere to; it promotes a very readable and eye-pleasing coding style. Every Python developer should read it at some point; here are the most important points extracted for you:

- Use 4-space indentation, and no tabs.

4 spaces are a good compromise between small indentation (allows greater nesting depth) and large indentation (easier to read). Tabs introduce confusion, and are best left out.

- Wrap lines so that they don't exceed 79 characters.

This helps users with small displays and makes it possible to have several code files side-by-side on larger displays.

- Use blank lines to separate functions and classes, and larger blocks of code inside functions.
- When possible, put comments on a line of their own.
- Use docstrings.
- Use spaces around operators and after commas, but not directly inside bracketing constructs: `a = f(1, 2) + g(3, 4)`.
- Name your classes and functions consistently; the convention is to use `UpperCamelCase` for classes and `lowercase_with_underscores` for functions and methods. Always use `self` as the name for the first method argument (see [A First Look at Classes](#) for more on classes and methods).
- Don't use fancy encodings if your code is meant to be used in international environments. Python's default, UTF-8, or even plain ASCII work best in any case.
- Likewise, don't use non-ASCII characters in identifiers if there is only the slightest chance people speaking a different language will read or maintain the code.

## Footnotes

1

Actually, *call by object reference* would be a better description, since if a mutable object is passed, the caller will see any changes the callee makes to it (items inserted into a list).

## 5. Data Structures

This chapter describes some things you've learned about already in more detail, and adds some new things as well.

### 5.1. More on Lists

The list data type has some more methods. Here are all of the methods of list objects:

`list.append(x)`

Add an item to the end of the list. Equivalent to  
`a[len(a):] = [x]`.

`list.extend(iterable)`

Extend the list by appending all the items from the iterable.  
Equivalent to `a[len(a):] = iterable`.

`list.insert(i, x)`

Insert an item at a given position. The first argument is the index of the element before which to insert, so  
`a.insert(0, x)` inserts at the front of the list, and  
`a.insert(len(a), x)` is equivalent to `a.append(x)`.

`list.remove(x)`

Remove the first item from the list whose value is equal to *x*.  
It raises a **ValueError** if there is no such item.

`list.pop([i])`

Remove the item at the given position in the list, and return it. If no index is specified, `a.pop()` removes and returns the last item in the list. (The square brackets around the *i* in the method signature denote that the parameter is optional, not

that you should type square brackets at that position. You will see this notation frequently in the Python Library Reference.)

`list.clear()`

Remove all items from the list. Equivalent to `del a[:]`.

`list.index(x[, start[, end]])`

Return zero-based index in the list of the first item whose value is equal to *x*. Raises a **ValueError** if there is no such item.

The optional arguments *start* and *end* are interpreted as in the slice notation and are used to limit the search to a particular subsequence of the list. The returned index is computed relative to the beginning of the full sequence rather than the *start* argument.

`list.count(x)`

Return the number of times *x* appears in the list.

`list.sort(*, key=None, reverse=False)`

Sort the items of the list in place (the arguments can be used for sort customization, see **sorted()** for their explanation).

`list.reverse()`

Reverse the elements of the list in place.

`list.copy()`

Return a shallow copy of the list. Equivalent to `a[:]`.

An example that uses most of the list methods:

```
>>> fruits = ['orange', 'apple', 'pear', 'banana', 'kiwi']
>>> fruits.count('apple')
2
>>> fruits.count('tangerine')
```

```
0
```

```
>>> fruits.index('banana')
```

```
3
```

```
>>> fruits.index('banana', 4) # Find next banana starting
```

```
6
```

```
>>> fruits.reverse()
```

```
>>> fruits
```

```
['banana', 'apple', 'kiwi', 'banana', 'pear', 'apple', '']
```

```
>>> fruits.append('grape')
```

```
>>> fruits
```

```
['banana', 'apple', 'kiwi', 'banana', 'pear', 'apple', '']
```

```
>>> fruits.sort()
```

```
>>> fruits
```

```
['apple', 'apple', 'banana', 'banana', 'grape', 'kiwi', '']
```

```
>>> fruits.pop()
```

```
'pear'
```

You might have noticed that methods like `insert`, `remove` or `sort` that only modify the list have no return value printed – they return the default `None`. <sup>1</sup> This is a design principle for all mutable data structures in Python.

Another thing you might notice is that not all data can be sorted or compared. For instance, `[None, 'hello', 10]` doesn't sort because integers can't be compared to strings and *None* can't be compared to other types. Also, there are some types that don't have a defined ordering relation. For example, `3+4j < 5+7j` isn't a valid comparison.

### 5.1.1. Using Lists as Stacks

The list methods make it very easy to use a list as a stack, where the last element added is the first element retrieved (“last-in, first-out”). To add an item to the top of the stack, use **`append()`**. To retrieve an item from the top of the stack, use **`pop()`** without an explicit index. For example:

```
>>> stack = [3, 4, 5]
```

```
>>> stack.append(6)
```

```
>>> stack.append(7)
```

```
>>> stack
[3, 4, 5, 6, 7]
>>> stack.pop()
7
>>> stack
[3, 4, 5, 6]
>>> stack.pop()
6
>>> stack.pop()
5
>>> stack
[3, 4]
```

### 5.1.2. Using Lists as Queues

It is also possible to use a list as a queue, where the first element added is the first element retrieved (“first-in, first-out”); however, lists are not efficient for this purpose. While appends and pops from the end of list are fast, doing inserts or pops from the beginning of a list is slow (because all of the other elements have to be shifted by one).

To implement a queue, use `collections.deque` which was designed to have fast appends and pops from both ends. For example:

```
>>> from collections import deque
>>> queue = deque(["Eric", "John", "Michael"])
>>> queue.append("Terry")           # Terry arrives
>>> queue.append("Graham")         # Graham arrives
>>> queue.popleft()                 # The first to arrive now leaves
'Eric'
>>> queue.popleft()                 # The second to arrive now leaves
'John'
>>> queue                           # Remaining queue in order of arrival
deque(['Michael', 'Terry', 'Graham'])
```

### 5.1.3. List Comprehensions

List comprehensions provide a concise way to create lists. Common applications are to make new lists where each element is the result of some operations applied to each member of another sequence or iterable, or to create a subsequence of those elements that satisfy a certain condition.

For example, assume we want to create a list of squares, like:

```
>>> squares = []
>>> for x in range(10):
...     squares.append(x**2)
...
>>> squares
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

Note that this creates (or overwrites) a variable named `x` that still exists after the loop completes. We can calculate the list of squares without any side effects using:

```
squares = list(map(lambda x: x**2, range(10)))
```

or, equivalently:

```
squares = [x**2 for x in range(10)]
```

which is more concise and readable.

A list comprehension consists of brackets containing an expression followed by a **for** clause, then zero or more **for** or **if** clauses. The result will be a new list resulting from evaluating the expression in the context of the **for** and **if** clauses which follow it. For example, this listcomp combines the elements of two lists if they are not equal:

```
>>> [(x, y) for x in [1,2,3] for y in [3,1,4] if x != y]
[(1, 3), (1, 4), (2, 3), (2, 1), (2, 4), (3, 1), (3, 4)]
```

and it's equivalent to:

```
>>> combs = []
>>> for x in [1,2,3]:
```

```

...     for y in [3,1,4]:
...         if x != y:
...             combs.append((x, y))
...
>>> combs
[(1, 3), (1, 4), (2, 3), (2, 1), (2, 4), (3, 1), (3, 4)]

```

Note how the order of the **for** and **if** statements is the same in both these snippets.

If the expression is a tuple (e.g. the `(x, y)` in the previous example), it must be parenthesized.

```

>>> vec = [-4, -2, 0, 2, 4]
>>> # create a new list with the values doubled
>>> [x*2 for x in vec]
[-8, -4, 0, 4, 8]
>>> # filter the list to exclude negative numbers
>>> [x for x in vec if x >= 0]
[0, 2, 4]
>>> # apply a function to all the elements
>>> [abs(x) for x in vec]
[4, 2, 0, 2, 4]
>>> # call a method on each element
>>> freshfruit = [' banana', ' loganberry ', 'passion fruit']
>>> [weapon.strip() for weapon in freshfruit]
['banana', 'loganberry', 'passion fruit']
>>> # create a list of 2-tuples like (number, square)
>>> [(x, x**2) for x in range(6)]
[(0, 0), (1, 1), (2, 4), (3, 9), (4, 16), (5, 25)]
>>> # the tuple must be parenthesized, otherwise an error is raised
>>> [x, x**2 for x in range(6)]
File "<stdin>", line 1
    [x, x**2 for x in range(6)]
    ^^^^^^^

```

SyntaxError: did you forget parentheses around the comprehension expression?

```

>>> # flatten a list using a listcomp with two 'for'
>>> vec = [[1,2,3], [4,5,6], [7,8,9]]
>>> [num for elem in vec for num in elem]

```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

List comprehensions can contain complex expressions and nested functions:

```
>>> from math import pi
>>> [str(round(pi, i)) for i in range(1, 6)]
['3.1', '3.14', '3.142', '3.1416', '3.14159']
```

### 5.1.4. Nested List Comprehensions

The initial expression in a list comprehension can be any arbitrary expression, including another list comprehension.

Consider the following example of a 3x4 matrix implemented as a list of 3 lists of length 4:

```
>>> matrix = [
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12],
... ]
```

The following list comprehension will transpose rows and columns:

```
>>> [[row[i] for row in matrix] for i in range(4)]
[[1, 5, 9], [2, 6, 10], [3, 7, 11], [4, 8, 12]]
```

As we saw in the previous section, the inner list comprehension is evaluated in the context of the **for** that follows it, so this example is equivalent to:

```
>>> transposed = []
>>> for i in range(4):
...     transposed.append([row[i] for row in matrix])
...
>>> transposed
[[1, 5, 9], [2, 6, 10], [3, 7, 11], [4, 8, 12]]
```

which, in turn, is the same as:

```

>>> transposed = []
>>> for i in range(4):
...     # the following 3 lines implement the nested list
...     transposed_row = []
...     for row in matrix:
...         transposed_row.append(row[i])
...     transposed.append(transposed_row)
...
>>> transposed
[[1, 5, 9], [2, 6, 10], [3, 7, 11], [4, 8, 12]]

```

In the real world, you should prefer built-in functions to complex flow statements. The `zip()` function would do a great job for this use case:

```

>>> list(zip(*matrix))
[(1, 5, 9), (2, 6, 10), (3, 7, 11), (4, 8, 12)]

```

See [Unpacking Argument Lists](#) for details on the asterisk in this line.

## 5.2. The `del` statement

There is a way to remove an item from a list given its index instead of its value: the `del` statement. This differs from the `pop()` method which returns a value. The `del` statement can also be used to remove slices from a list or clear the entire list (which we did earlier by assignment of an empty list to the slice). For example:

```

>>> a = [-1, 1, 66.25, 333, 333, 1234.5]
>>> del a[0]
>>> a
[1, 66.25, 333, 333, 1234.5]
>>> del a[2:4]
>>> a
[1, 66.25, 1234.5]
>>> del a[:]
>>> a
[]

```

`del` can also be used to delete entire variables:

```
>>> del a
```

Referencing the name `a` hereafter is an error (at least until another value is assigned to it). We'll find other uses for `del` later.

## 5.3. Tuples and Sequences

We saw that lists and strings have many common properties, such as indexing and slicing operations. They are two examples of *sequence* data types (see [Sequence Types — list, tuple, range](#)). Since Python is an evolving language, other sequence data types may be added. There is also another standard sequence data type: the *tuple*.

A tuple consists of a number of values separated by commas, for instance:

```
>>> t = 12345, 54321, 'hello!'
>>> t[0]
12345
>>> t
(12345, 54321, 'hello!')
>>> # Tuples may be nested:
... u = t, (1, 2, 3, 4, 5)
>>> u
((12345, 54321, 'hello!'), (1, 2, 3, 4, 5))
>>> # Tuples are immutable:
... t[0] = 88888
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: 'tuple' object does not support item assignment
>>> # but they can contain mutable objects:
... v = ([1, 2, 3], [3, 2, 1])
>>> v
([1, 2, 3], [3, 2, 1])
```

As you see, on output tuples are always enclosed in parentheses, so that nested tuples are interpreted correctly; they may be input with

or without surrounding parentheses, although often parentheses are necessary anyway (if the tuple is part of a larger expression). It is not possible to assign to the individual items of a tuple, however it is possible to create tuples which contain mutable objects, such as lists.

Though tuples may seem similar to lists, they are often used in different situations and for different purposes. Tuples are [immutable](#), and usually contain a heterogeneous sequence of elements that are accessed via unpacking (see later in this section) or indexing (or even by attribute in the case of [namedtuples](#)). Lists are [mutable](#), and their elements are usually homogeneous and are accessed by iterating over the list.

A special problem is the construction of tuples containing 0 or 1 items: the syntax has some extra quirks to accommodate these. Empty tuples are constructed by an empty pair of parentheses; a tuple with one item is constructed by following a value with a comma (it is not sufficient to enclose a single value in parentheses). Ugly, but effective. For example:

```
>>> empty = ()
>>> singleton = 'hello',      # <-- note trailing comma
>>> len(empty)
0
>>> len(singleton)
1
>>> singleton
('hello',)
```

The statement `t = 12345, 54321, 'hello!'` is an example of *tuple packing*: the values 12345, 54321 and 'hello!' are packed together in a tuple. The reverse operation is also possible:

```
>>> x, y, z = t
```

This is called, appropriately enough, *sequence unpacking* and works for any sequence on the right-hand side. Sequence unpacking requires that there are as many variables on the left side of the equals sign as there are elements in the sequence. Note that multiple assignment is really just a combination of tuple packing

and sequence unpacking.

## 5.4. Sets

Python also includes a data type for *sets*. A set is an unordered collection with no duplicate elements. Basic uses include membership testing and eliminating duplicate entries. Set objects also support mathematical operations like union, intersection, difference, and symmetric difference.

Curly braces or the `set()` function can be used to create sets.

Note: to create an empty set you have to use `set()`, not `{}`; the latter creates an empty dictionary, a data structure that we discuss in the next section.

Here is a brief demonstration:

```
>>> basket = {'apple', 'orange', 'apple', 'pear', 'orange', 'banana'}
>>> print(basket)                                # show that duplicates
{'orange', 'banana', 'pear', 'apple'}
>>> 'orange' in basket                            # fast membership
True
>>> 'crabgrass' in basket
False

>>> # Demonstrate set operations on unique letters from two words
...
>>> a = set('abracadabra')
>>> b = set('alacazam')
>>> a                                           # unique letters
{'a', 'r', 'b', 'c', 'd'}
>>> a - b                                       # letters in a but not in b
{'r', 'd', 'b'}
>>> a | b                                       # letters in a or b
{'a', 'c', 'r', 'd', 'b', 'm', 'z', 'l'}
>>> a & b                                       # letters in both a and b
{'a', 'c'}
>>> a ^ b                                       # letters in a or b but not in both
{'r', 'd', 'b', 'm', 'z', 'l'}
```

Similarly to [list comprehensions](#), set comprehensions are also supported:

```
>>> a = {x for x in 'abracadabra' if x not in 'abc'}
>>> a
{'r', 'd'}
```

## 5.5. Dictionaries

Another useful data type built into Python is the *dictionary* (see [Mapping Types — dict](#)). Dictionaries are sometimes found in other languages as “associative memories” or “associative arrays”. Unlike sequences, which are indexed by a range of numbers, dictionaries are indexed by *keys*, which can be any immutable type; strings and numbers can always be keys. Tuples can be used as keys if they contain only strings, numbers, or tuples; if a tuple contains any mutable object either directly or indirectly, it cannot be used as a key. You can’t use lists as keys, since lists can be modified in place using index assignments, slice assignments, or methods like **`append()`** and **`extend()`**.

It is best to think of a dictionary as a set of *key: value* pairs, with the requirement that the keys are unique (within one dictionary). A pair of braces creates an empty dictionary: `{}`. Placing a comma-separated list of *key:value* pairs within the braces adds initial *key:value* pairs to the dictionary; this is also the way dictionaries are written on output.

The main operations on a dictionary are storing a value with some key and extracting the value given the key. It is also possible to delete a *key:value* pair with `del`. If you store using a key that is already in use, the old value associated with that key is forgotten. It is an error to extract a value using a non-existent key.

Performing `list(d)` on a dictionary returns a list of all the keys used in the dictionary, in insertion order (if you want it sorted, just use `sorted(d)` instead). To check whether a single key is in the dictionary, use the [in](#) keyword.

Here is a small example using a dictionary:

```
>>> tel = {'jack': 4098, 'sape': 4139}
>>> tel['guido'] = 4127
>>> tel
{'jack': 4098, 'sape': 4139, 'guido': 4127}
>>> tel['jack']
4098
>>> del tel['sape']
>>> tel['irv'] = 4127
>>> tel
{'jack': 4098, 'guido': 4127, 'irv': 4127}
>>> list(tel)
['jack', 'guido', 'irv']
>>> sorted(tel)
['guido', 'irv', 'jack']
>>> 'guido' in tel
True
>>> 'jack' not in tel
False
```

The `dict()` constructor builds dictionaries directly from sequences of key-value pairs:

```
>>> dict([('sape', 4139), ('guido', 4127), ('jack', 4098)])
{'sape': 4139, 'guido': 4127, 'jack': 4098}
```

In addition, dict comprehensions can be used to create dictionaries from arbitrary key and value expressions:

```
>>> {x: x**2 for x in (2, 4, 6)}
{2: 4, 4: 16, 6: 36}
```

When the keys are simple strings, it is sometimes easier to specify pairs using keyword arguments:

```
>>> dict(sape=4139, guido=4127, jack=4098)
{'sape': 4139, 'guido': 4127, 'jack': 4098}
```

## 5.6. Looping Techniques

When looping through dictionaries, the key and corresponding value can be retrieved at the same time using the **items()** method.

```
>>> knights = {'gallahad': 'the pure', 'robin': 'the brave'}
>>> for k, v in knights.items():
...     print(k, v)
...
gallahad the pure
robin the brave
```

When looping through a sequence, the position index and corresponding value can be retrieved at the same time using the **enumerate()** function.

```
>>> for i, v in enumerate(['tic', 'tac', 'toe']):
...     print(i, v)
...
0 tic
1 tac
2 toe
```

To loop over two or more sequences at the same time, the entries can be paired with the **zip()** function.

```
>>> questions = ['name', 'quest', 'favorite color']
>>> answers = ['lancelot', 'the holy grail', 'blue']
>>> for q, a in zip(questions, answers):
...     print('What is your {0}? It is {1}'.format(q, a))
...
What is your name? It is lancelot.
What is your quest? It is the holy grail.
What is your favorite color? It is blue.
```

To loop over a sequence in reverse, first specify the sequence in a forward direction and then call the **reversed()** function.

```
>>> for i in reversed(range(1, 10, 2)):
...     print(i)
...
9
7
5
3
1
```

9  
7  
5  
3  
1

To loop over a sequence in sorted order, use the `sorted()` function which returns a new sorted list while leaving the source unaltered.

```
>>> basket = ['apple', 'orange', 'apple', 'pear', 'orange']
>>> for i in sorted(basket):
...     print(i)
...
apple
apple
banana
orange
orange
pear
```

Using `set()` on a sequence eliminates duplicate elements. The use of `sorted()` in combination with `set()` over a sequence is an idiomatic way to loop over unique elements of the sequence in sorted order.

```
>>> basket = ['apple', 'orange', 'apple', 'pear', 'orange']
>>> for f in sorted(set(basket)):
...     print(f)
...
apple
banana
orange
pear
```

It is sometimes tempting to change a list while you are looping over it; however, it is often simpler and safer to create a new list instead.

```
>>> import math
>>> raw_data = [56.2, float('NaN'), 51.7, 55.3, 52.5, 51.0]
```

```
>>> filtered_data = []
>>> for value in raw_data:
...     if not math.isnan(value):
...         filtered_data.append(value)
...
>>> filtered_data
[56.2, 51.7, 55.3, 52.5, 47.8]
```

## 5.7. More on Conditions

The conditions used in `while` and `if` statements can contain any operators, not just comparisons.

The comparison operators `in` and `not in` are membership tests that determine whether a value is in (or not in) a container. The operators `is` and `is not` compare whether two objects are really the same object. All comparison operators have the same priority, which is lower than that of all numerical operators.

Comparisons can be chained. For example, `a < b == c` tests whether `a` is less than `b` and moreover `b` equals `c`.

Comparisons may be combined using the Boolean operators `and` and `or`, and the outcome of a comparison (or of any other Boolean expression) may be negated with `not`. These have lower priorities than comparison operators; between them, `not` has the highest priority and `or` the lowest, so that `A and not B or C` is equivalent to `(A and (not B)) or C`. As always, parentheses can be used to express the desired composition.

The Boolean operators `and` and `or` are so-called *short-circuit* operators: their arguments are evaluated from left to right, and evaluation stops as soon as the outcome is determined. For example, if `A` and `C` are true but `B` is false, `A and B and C` does not evaluate the expression `C`. When used as a general value and not as a Boolean, the return value of a short-circuit operator is the last evaluated argument.

It is possible to assign the result of a comparison or other Boolean expression to a variable. For example,

```
>>> string1, string2, string3 = '', 'Trondheim', 'Hammerfest'
>>> non_null = string1 or string2 or string3
>>> non_null
'Trondheim'
```

Note that in Python, unlike C, assignment inside expressions must be done explicitly with the [walrus operator](#) `:``=`. This avoids a common class of problems encountered in C programs: typing `=` in an expression when `==` was intended.

## 5.8. Comparing Sequences and Other Types

Sequence objects typically may be compared to other objects with the same sequence type. The comparison uses *lexicographical* ordering: first the first two items are compared, and if they differ this determines the outcome of the comparison; if they are equal, the next two items are compared, and so on, until either sequence is exhausted. If two items to be compared are themselves sequences of the same type, the lexicographical comparison is carried out recursively. If all items of two sequences compare equal, the sequences are considered equal. If one sequence is an initial sub-sequence of the other, the shorter sequence is the smaller (lesser) one. Lexicographical ordering for strings uses the Unicode code point number to order individual characters. Some examples of comparisons between sequences of the same type:

```
(1, 2, 3) < (1, 2, 4)
[1, 2, 3] < [1, 2, 4]
'ABC' < 'C' < 'Pascal' < 'Python'
(1, 2, 3, 4) < (1, 2, 4)
(1, 2) < (1, 2, -1)
(1, 2, 3) == (1.0, 2.0, 3.0)
(1, 2, ('aa', 'ab')) < (1, 2, ('abc', 'a'), 4)
```

Note that comparing objects of different types with `<` or `>` is legal provided that the objects have appropriate comparison methods. For example, mixed numeric types are compared according to their numeric value, so 0 equals 0.0, etc. Otherwise, rather than

providing an arbitrary ordering, the interpreter will raise a `TypeError` exception.

## Footnotes

1

Other languages may return the mutated object, which allows method chaining, such as `d->insert("a")->remove("b")->sort();`.

## 6. Modules

If you quit from the Python interpreter and enter it again, the definitions you have made (functions and variables) are lost. Therefore, if you want to write a somewhat longer program, you are better off using a text editor to prepare the input for the interpreter and running it with that file as input instead. This is known as creating a *script*. As your program gets longer, you may want to split it into several files for easier maintenance. You may also want to use a handy function that you've written in several programs without copying its definition into each program.

To support this, Python has a way to put definitions in a file and use them in a script or in an interactive instance of the interpreter. Such a file is called a *module*; definitions from a module can be *imported* into other modules or into the *main* module (the collection of variables that you have access to in a script executed at the top level and in calculator mode).

A module is a file containing Python definitions and statements. The file name is the module name with the suffix `.py` appended. Within a module, the module's name (as a string) is available as the value of the global variable `__name__`. For instance, use your favorite text editor to create a file called `fibonacci.py` in the current directory with the following contents:

```
# Fibonacci numbers module

def fib(n):    # write Fibonacci series up to n
    a, b = 0, 1
    while a < n:
        print(a, end=' ')
        a, b = b, a+b
    print()

def fib2(n):   # return Fibonacci series up to n
```

```

result = []
a, b = 0, 1
while a < n:
    result.append(a)
    a, b = b, a+b
return result

```

Now enter the Python interpreter and import this module with the following command:

```
>>> import fibo
```

This does not add the names of the functions defined in `fibo` directly to the current [namespace](#) (see [Python Scopes and Namespaces](#) for more details); it only adds the module name `fibo` there. Using the module name you can access the functions:

```

>>> fibo.fib(1000)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987
>>> fibo.fib2(100)
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
>>> fibo.__name__
'fibo'

```

If you intend to use a function often you can assign it to a local name:

```

>>> fib = fibo.fib
>>> fib(500)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377

```

## 6.1. More on Modules

A module can contain executable statements as well as function definitions. These statements are intended to initialize the module. They are executed only the *first* time the module name is encountered in an import statement. <sup>1</sup> (They are also run if the file is executed as a script.)

Each module has its own private namespace, which is used as the

global namespace by all functions defined in the module. Thus, the author of a module can use global variables in the module without worrying about accidental clashes with a user's global variables. On the other hand, if you know what you are doing you can touch a module's global variables with the same notation used to refer to its functions, `modname.itemname`.

Modules can import other modules. It is customary but not required to place all `import` statements at the beginning of a module (or script, for that matter). The imported module names, if placed at the top level of a module (outside any functions or classes), are added to the module's global namespace.

There is a variant of the `import` statement that imports names from a module directly into the importing module's namespace. For example:

```
>>> from fibo import fib, fib2
>>> fib(500)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377
```

This does not introduce the module name from which the imports are taken in the local namespace (so in the example, `fibo` is not defined).

There is even a variant to import all names that a module defines:

```
>>> from fibo import *
>>> fib(500)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377
```

This imports all names except those beginning with an underscore (`_`). In most cases Python programmers do not use this facility since it introduces an unknown set of names into the interpreter, possibly hiding some things you have already defined.

Note that in general the practice of importing `*` from a module or package is frowned upon, since it often causes poorly readable code. However, it is okay to use it to save typing in interactive sessions.

If the module name is followed by **as**, then the name following **as** is bound directly to the imported module.

```
>>> import fibo as fib
>>> fib.fib(500)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377
```

This is effectively importing the module in the same way that `import fibo` will do, with the only difference of it being available as `fib`.

It can also be used when utilising **from** with similar effects:

```
>>> from fibo import fib as fibonacci
>>> fibonacci(500)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377
```

### Note

For efficiency reasons, each module is only imported once per interpreter session. Therefore, if you change your modules, you must restart the interpreter – or, if it's just one module you want to test interactively, use `importlib.reload()`, e.g. `import importlib; importlib.reload(modulename)`.

## 6.1.1. Executing modules as scripts

When you run a Python module with

```
python fibo.py <arguments>
```

the code in the module will be executed, just as if you imported it, but with the `__name__` set to `"__main__"`. That means that by adding this code at the end of your module:

```
if __name__ == "__main__":
    import sys
    fib(int(sys.argv[1]))
```

you can make the file usable as a script as well as an importable

module, because the code that parses the command line only runs if the module is executed as the “main” file:

```
$ python fibo.py 50
0 1 1 2 3 5 8 13 21 34
```

If the module is imported, the code is not run:

```
>>> import fibo
>>>
```

This is often used either to provide a convenient user interface to a module, or for testing purposes (running the module as a script executes a test suite).

### 6.1.2. The Module Search Path

When a module named **spam** is imported, the interpreter first searches for a built-in module with that name. These module names are listed in [sys.builtin\\_module\\_names](#). If not found, it then searches for a file named `spam.py` in a list of directories given by the variable [sys.path](#). [sys.path](#) is initialized from these locations:

- The directory containing the input script (or the current directory when no file is specified).
- [PYTHONPATH](#) (a list of directory names, with the same syntax as the shell variable **PATH**).
- The installation-dependent default (by convention including a `site-packages` directory, handled by the [site](#) module).

More details are at [The initialization of the sys.path module search path](#).

#### Note

On file systems which support symlinks, the directory containing the input script is calculated after the symlink is followed. In other words the directory containing the symlink is **not** added to the module search path.

After initialization, Python programs can modify `sys.path`. The directory containing the script being run is placed at the beginning of the search path, ahead of the standard library path. This means that scripts in that directory will be loaded instead of modules of the same name in the library directory. This is an error unless the replacement is intended. See section [Standard Modules](#) for more information.

### 6.1.3. “Compiled” Python files

To speed up loading modules, Python caches the compiled version of each module in the `__pycache__` directory under the name `module.version.pyc`, where the version encodes the format of the compiled file; it generally contains the Python version number. For example, in CPython release 3.3 the compiled version of `spam.py` would be cached as `__pycache__/spam.cpython-33.pyc`. This naming convention allows compiled modules from different releases and different versions of Python to coexist.

Python checks the modification date of the source against the compiled version to see if it’s out of date and needs to be recompiled. This is a completely automatic process. Also, the compiled modules are platform-independent, so the same library can be shared among systems with different architectures.

Python does not check the cache in two circumstances. First, it always recompiles and does not store the result for the module that’s loaded directly from the command line. Second, it does not check the cache if there is no source module. To support a non-source (compiled only) distribution, the compiled module must be in the source directory, and there must not be a source module.

Some tips for experts:

- You can use the `-O` or `-OO` switches on the Python command to reduce the size of a compiled module. The `-O` switch removes assert statements, the `-OO` switch removes both assert statements and `__doc__` strings. Since some programs may rely on having these available, you should only use this option if you know what you’re doing. “Optimized”

modules have an `opt-` tag and are usually smaller. Future releases may change the effects of optimization.

- A program doesn't run any faster when it is read from a `.pyc` file than when it is read from a `.py` file; the only thing that's faster about `.pyc` files is the speed with which they are loaded.
- The module `compileall` can create `.pyc` files for all modules in a directory.
- There is more detail on this process, including a flow chart of the decisions, in [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/].

## 6.2. Standard Modules

Python comes with a library of standard modules, described in a separate document, the Python Library Reference (“Library Reference” hereafter). Some modules are built into the interpreter; these provide access to operations that are not part of the core of the language but are nevertheless built in, either for efficiency or to provide access to operating system primitives such as system calls. The set of such modules is a configuration option which also depends on the underlying platform. For example, the `winreg` module is only provided on Windows systems. One particular module deserves some attention: `sys`, which is built into every Python interpreter. The variables `sys.ps1` and `sys.ps2` define the strings used as primary and secondary prompts:

```
>>> import sys
>>> sys.ps1
'>>> '
>>> sys.ps2
'... '
>>> sys.ps1 = 'C> '
C> print('Yuck!')
Yuck!
C>
```

These two variables are only defined if the interpreter is in interactive mode.

The variable `sys.path` is a list of strings that determines the

interpreter's search path for modules. It is initialized to a default path taken from the environment variable `PYTHONPATH`, or from a built-in default if `PYTHONPATH` is not set. You can modify it using standard list operations:

```
>>> import sys
>>> sys.path.append('/ufs/guido/lib/python')
```

## 6.3. The `dir()` Function

The built-in function `dir()` is used to find out which names a module defines. It returns a sorted list of strings:

```
>>> import fibo, sys
>>> dir(fibo)
['__name__', 'fib', 'fib2']
>>> dir(sys)
['__breakpointhook__', '__displayhook__', '__doc__', '__file__',
 '__interactivehook__', '__loader__', '__name__', '__package__',
 '__stderr__', '__stdin__', '__stdout__', '__unraisablehook__',
 '_clear_type_cache', '_current_frames', '_debugmallocstats',
 '_getframe', '_git', '_home', '_xoptions', 'abiflags', 'api_version',
 'argv', 'audit', 'base_exec_prefix', 'base_module_searchpath',
 'breakpointhook', 'builtin_module_names', 'byteorder', 'callstats',
 'copyright', 'displayhook', 'dont_write_bytecode', 'excepthook',
 'exec_prefix', 'executable', 'exit', 'float_repr_style', 'get_asyncgen_hooks',
 'get_coroutine_origin_tracking_depth', 'getallocatedblocks',
 'getdefaultencoding', 'getdlopenflags', 'getfilesystemencodeerrors',
 'getfilesystemencoding', 'getrecursionlimit', 'getrefcount', 'getsizeof',
 'getswitchinterval', 'gettrace', 'hash_info', 'hexversion', 'implementation',
 'intern', 'is_finalizing', 'last_traceback', 'last_typeerror',
 'maxsize', 'maxunicode', 'meta_path', 'modules', 'path', 'path_importer_cache',
 'platform', 'prefix', 'ps1', 'ps2', 'set_asyncgen_hooks',
 'set_coroutine_origin_tracking_depth', 'setprofile', 'setrecursionlimit',
 'setswitchinterval', 'stdin', 'stdout', 'thread_info', 'unraisablehook',
 'warnoptions']
```

Without arguments, `dir()` lists the names you have defined currently:

```
>>> a = [1, 2, 3, 4, 5]
>>> import fibo
>>> fib = fibo.fib
>>> dir()
['__builtins__', '__name__', 'a', 'fib', 'fibo', 'sys']
```

Note that it lists all types of names: variables, modules, functions, etc.

`dir()` does not list the names of built-in functions and variables. If you want a list of those, they are defined in the standard module `builtins`:

```
>>> import builtins
>>> dir(builtins)
['ArithmeticError', 'AssertionError', 'AttributeError', 'BlockingIOError', 'BrokenPipeError', 'BufferError', 'ChildProcessError', 'ConnectionAbortedError', 'ConnectionRefusedError', 'ConnectionResetError', 'DeprecationWarning', 'EOFError', 'Ellipsis', 'EnvironmentError', 'Exception', 'FileExistsError', 'FileNotFoundError', 'FloatingPointError', 'FutureWarning', 'GeneratorExit', 'IOError', 'ImportError', 'ImportWarning', 'IndentationError', 'IndexError', 'InterruptedError', 'IsADirectoryError', 'KeyError', 'KeyboardInterrupt', 'MemoryError', 'NameError', 'NoneType', 'NotADirectoryError', 'NotImplementedError', 'OSError', 'OverflowError', 'PendingDeprecationWarning', 'PermissionError', 'ProcessLookupError', 'ReferenceError', 'ResourceWarning', 'RuntimeError', 'StopIteration', 'SyntaxError', 'SyntaxWarning', 'SystemExit', 'SystemError', 'TabError', 'TimeoutError', 'True', 'TypeError', 'UnboundLocalError', 'UnicodeDecodeError', 'UnicodeEncodeError', 'UnicodeError', 'UnicodeTranslateError', 'UnicodeWarning', 'ValueError', 'Warning', 'ZeroDivisionError', '_', '__builtins__', '__debug__', '__doc__', '__import__', '__name__', '__package__', 'all', 'any', 'ascii', 'bin', 'bool', 'bytearray', 'bytes', 'chr', 'classmethod', 'compile', 'complex', 'copyright']
```

```
'delattr', 'dict', 'dir', 'divmod', 'enumerate', 'eval',
'filter', 'float', 'format', 'frozenset', 'getattr', 'g
'hash', 'help', 'hex', 'id', 'input', 'int', 'isinstanc
'iter', 'len', 'license', 'list', 'locals', 'map', 'max
'min', 'next', 'object', 'oct', 'open', 'ord', 'pow', '
'quit', 'range', 'repr', 'reversed', 'round', 'set', 's
'sorted', 'staticmethod', 'str', 'sum', 'super', 'tuple
'zip']
```

## 6.4. Packages

Packages are a way of structuring Python’s module namespace by using “dotted module names”. For example, the module name **A.B** designates a submodule named **B** in a package named **A**. Just like the use of modules saves the authors of different modules from having to worry about each other’s global variable names, the use of dotted module names saves the authors of multi-module packages like NumPy or Pillow from having to worry about each other’s module names.

Suppose you want to design a collection of modules (a “package”) for the uniform handling of sound files and sound data. There are many different sound file formats (usually recognized by their extension, for example: `.wav`, `.aiff`, `.au`), so you may need to create and maintain a growing collection of modules for the conversion between the various file formats. There are also many different operations you might want to perform on sound data (such as mixing, adding echo, applying an equalizer function, creating an artificial stereo effect), so in addition you will be writing a never-ending stream of modules to perform these operations. Here’s a possible structure for your package (expressed in terms of a hierarchical filesystem):

sound/	Top-level package
__init__.py	Initialize the sound package
formats/	Subpackage for file formats
__init__.py	
wavread.py	
wavwrite.py	

```

    aiffread.py
    aiffwrite.py
    auread.py
    auwrite.py
    ...
effects/                               Subpackage for sound effects
    __init__.py
    echo.py
    surround.py
    reverse.py
    ...
filters/                               Subpackage for filters
    __init__.py
    equalizer.py
    vocoder.py
    karaoke.py
    ...

```

When importing the package, Python searches through the directories on `sys.path` looking for the package subdirectory.

The `__init__.py` files are required to make Python treat directories containing the file as packages. This prevents directories with a common name, such as `string`, from unintentionally hiding valid modules that occur later on the module search path. In the simplest case, `__init__.py` can just be an empty file, but it can also execute initialization code for the package or set the `__all__` variable, described later.

Users of the package can import individual modules from the package, for example:

```
import sound.effects.echo
```

This loads the submodule `sound.effects.echo`. It must be referenced with its full name.

```
sound.effects.echo.echofilter(input, output, delay=0.7,
```

An alternative way of importing the submodule is:

```
from sound.effects import echo
```

This also loads the submodule **echo**, and makes it available without its package prefix, so it can be used as follows:

```
echo.echofilter(input, output, delay=0.7, atten=4)
```

Yet another variation is to import the desired function or variable directly:

```
from sound.effects.echo import echofilter
```

Again, this loads the submodule **echo**, but this makes its function **echofilter()** directly available:

```
echofilter(input, output, delay=0.7, atten=4)
```

Note that when using `from package import item`, the item can be either a submodule (or subpackage) of the package, or some other name defined in the package, like a function, class or variable. The `import` statement first tests whether the item is defined in the package; if not, it assumes it is a module and attempts to load it. If it fails to find it, an **ImportError** exception is raised.

Contrarily, when using syntax like `import item.subitem.subsubitem`, each item except for the last must be a package; the last item can be a module or a package but can't be a class or function or variable defined in the previous item.

### 6.4.1. Importing \* From a Package

Now what happens when the user writes `from sound.effects import *`? Ideally, one would hope that this somehow goes out to the filesystem, finds which submodules are present in the package, and imports them all. This could take a long time and importing sub-modules might have unwanted side-effects that should only happen when the sub-module is explicitly imported.

The only solution is for the package author to provide an explicit index of the package. The **import** statement uses the following

convention: if a package's `__init__.py` code defines a list named `__all__`, it is taken to be the list of module names that should be imported when `from package import *` is encountered. It is up to the package author to keep this list up-to-date when a new version of the package is released. Package authors may also decide not to support it, if they don't see a use for importing `*` from their package. For example, the file `sound/effects/__init__.py` could contain the following code:

```
__all__ = ["echo", "surround", "reverse"]
```

This would mean that `from sound.effects import *` would import the three named submodules of the **`sound.effects`** package.

If `__all__` is not defined, the statement `from sound.effects import *` does *not* import all submodules from the package **`sound.effects`** into the current namespace; it only ensures that the package **`sound.effects`** has been imported (possibly running any initialization code in `__init__.py`) and then imports whatever names are defined in the package. This includes any names defined (and submodules explicitly loaded) by `__init__.py`. It also includes any submodules of the package that were explicitly loaded by previous **`import`** statements. Consider this code:

```
import sound.effects.echo
import sound.effects.surround
from sound.effects import *
```

In this example, the **`echo`** and **`surround`** modules are imported in the current namespace because they are defined in the **`sound.effects`** package when the `from...import` statement is executed. (This also works when `__all__` is defined.)

Although certain modules are designed to export only names that follow certain patterns when you use `import *`, it is still considered bad practice in production code.

Remember, there is nothing wrong with using `from package import specific_submodule`! In fact, this is the recommended

notation unless the importing module needs to use submodules with the same name from different packages.

### 6.4.2. Intra-package References

When packages are structured into subpackages (as with the **sound** package in the example), you can use absolute imports to refer to submodules of siblings packages. For example, if the module **sound.filters.vocoder** needs to use the **echo** module in the **sound.effects** package, it can use `from sound.effects`  
`import echo`.

You can also write relative imports, with the `from module`  
`import name` form of import statement. These imports use leading dots to indicate the current and parent packages involved in the relative import. From the **surround** module for example, you might use:

```
from . import echo
from .. import formats
from ..filters import equalizer
```

Note that relative imports are based on the name of the current module. Since the name of the main module is always `"__main__"`, modules intended for use as the main module of a Python application must always use absolute imports.

### 6.4.3. Packages in Multiple Directories

Packages support one more special attribute, `__path__`. This is initialized to be a list containing the name of the directory holding the package's `__init__.py` before the code in that file is executed. This variable can be modified; doing so affects future searches for modules and subpackages contained in the package.

While this feature is not often needed, it can be used to extend the set of modules found in a package.

## Footnotes

In fact function definitions are also ‘statements’ that are ‘executed’; the execution of a module-level function definition adds the function name to the module’s global namespace.

# 7. Input and Output

There are several ways to present the output of a program; data can be printed in a human-readable form, or written to a file for future use. This chapter will discuss some of the possibilities.

## 7.1. Fancier Output Formatting

So far we've encountered two ways of writing values: *expression statements* and the `print()` function. (A third way is using the `write()` method of file objects; the standard output file can be referenced as `sys.stdout`. See the Library Reference for more information on this.)

Often you'll want more control over the formatting of your output than simply printing space-separated values. There are several ways to format output.

- To use [formatted string literals](#), begin a string with `f` or `F` before the opening quotation mark or triple quotation mark. Inside this string, you can write a Python expression between `{` and `}` characters that can refer to variables or literal values.

```
>>> year = 2016
>>> event = 'Referendum'
>>> f'Results of the {year} {event}'
'Results of the 2016 Referendum'
```

- The `str.format()` method of strings requires more manual effort. You'll still use `{` and `}` to mark where a variable will be substituted and can provide detailed formatting directives, but you'll also need to provide the information to be formatted.

```
>>> yes_votes = 42_572_654
```

```
>>> no_votes = 43_132_495
>>> percentage = yes_votes / (yes_votes + no_votes)
>>> '{:-9} YES votes  {:2.2%}'.format(yes_votes, pe
' 42572654 YES votes  49.67%'
```

- Finally, you can do all the string handling yourself by using string slicing and concatenation operations to create any layout you can imagine. The string type has some methods that perform useful operations for padding strings to a given column width.

When you don't need fancy output but just want a quick display of some variables for debugging purposes, you can convert any value to a string with the `repr()` or `str()` functions.

The `str()` function is meant to return representations of values which are fairly human-readable, while `repr()` is meant to generate representations which can be read by the interpreter (or will force a `SyntaxError` if there is no equivalent syntax). For objects which don't have a particular representation for human consumption, `str()` will return the same value as `repr()`. Many values, such as numbers or structures like lists and dictionaries, have the same representation using either function. Strings, in particular, have two distinct representations.

Some examples:

```
>>> s = 'Hello, world.'
>>> str(s)
'Hello, world.'
>>> repr(s)
"'Hello, world.'"
>>> str(1/7)
'0.14285714285714285'
>>> x = 10 * 3.25
>>> y = 200 * 200
>>> s = 'The value of x is ' + repr(x) + ', and y is ' +
>>> print(s)
The value of x is 32.5, and y is 40000...
>>> # The repr() of a string adds string quotes and back
```

```
... hello = 'hello, world\n'
>>> hellos = repr(hello)
>>> print(hellos)
'hello, world\n'
>>> # The argument to repr() may be any Python object:
... repr((x, y, ('spam', 'eggs'))
"(32.5, 40000, ('spam', 'eggs'))"
```

The **string** module contains a **Template** class that offers yet another way to substitute values into strings, using placeholders like `$x` and replacing them with values from a dictionary, but offers much less control of the formatting.

### 7.1.1. Formatted String Literals

**Formatted string literals** (also called f-strings for short) let you include the value of Python expressions inside a string by prefixing the string with `f` or `F` and writing expressions as `{expression}`.

An optional format specifier can follow the expression. This allows greater control over how the value is formatted. The following example rounds pi to three places after the decimal:

```
>>> import math
>>> print(f'The value of pi is approximately {math.pi:.3f}')
The value of pi is approximately 3.142.
```

Passing an integer after the `:` will cause that field to be a minimum number of characters wide. This is useful for making columns line up.

```
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 7678}
>>> for name, phone in table.items():
...     print(f'{name:10} ==> {phone:10d}')
...
Sjoerd      ==>      4127
Jack        ==>      4098
Dcab        ==>      7678
```

Other modifiers can be used to convert the value before it is

formatted. `'!a'` applies `ascii()`, `'!s'` applies `str()`, and `'!r'` applies `repr()`:

```
>>> animals = 'eels'
>>> print(f'My hovercraft is full of {animals}.')
My hovercraft is full of eels.
>>> print(f'My hovercraft is full of {animals!r}.')
My hovercraft is full of 'eels'.
```

The `=` specifier can be used to expand an expression to the text of the expression, an equal sign, then the representation of the evaluated expression:

```
>>> bugs = 'roaches'
>>> count = 13
>>> area = 'living room'
>>> print(f'Debugging {bugs=} {count=} {area=}')
Debugging bugs='roaches' count=13 area='living room'
```

See [self-documenting expressions](#) for more information on the `=` specifier. For a reference on these format specifications, see the reference guide for the [Format Specification Mini-Language](#).

### 7.1.2. The String `format()` Method

Basic usage of the `str.format()` method looks like this:

```
>>> print('We are the {} who say "{}!".format('knights'
We are the knights who say "Ni!"
```

The brackets and characters within them (called format fields) are replaced with the objects passed into the `str.format()` method. A number in the brackets can be used to refer to the position of the object passed into the `str.format()` method.

```
>>> print('{0} and {1}'.format('spam', 'eggs'))
spam and eggs
>>> print('{1} and {0}'.format('spam', 'eggs'))
eggs and spam
```

If keyword arguments are used in the `str.format()` method,

their values are referred to by using the name of the argument.

```
>>> print('This {food} is {adjective}.'.format(
...     food='spam', adjective='absolutely horrible'))
This spam is absolutely horrible.
```

Positional and keyword arguments can be arbitrarily combined:

```
>>> print('The story of {0}, {1}, and {other}.'.format('C', 'Bill', 'Manfred'))
...
The story of Bill, Manfred, and Georg.
```

If you have a really long format string that you don't want to split up, it would be nice if you could reference the variables to be formatted by name instead of by position. This can be done by simply passing the dict and using square brackets '[]' to access the keys.

```
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 8637678}
>>> print('Jack: {0[Jack]:d}; Sjoerd: {0[Sjoerd]:d}; '
...      'Dcab: {0[Dcab]:d}'.format(table))
Jack: 4098; Sjoerd: 4127; Dcab: 8637678
```

This could also be done by passing the `table` dictionary as keyword arguments with the `**` notation.

```
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 8637678}
>>> print('Jack: {Jack:d}; Sjoerd: {Sjoerd:d}; Dcab: {Dcab:d}'.format(**table))
Jack: 4098; Sjoerd: 4127; Dcab: 8637678
```

This is particularly useful in combination with the built-in function `vars()`, which returns a dictionary containing all local variables.

As an example, the following lines produce a tidily aligned set of columns giving integers and their squares and cubes:

```
>>> for x in range(1, 11):
...     print('{0:2d} {1:3d} {2:4d}'.format(x, x*x, x*x*x))
...
1    1    1
2    4    8
```

3	9	27
4	16	64
5	25	125
6	36	216
7	49	343
8	64	512
9	81	729
10	100	1000

For a complete overview of string formatting with `str.format()`, see [Format String Syntax](#).

### 7.1.3. Manual String Formatting

Here's the same table of squares and cubes, formatted manually:

```
>>> for x in range(1, 11):
...     print(repr(x).rjust(2), repr(x*x).rjust(3), end=
...         # Note use of 'end' on previous line
...         print(repr(x*x*x).rjust(4))
...
1    1    1
2    4    8
3    9   27
4   16   64
5   25  125
6   36  216
7   49  343
8   64  512
9   81  729
10 100 1000
```

(Note that the one space between each column was added by the way `print()` works: it always adds spaces between its arguments.)

The `str.rjust()` method of string objects right-justifies a string in a field of a given width by padding it with spaces on the left. There are similar methods `str.ljust()` and `str.center()`. These methods do not write anything, they just return a new string.

If the input string is too long, they don't truncate it, but return it unchanged; this will mess up your column lay-out but that's usually better than the alternative, which would be lying about a value. (If you really want truncation you can always add a slice operation, as in `x.ljust(n)[:n]`.)

There is another method, `str.zfill()`, which pads a numeric string on the left with zeros. It understands about plus and minus signs:

```
>>> '12'.zfill(5)
'00012'
>>> '-3.14'.zfill(7)
'-003.14'
>>> '3.14159265359'.zfill(5)
'3.14159265359'
```

### 7.1.4. Old string formatting

The `%` operator (modulo) can also be used for string formatting. Given `'string' % values`, instances of `%` in `string` are replaced with zero or more elements of `values`. This operation is commonly known as string interpolation. For example:

```
>>> import math
>>> print('The value of pi is approximately %5.3f.' % math.pi)
The value of pi is approximately 3.142.
```

More information can be found in the [printf-style String Formatting](#) section.

## 7.2. Reading and Writing Files

`open()` returns a [file object](#), and is most commonly used with two positional arguments and one keyword argument:

```
open(filename, mode, encoding=None)
```

```
>>> f = open('workfile', 'w', encoding="utf-8")
```

The first argument is a string containing the filename. The second

argument is another string containing a few characters describing the way in which the file will be used. *mode* can be `'r'` when the file will only be read, `'w'` for only writing (an existing file with the same name will be erased), and `'a'` opens the file for appending; any data written to the file is automatically added to the end. `'r+'` opens the file for both reading and writing. The *mode* argument is optional; `'r'` will be assumed if it's omitted.

Normally, files are opened in *text mode*, that means, you read and write strings from and to the file, which are encoded in a specific *encoding*. If *encoding* is not specified, the default is platform dependent (see `open()`). Because UTF-8 is the modern de-facto standard, `encoding="utf-8"` is recommended unless you know that you need to use a different encoding. Appending a `'b'` to the mode opens the file in *binary mode*. Binary mode data is read and written as `bytes` objects. You can not specify *encoding* when opening file in binary mode.

In text mode, the default when reading is to convert platform-specific line endings (`\n` on Unix, `\r\n` on Windows) to just `\n`. When writing in text mode, the default is to convert occurrences of `\n` back to platform-specific line endings. This behind-the-scenes modification to file data is fine for text files, but will corrupt binary data like that in JPEG or EXE files. Be very careful to use binary mode when reading and writing such files.

It is good practice to use the `with` keyword when dealing with file objects. The advantage is that the file is properly closed after its suite finishes, even if an exception is raised at some point. Using `with` is also much shorter than writing equivalent `try-finally` blocks:

```
>>> with open('workfile', encoding="utf-8") as f:
...     read_data = f.read()

>>> # We can check that the file has been automatically
>>> f.closed
True
```

If you're not using the `with` keyword, then you should call `f.close()` to close the file and immediately free up any system

resources used by it.

## Warning

Calling `f.write()` without using the **with** keyword or calling `f.close()` **might** result in the arguments of `f.write()` not being completely written to the disk, even if the program exits successfully.

After a file object is closed, either by a **with** statement or by calling `f.close()`, attempts to use the file object will automatically fail.

```
>>> f.close()
>>> f.read()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: I/O operation on closed file.
```

### 7.2.1. Methods of File Objects

The rest of the examples in this section will assume that a file object called `f` has already been created.

To read a file's contents, call `f.read(size)`, which reads some quantity of data and returns it as a string (in text mode) or bytes object (in binary mode). *size* is an optional numeric argument. When *size* is omitted or negative, the entire contents of the file will be read and returned; it's your problem if the file is twice as large as your machine's memory. Otherwise, at most *size* characters (in text mode) or *size* bytes (in binary mode) are read and returned. If the end of the file has been reached, `f.read()` will return an empty string ('').

```
>>> f.read()
'This is the entire file.\n'
>>> f.read()
''
```

`f.readline()` reads a single line from the file; a newline

character (`\n`) is left at the end of the string, and is only omitted on the last line of the file if the file doesn't end in a newline. This makes the return value unambiguous; if `f.readline()` returns an empty string, the end of the file has been reached, while a blank line is represented by `'\n'`, a string containing only a single newline.

```
>>> f.readline()
'This is the first line of the file.\n'
>>> f.readline()
'Second line of the file\n'
>>> f.readline()
''
```

For reading lines from a file, you can loop over the file object. This is memory efficient, fast, and leads to simple code:

```
>>> for line in f:
...     print(line, end='')
...
This is the first line of the file.
Second line of the file
```

If you want to read all the lines of a file in a list you can also use `list(f)` or `f.readlines()`.

`f.write(string)` writes the contents of *string* to the file, returning the number of characters written.

```
>>> f.write('This is a test\n')
15
```

Other types of objects need to be converted – either to a string (in text mode) or a bytes object (in binary mode) – before writing them:

```
>>> value = ('the answer', 42)
>>> s = str(value) # convert the tuple to string
>>> f.write(s)
18
```

`f.tell()` returns an integer giving the file object's current position in the file represented as number of bytes from the beginning of the file when in binary mode and an opaque number when in text mode.

To change the file object's position, use `f.seek(offset, whence)`. The position is computed from adding *offset* to a reference point; the reference point is selected by the *whence* argument. A *whence* value of 0 measures from the beginning of the file, 1 uses the current file position, and 2 uses the end of the file as the reference point. *whence* can be omitted and defaults to 0, using the beginning of the file as the reference point.

```
>>> f = open('workfile', 'rb+')
>>> f.write(b'0123456789abcdef')
16
>>> f.seek(5)          # Go to the 6th byte in the file
5
>>> f.read(1)
b'5'
>>> f.seek(-3, 2)      # Go to the 3rd byte before the end
13
>>> f.read(1)
b'd'
```

In text files (those opened without a `b` in the mode string), only seeks relative to the beginning of the file are allowed (the exception being seeking to the very file end with `seek(0, 2)`) and the only valid *offset* values are those returned from the `f.tell()`, or zero. Any other *offset* value produces undefined behaviour.

File objects have some additional methods, such as `isatty()` and `truncate()` which are less frequently used; consult the Library Reference for a complete guide to file objects.

### 7.2.2. Saving structured data with `json`

Strings can easily be written to and read from a file. Numbers take a bit more effort, since the `read()` method only returns strings, which will have to be passed to a function like `int()`, which takes

a string like `'123'` and returns its numeric value 123. When you want to save more complex data types like nested lists and dictionaries, parsing and serializing by hand becomes complicated.

Rather than having users constantly writing and debugging code to save complicated data types to files, Python allows you to use the popular data interchange format called [JSON \(JavaScript Object Notation\)](https://json.org) [https://json.org]. The standard module called `json` can take Python data hierarchies, and convert them to string representations; this process is called *serializing*. Reconstructing the data from the string representation is called *deserializing*. Between serializing and deserializing, the string representing the object may have been stored in a file or data, or sent over a network connection to some distant machine.

## Note

The JSON format is commonly used by modern applications to allow for data exchange. Many programmers are already familiar with it, which makes it a good choice for interoperability.

If you have an object `x`, you can view its JSON string representation with a simple line of code:

```
>>> import json
>>> x = [1, 'simple', 'list']
>>> json.dumps(x)
'[1, "simple", "list"]'
```

Another variant of the `dumps()` function, called `dump()`, simply serializes the object to a [text file](#). So if `f` is a [text file](#) object opened for writing, we can do this:

```
json.dump(x, f)
```

To decode the object again, if `f` is a [binary file](#) or [text file](#) object which has been opened for reading:

```
x = json.load(f)
```

## Note

JSON files must be encoded in UTF-8. Use `encoding="utf-8"` when opening JSON file as a [text file](#) for both of reading and writing.

This simple serialization technique can handle lists and dictionaries, but serializing arbitrary class instances in JSON requires a bit of extra effort. The reference for the [json](#) module contains an explanation of this.

## See also

[pickle](#) - the pickle module

Contrary to [JSON](#), *pickle* is a protocol which allows the serialization of arbitrarily complex Python objects. As such, it is specific to Python and cannot be used to communicate with applications written in other languages. It is also insecure by default: deserializing pickle data coming from an untrusted source can execute arbitrary code, if the data was crafted by a skilled attacker.

## 8. Errors and Exceptions

Until now error messages haven't been more than mentioned, but if you have tried out the examples you have probably seen some. There are (at least) two distinguishable kinds of errors: *syntax errors* and *exceptions*.

### 8.1. Syntax Errors

Syntax errors, also known as parsing errors, are perhaps the most common kind of complaint you get while you are still learning Python:

```
>>> while True print('Hello world')
      File "<stdin>", line 1
        while True print('Hello world')
                        ^
SyntaxError: invalid syntax
```

The parser repeats the offending line and displays a little ‘arrow’ pointing at the earliest point in the line where the error was detected. The error is caused by (or at least detected at) the token *preceding* the arrow: in the example, the error is detected at the function `print()`, since a colon (':') is missing before it. File name and line number are printed so you know where to look in case the input came from a script.

### 8.2. Exceptions

Even if a statement or expression is syntactically correct, it may cause an error when an attempt is made to execute it. Errors detected during execution are called *exceptions* and are not unconditionally fatal: you will soon learn how to handle them in Python programs. Most exceptions are not handled by programs, however, and result in error messages as shown here:

```
>>> 10 * (1/0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ZeroDivisionError: division by zero
>>> 4 + spam*3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'spam' is not defined
>>> '2' + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: can only concatenate str (not "int") to str
```

The last line of the error message indicates what happened. Exceptions come in different types, and the type is printed as part of the message: the types in the example are **ZeroDivisionError**, **NameError** and **TypeError**. The string printed as the exception type is the name of the built-in exception that occurred. This is true for all built-in exceptions, but need not be true for user-defined exceptions (although it is a useful convention). Standard exception names are built-in identifiers (not reserved keywords).

The rest of the line provides detail based on the type of exception and what caused it.

The preceding part of the error message shows the context where the exception occurred, in the form of a stack traceback. In general it contains a stack traceback listing source lines; however, it will not display lines read from standard input.

**Built-in Exceptions** lists the built-in exceptions and their meanings.

## 8.3. Handling Exceptions

It is possible to write programs that handle selected exceptions. Look at the following example, which asks the user for input until a valid integer has been entered, but allows the user to interrupt the program (using **Control-C** or whatever the operating system supports); note that a user-generated interruption is signalled by raising the **KeyboardInterrupt** exception.

```
>>> while True:
...     try:
...         x = int(input("Please enter a number: "))
...         break
...     except ValueError:
...         print("Oops! That was no valid number. Try")
... 
```

The **try** statement works as follows.

- First, the *try clause* (the statement(s) between the **try** and **except** keywords) is executed.
- If no exception occurs, the *except clause* is skipped and execution of the **try** statement is finished.
- If an exception occurs during execution of the **try** clause, the rest of the clause is skipped. Then, if its type matches the exception named after the **except** keyword, the *except clause* is executed, and then execution continues after the try/except block.
- If an exception occurs which does not match the exception named in the *except clause*, it is passed on to outer **try** statements; if no handler is found, it is an *unhandled exception* and execution stops with a message as shown above.

A **try** statement may have more than one *except clause*, to specify handlers for different exceptions. At most one handler will be executed. Handlers only handle exceptions that occur in the corresponding *try clause*, not in other handlers of the same **try** statement. An *except clause* may name multiple exceptions as a parenthesized tuple, for example:

```
... except (RuntimeError, TypeError, NameError):
...     pass
```

A class in an **except** clause is compatible with an exception if it is the same class or a base class thereof (but not the other way around — an *except clause* listing a derived class is not compatible with a base class). For example, the following code will print B, C, D in that order:

```
class B(Exception):
```

```

    pass

class C(B):
    pass

class D(C):
    pass

for cls in [B, C, D]:
    try:
        raise cls()
    except D:
        print("D")
    except C:
        print("C")
    except B:
        print("B")

```

Note that if the *except clauses* were reversed (with `except B` first), it would have printed B, B, B — the first matching *except clause* is triggered.

When an exception occurs, it may have associated values, also known as the exception's *arguments*. The presence and types of the arguments depend on the exception type.

The *except clause* may specify a variable after the exception name. The variable is bound to the exception instance which typically has an `args` attribute that stores the arguments. For convenience, builtin exception types define `__str__()` to print all the arguments without explicitly accessing `.args`.

```

>>> try:
...     raise Exception('spam', 'eggs')
... except Exception as inst:
...     print(type(inst))      # the exception type
...     print(inst.args)      # arguments stored in .args
...     print(inst)           # __str__ allows args to be
...                           # but may be overridden in
...     x, y = inst.args      # unpack args

```

```

...     print('x =', x)
...     print('y =', y)
...
<class 'Exception'>
('spam', 'eggs')
('spam', 'eggs')
x = spam
y = eggs

```

The exception's `__str__()` output is printed as the last part ('detail') of the message for unhandled exceptions.

**BaseException** is the common base class of all exceptions. One of its subclasses, **Exception**, is the base class of all the non-fatal exceptions. Exceptions which are not subclasses of **Exception** are not typically handled, because they are used to indicate that the program should terminate. They include **SystemExit** which is raised by `sys.exit()` and **KeyboardInterrupt** which is raised when a user wishes to interrupt the program.

**Exception** can be used as a wildcard that catches (almost) everything. However, it is good practice to be as specific as possible with the types of exceptions that we intend to handle, and to allow any unexpected exceptions to propagate on.

The most common pattern for handling **Exception** is to print or log the exception and then re-raise it (allowing a caller to handle the exception as well):

```

import sys

try:
    f = open('myfile.txt')
    s = f.readline()
    i = int(s.strip())
except OSError as err:
    print("OS error:", err)
except ValueError:
    print("Could not convert data to an integer.")
except Exception as err:

```

```
print(f"Unexpected {err=}, {type(err)=}")
raise
```

The **try** ... **except** statement has an optional *else clause*, which, when present, must follow all *except clauses*. It is useful for code that must be executed if the *try clause* does not raise an exception. For example:

```
for arg in sys.argv[1:]:
    try:
        f = open(arg, 'r')
    except OSError:
        print('cannot open', arg)
    else:
        print(arg, 'has', len(f.readlines()), 'lines')
        f.close()
```

The use of the **else** clause is better than adding additional code to the **try** clause because it avoids accidentally catching an exception that wasn't raised by the code being protected by the **try** ... **except** statement.

Exception handlers do not handle only exceptions that occur immediately in the *try clause*, but also those that occur inside functions that are called (even indirectly) in the *try clause*. For example:

```
>>> def this_fails():
...     x = 1/0
...
>>> try:
...     this_fails()
... except ZeroDivisionError as err:
...     print('Handling run-time error:', err)
...
Handling run-time error: division by zero
```

## 8.4. Raising Exceptions

The **raise** statement allows the programmer to force a specified exception to occur. For example:

```
>>> raise NameError('HiThere')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: HiThere
```

The sole argument to **raise** indicates the exception to be raised. This must be either an exception instance or an exception class (a class that derives from **BaseException**, such as **Exception** or one of its subclasses). If an exception class is passed, it will be implicitly instantiated by calling its constructor with no arguments:

```
raise ValueError # shorthand for 'raise ValueError()'
```

If you need to determine whether an exception was raised but don't intend to handle it, a simpler form of the **raise** statement allows you to re-raise the exception:

```
>>> try:
...     raise NameError('HiThere')
... except NameError:
...     print('An exception flew by!')
...     raise
...
An exception flew by!
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
NameError: HiThere
```

## 8.5. Exception Chaining

If an unhandled exception occurs inside an **except** section, it will have the exception being handled attached to it and included in the error message:

```
>>> try:
...     open("database.sqlite")
... except OSError:
```

```
...     raise RuntimeError("unable to handle error")
...
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
FileNotFoundError: [Errno 2] No such file or directory:
```

During handling of the above exception, another exception occurred

```
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError: unable to handle error
```

To indicate that an exception is a direct consequence of another, the **raise** statement allows an optional **from** clause:

```
# exc must be exception instance or None.
raise RuntimeError from exc
```

This can be useful when you are transforming exceptions. For example:

```
>>> def func():
...     raise ConnectionError
...
>>> try:
...     func()
... except ConnectionError as exc:
...     raise RuntimeError('Failed to open database') from exc
...
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
  File "<stdin>", line 2, in func
ConnectionError
```

The above exception was the direct cause of the following

```
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError: Failed to open database
```

It also allows disabling automatic exception chaining using the `from None` idiom:

```
>>> try:
...     open('database.sqlite')
... except OSError:
...     raise RuntimeError from None
...
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError
```

For more information about chaining mechanics, see [Built-in Exceptions](#).

## 8.6. User-defined Exceptions

Programs may name their own exceptions by creating a new exception class (see [Classes](#) for more about Python classes). Exceptions should typically be derived from the [Exception](#) class, either directly or indirectly.

Exception classes can be defined which do anything any other class can do, but are usually kept simple, often only offering a number of attributes that allow information about the error to be extracted by handlers for the exception.

Most exceptions are defined with names that end in “Error”, similar to the naming of the standard exceptions.

Many standard modules define their own exceptions to report errors that may occur in functions they define.

## 8.7. Defining Clean-up Actions

The [try](#) statement has another optional clause which is intended to define clean-up actions that must be executed under all circumstances. For example:

```
>>> try:
...     raise KeyboardInterrupt
... finally:
...     print('Goodbye, world!')
...
Goodbye, world!
KeyboardInterrupt
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
```

If a **finally** clause is present, the **finally** clause will execute as the last task before the **try** statement completes. The **finally** clause runs whether or not the **try** statement produces an exception. The following points discuss more complex cases when an exception occurs:

- If an exception occurs during execution of the **try** clause, the exception may be handled by an **except** clause. If the exception is not handled by an **except** clause, the exception is re-raised after the **finally** clause has been executed.
- An exception could occur during execution of an **except** or **else** clause. Again, the exception is re-raised after the **finally** clause has been executed.
- If the **finally** clause executes a **break**, **continue** or **return** statement, exceptions are not re-raised.
- If the **try** statement reaches a **break**, **continue** or **return** statement, the **finally** clause will execute just prior to the **break**, **continue** or **return** statement's execution.
- If a **finally** clause includes a **return** statement, the returned value will be the one from the **finally** clause's **return** statement, not the value from the **try** clause's **return** statement.

For example:

```
>>> def bool_return():
...     try:
...         return True
...     finally:
```

```
...         return False
...
>>> bool_return()
False
```

A more complicated example:

```
>>> def divide(x, y):
...     try:
...         result = x / y
...     except ZeroDivisionError:
...         print("division by zero!")
...     else:
...         print("result is", result)
...     finally:
...         print("executing finally clause")
...
>>> divide(2, 1)
result is 2.0
executing finally clause
>>> divide(2, 0)
division by zero!
executing finally clause
>>> divide("2", "1")
executing finally clause
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in divide
TypeError: unsupported operand type(s) for /: 'str' and
```

As you can see, the **finally** clause is executed in any event. The **TypeError** raised by dividing two strings is not handled by the **except** clause and therefore re-raised after the **finally** clause has been executed.

In real world applications, the **finally** clause is useful for releasing external resources (such as files or network connections), regardless of whether the use of the resource was successful.

## 8.8. Predefined Clean-up Actions

Some objects define standard clean-up actions to be undertaken when the object is no longer needed, regardless of whether or not the operation using the object succeeded or failed. Look at the following example, which tries to open a file and print its contents to the screen.

```
for line in open("myfile.txt"):  
    print(line, end="")
```

The problem with this code is that it leaves the file open for an indeterminate amount of time after this part of the code has finished executing. This is not an issue in simple scripts, but can be a problem for larger applications. The `with` statement allows objects like files to be used in a way that ensures they are always cleaned up promptly and correctly.

```
with open("myfile.txt") as f:  
    for line in f:  
        print(line, end="")
```

After the statement is executed, the file *f* is always closed, even if a problem was encountered while processing the lines. Objects which, like files, provide predefined clean-up actions will indicate this in their documentation.

## 8.9. Raising and Handling Multiple Unrelated Exceptions

There are situations where it is necessary to report several exceptions that have occurred. This is often the case in concurrency frameworks, when several tasks may have failed in parallel, but there are also other use cases where it is desirable to continue execution and collect multiple errors rather than raise the first exception.

The builtin `ExceptionGroup` wraps a list of exception instances so that they can be raised together. It is an exception itself, so it can

be caught like any other exception.

```
>>> def f():
...     excs = [OSError('error 1'), SystemError('error 2')]
...     raise ExceptionGroup('there were problems', excs)
...
>>> f()
+ Exception Group Traceback (most recent call last):
|   File "<stdin>", line 1, in <module>
|   File "<stdin>", line 3, in f
| ExceptionGroup: there were problems
+----- 1 -----
|   OSError: error 1
+----- 2 -----
|   SystemError: error 2
+-----
>>> try:
...     f()
... except Exception as e:
...     print(f'caught {type(e)}: e')
...
caught <class 'ExceptionGroup': e
>>>
```

By using `except*` instead of `except`, we can selectively handle only the exceptions in the group that match a certain type. In the following example, which shows a nested exception group, each `except*` clause extracts from the group exceptions of a certain type while letting all other exceptions propagate to other clauses and eventually to be reraised.

```
>>> def f():
...     raise ExceptionGroup("group1",
...                           [OSError(1),
...                             SystemError(2),
...                             ExceptionGroup("group2",
...                                             [OSError(3)
...                                             ]
...                                             )
...                           ]
... )
>>> try:
```

```

...     f()
... except* OSError as e:
...     print("There were OSErrors")
... except* SystemError as e:
...     print("There were SystemErrors")
...
There were OSErrors
There were SystemErrors
+ Exception Group Traceback (most recent call last):
|   File "<stdin>", line 2, in <module>
|   File "<stdin>", line 2, in f
| ExceptionGroup: group1
+-+----- 1 -----
| ExceptionGroup: group2
+-+----- 1 -----
| RecursionError: 4
+-----
>>>

```

Note that the exceptions nested in an exception group must be instances, not types. This is because in practice the exceptions would typically be ones that have already been raised and caught by the program, along the following pattern:

```

>>> excs = []
... for test in tests:
...     try:
...         test.run()
...     except Exception as e:
...         excs.append(e)
...
>>> if excs:
...     raise ExceptionGroup("Test Failures", excs)
...

```

## 8.10. Enriching Exceptions with Notes

When an exception is created in order to be raised, it is usually initialized with information that describes the error that has

occurred. There are cases where it is useful to add information after the exception was caught. For this purpose, exceptions have a method `add_note(note)` that accepts a string and adds it to the exception's notes list. The standard traceback rendering includes all notes, in the order they were added, after the exception.

```
>>> try:
...     raise TypeError('bad type')
... except Exception as e:
...     e.add_note('Add some information')
...     e.add_note('Add some more information')
...     raise
...
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
TypeError: bad type
Add some information
Add some more information
>>>
```

For example, when collecting exceptions into an exception group, we may want to add context information for the individual errors. In the following each exception in the group has a note indicating when this error has occurred.

```
>>> def f():
...     raise OSError('operation failed')
...
>>> excs = []
>>> for i in range(3):
...     try:
...         f()
...     except Exception as e:
...         e.add_note(f'Happened in Iteration {i+1}')
...         excs.append(e)
...
>>> raise ExceptionGroup('We have some problems', excs)
+ Exception Group Traceback (most recent call last):
|   File "<stdin>", line 1, in <module>
```

| ExceptionGroup: We have some problems (3 sub-exceptions)

+----- 1 -----

| Traceback (most recent call last):  
| File "<stdin>", line 3, in <module>  
| File "<stdin>", line 2, in f  
| OSError: operation failed  
| Happened in Iteration 1

+----- 2 -----

| Traceback (most recent call last):  
| File "<stdin>", line 3, in <module>  
| File "<stdin>", line 2, in f  
| OSError: operation failed  
| Happened in Iteration 2

+----- 3 -----

| Traceback (most recent call last):  
| File "<stdin>", line 3, in <module>  
| File "<stdin>", line 2, in f  
| OSError: operation failed  
| Happened in Iteration 3

+-----

>>>

## 9. Classes

Classes provide a means of bundling data and functionality together. Creating a new class creates a new *type* of object, allowing new *instances* of that type to be made. Each class instance can have attributes attached to it for maintaining its state. Class instances can also have methods (defined by its class) for modifying its state.

Compared with other programming languages, Python's class mechanism adds classes with a minimum of new syntax and semantics. It is a mixture of the class mechanisms found in C++ and Modula-3. Python classes provide all the standard features of Object Oriented Programming: the class inheritance mechanism allows multiple base classes, a derived class can override any methods of its base class or classes, and a method can call the method of a base class with the same name. Objects can contain arbitrary amounts and kinds of data. As is true for modules, classes partake of the dynamic nature of Python: they are created at runtime, and can be modified further after creation.

In C++ terminology, normally class members (including the data members) are *public* (except see below [Private Variables](#)), and all member functions are *virtual*. As in Modula-3, there are no shorthands for referencing the object's members from its methods: the method function is declared with an explicit first argument representing the object, which is provided implicitly by the call. As in Smalltalk, classes themselves are objects. This provides semantics for importing and renaming. Unlike C++ and Modula-3, built-in types can be used as base classes for extension by the user. Also, like in C++, most built-in operators with special syntax (arithmetic operators, subscripting etc.) can be redefined for class instances.

(Lacking universally accepted terminology to talk about classes, I will make occasional use of Smalltalk and C++ terms. I would use Modula-3 terms, since its object-oriented semantics are closer to

those of Python than C++ , but I expect that few readers have heard of it.)

## 9.1. A Word About Names and Objects

Objects have individuality, and multiple names (in multiple scopes) can be bound to the same object. This is known as aliasing in other languages. This is usually not appreciated on a first glance at Python, and can be safely ignored when dealing with immutable basic types (numbers, strings, tuples). However, aliasing has a possibly surprising effect on the semantics of Python code involving mutable objects such as lists, dictionaries, and most other types. This is usually used to the benefit of the program, since aliases behave like pointers in some respects. For example, passing an object is cheap since only a pointer is passed by the implementation; and if a function modifies an object passed as an argument, the caller will see the change — this eliminates the need for two different argument passing mechanisms as in Pascal.

## 9.2. Python Scopes and Namespaces

Before introducing classes, I first have to tell you something about Python's scope rules. Class definitions play some neat tricks with namespaces, and you need to know how scopes and namespaces work to fully understand what's going on. Incidentally, knowledge about this subject is useful for any advanced Python programmer.

Let's begin with some definitions.

A *namespace* is a mapping from names to objects. Most namespaces are currently implemented as Python dictionaries, but that's normally not noticeable in any way (except for performance), and it may change in the future. Examples of namespaces are: the set of built-in names (containing functions such as `abs()`, and built-in exception names); the global names in a module; and the local names in a function invocation. In a sense the set of attributes of an object also form a namespace. The important thing to know about namespaces is that there is absolutely no relation between names in different namespaces; for instance, two different modules may both

define a function `maximize` without confusion — users of the modules must prefix it with the module name.

By the way, I use the word *attribute* for any name following a dot — for example, in the expression `z.real`, `real` is an attribute of the object `z`. Strictly speaking, references to names in modules are attribute references: in the expression `modname.funcname`, `modname` is a module object and `funcname` is an attribute of it. In this case there happens to be a straightforward mapping between the module's attributes and the global names defined in the module: they share the same namespace! <sup>1</sup>

Attributes may be read-only or writable. In the latter case, assignment to attributes is possible. Module attributes are writable: you can write `modname.the_answer = 42`. Writable attributes may also be deleted with the `del` statement. For example, `del modname.the_answer` will remove the attribute `the_answer` from the object named by `modname`.

Namespaces are created at different moments and have different lifetimes. The namespace containing the built-in names is created when the Python interpreter starts up, and is never deleted. The global namespace for a module is created when the module definition is read in; normally, module namespaces also last until the interpreter quits. The statements executed by the top-level invocation of the interpreter, either read from a script file or interactively, are considered part of a module called `__main__`, so they have their own global namespace. (The built-in names actually also live in a module; this is called `builtins`.)

The local namespace for a function is created when the function is called, and deleted when the function returns or raises an exception that is not handled within the function. (Actually, forgetting would be a better way to describe what actually happens.) Of course, recursive invocations each have their own local namespace.

A *scope* is a textual region of a Python program where a namespace is directly accessible. “Directly accessible” here means that an unqualified reference to a name attempts to find the name in the namespace.

Although scopes are determined statically, they are used dynamically. At any time during execution, there are 3 or 4 nested scopes whose namespaces are directly accessible:

- the innermost scope, which is searched first, contains the local names
- the scopes of any enclosing functions, which are searched starting with the nearest enclosing scope, contain non-local, but also non-global names
- the next-to-last scope contains the current module's global names
- the outermost scope (searched last) is the namespace containing built-in names

If a name is declared global, then all references and assignments go directly to the next-to-last scope containing the module's global names. To rebind variables found outside of the innermost scope, the `nonlocal` statement can be used; if not declared nonlocal, those variables are read-only (an attempt to write to such a variable will simply create a *new* local variable in the innermost scope, leaving the identically named outer variable unchanged).

Usually, the local scope references the local names of the (textually) current function. Outside functions, the local scope references the same namespace as the global scope: the module's namespace. Class definitions place yet another namespace in the local scope.

It is important to realize that scopes are determined textually: the global scope of a function defined in a module is that module's namespace, no matter from where or by what alias the function is called. On the other hand, the actual search for names is done dynamically, at run time — however, the language definition is evolving towards static name resolution, at “compile” time, so don't rely on dynamic name resolution! (In fact, local variables are already determined statically.)

A special quirk of Python is that – if no `global` or `nonlocal` statement is in effect – assignments to names always go into the innermost scope. Assignments do not copy data — they just bind names to objects. The same is true for deletions: the statement `del x` removes the binding of `x` from the namespace referenced by the

local scope. In fact, all operations that introduce new names use the local scope: in particular, `import` statements and function definitions bind the module or function name in the local scope.

The `global` statement can be used to indicate that particular variables live in the global scope and should be rebound there; the `nonlocal` statement indicates that particular variables live in an enclosing scope and should be rebound there.

### 9.2.1. Scopes and Namespaces Example

This is an example demonstrating how to reference the different scopes and namespaces, and how `global` and `nonlocal` affect variable binding:

```
def scope_test():
    def do_local():
        spam = "local spam"

    def do_nonlocal():
        nonlocal spam
        spam = "nonlocal spam"

    def do_global():
        global spam
        spam = "global spam"

    spam = "test spam"
    do_local()
    print("After local assignment:", spam)
    do_nonlocal()
    print("After nonlocal assignment:", spam)
    do_global()
    print("After global assignment:", spam)

scope_test()
print("In global scope:", spam)
```

The output of the example code is:

```
After local assignment: test spam
After nonlocal assignment: nonlocal spam
After global assignment: nonlocal spam
In global scope: global spam
```

Note how the *local* assignment (which is default) didn't change *scope\_test*'s binding of *spam*. The **nonlocal** assignment changed *scope\_test*'s binding of *spam*, and the **global** assignment changed the module-level binding.

You can also see that there was no previous binding for *spam* before the **global** assignment.

## 9.3. A First Look at Classes

Classes introduce a little bit of new syntax, three new object types, and some new semantics.

### 9.3.1. Class Definition Syntax

The simplest form of class definition looks like this:

```
class ClassName:
    <statement-1>
    .
    .
    .
    <statement-N>
```

Class definitions, like function definitions (**def** statements) must be executed before they have any effect. (You could conceivably place a class definition in a branch of an **if** statement, or inside a function.)

In practice, the statements inside a class definition will usually be function definitions, but other statements are allowed, and sometimes useful — we'll come back to this later. The function definitions inside a class normally have a peculiar form of argument list, dictated by the calling conventions for methods — again, this is explained later.

When a class definition is entered, a new namespace is created, and used as the local scope — thus, all assignments to local variables go into this new namespace. In particular, function definitions bind the name of the new function here.

When a class definition is left normally (via the end), a *class object* is created. This is basically a wrapper around the contents of the namespace created by the class definition; we'll learn more about class objects in the next section. The original local scope (the one in effect just before the class definition was entered) is reinstated, and the class object is bound here to the class name given in the class definition header (**ClassName** in the example).

### 9.3.2. Class Objects

Class objects support two kinds of operations: attribute references and instantiation.

*Attribute references* use the standard syntax used for all attribute references in Python: `obj.name`. Valid attribute names are all the names that were in the class's namespace when the class object was created. So, if the class definition looked like this:

```
class MyClass:
    """A simple example class"""
    i = 12345

    def f(self):
        return 'hello world'
```

then `MyClass.i` and `MyClass.f` are valid attribute references, returning an integer and a function object, respectively. Class attributes can also be assigned to, so you can change the value of `MyClass.i` by assignment. `__doc__` is also a valid attribute, returning the docstring belonging to the class: "A simple example class".

Class *instantiation* uses function notation. Just pretend that the class object is a parameterless function that returns a new instance of the class. For example (assuming the above class):

```
x = MyClass()
```

creates a new *instance* of the class and assigns this object to the local variable `x`.

The instantiation operation (“calling” a class object) creates an empty object. Many classes like to create objects with instances customized to a specific initial state. Therefore a class may define a special method named `__init__()`, like this:

```
def __init__(self):  
    self.data = []
```

When a class defines an `__init__()` method, class instantiation automatically invokes `__init__()` for the newly created class instance. So in this example, a new, initialized instance can be obtained by:

```
x = MyClass()
```

Of course, the `__init__()` method may have arguments for greater flexibility. In that case, arguments given to the class instantiation operator are passed on to `__init__()`. For example,

```
>>> class Complex:  
...     def __init__(self, realpart, imagpart):  
...         self.r = realpart  
...         self.i = imagpart  
...  
>>> x = Complex(3.0, -4.5)  
>>> x.r, x.i  
(3.0, -4.5)
```

### 9.3.3. Instance Objects

Now what can we do with instance objects? The only operations understood by instance objects are attribute references. There are two kinds of valid attribute names: data attributes and methods.

*data attributes* correspond to “instance variables” in Smalltalk, and to “data members” in C++. Data attributes need not be declared;

like local variables, they spring into existence when they are first assigned to. For example, if `x` is the instance of **MyClass** created above, the following piece of code will print the value `16`, without leaving a trace:

```
x.counter = 1
while x.counter < 10:
    x.counter = x.counter * 2
print(x.counter)
del x.counter
```

The other kind of instance attribute reference is a *method*. A method is a function that “belongs to” an object. (In Python, the term method is not unique to class instances: other object types can have methods as well. For example, list objects have methods called `append`, `insert`, `remove`, `sort`, and so on. However, in the following discussion, we’ll use the term method exclusively to mean methods of class instance objects, unless explicitly stated otherwise.)

Valid method names of an instance object depend on its class. By definition, all attributes of a class that are function objects define corresponding methods of its instances. So in our example, `x.f` is a valid method reference, since `MyClass.f` is a function, but `x.i` is not, since `MyClass.i` is not. But `x.f` is not the same thing as `MyClass.f` — it is a *method object*, not a function object.

### 9.3.4. Method Objects

Usually, a method is called right after it is bound:

```
x.f()
```

In the **MyClass** example, this will return the string `'hello world'`. However, it is not necessary to call a method right away: `x.f` is a method object, and can be stored away and called at a later time. For example:

```
xf = x.f
while True:
    print(xf())
```

will continue to print `hello world` until the end of time.

What exactly happens when a method is called? You may have noticed that `x.f()` was called without an argument above, even though the function definition for `f()` specified an argument. What happened to the argument? Surely Python raises an exception when a function that requires an argument is called without any — even if the argument isn't actually used...

Actually, you may have guessed the answer: the special thing about methods is that the instance object is passed as the first argument of the function. In our example, the call `x.f()` is exactly equivalent to `MyClass.f(x)`. In general, calling a method with a list of  $n$  arguments is equivalent to calling the corresponding function with an argument list that is created by inserting the method's instance object before the first argument.

If you still don't understand how methods work, a look at the implementation can perhaps clarify matters. When a non-data attribute of an instance is referenced, the instance's class is searched. If the name denotes a valid class attribute that is a function object, a method object is created by packing (pointers to) the instance object and the function object just found together in an abstract object: this is the method object. When the method object is called with an argument list, a new argument list is constructed from the instance object and the argument list, and the function object is called with this new argument list.

### 9.3.5. Class and Instance Variables

Generally speaking, instance variables are for data unique to each instance and class variables are for attributes and methods shared by all instances of the class:

```
class Dog:
```

```
    kind = 'canine'           # class variable shared by all
```

```
    def __init__(self, name):
```

```
        self.name = name     # instance variable unique to
```

```

>>> d = Dog('Fido')
>>> e = Dog('Buddy')
>>> d.kind                                # shared by all dogs
'canine'
>>> e.kind                                # shared by all dogs
'canine'
>>> d.name                                # unique to d
'Fido'
>>> e.name                                # unique to e
'Buddy'

```

As discussed in [A Word About Names and Objects](#), shared data can have possibly surprising effects with involving [mutable](#) objects such as lists and dictionaries. For example, the *tricks* list in the following code should not be used as a class variable because just a single list would be shared by all *Dog* instances:

```

class Dog:

    tricks = []                                 # mistaken use of a class variable

    def __init__(self, name):
        self.name = name

    def add_trick(self, trick):
        self.tricks.append(trick)

>>> d = Dog('Fido')
>>> e = Dog('Buddy')
>>> d.add_trick('roll over')
>>> e.add_trick('play dead')
>>> d.tricks                                # unexpectedly shared by all
['roll over', 'play dead']

```

Correct design of the class should use an instance variable instead:

```

class Dog:

```

```

def __init__(self, name):
    self.name = name
    self.tricks = []      # creates a new empty list f

def add_trick(self, trick):
    self.tricks.append(trick)

>>> d = Dog('Fido')
>>> e = Dog('Buddy')
>>> d.add_trick('roll over')
>>> e.add_trick('play dead')
>>> d.tricks
['roll over']
>>> e.tricks
['play dead']

```

## 9.4. Random Remarks

If the same attribute name occurs in both an instance and in a class, then attribute lookup prioritizes the instance:

```

>>> class Warehouse:
...     purpose = 'storage'
...     region = 'west'
...
>>> w1 = Warehouse()
>>> print(w1.purpose, w1.region)
storage west
>>> w2 = Warehouse()
>>> w2.region = 'east'
>>> print(w2.purpose, w2.region)
storage east

```

Data attributes may be referenced by methods as well as by ordinary users (“clients”) of an object. In other words, classes are not usable to implement pure abstract data types. In fact, nothing in Python makes it possible to enforce data hiding — it is all based upon convention. (On the other hand, the Python implementation, written in C, can completely hide implementation details and

control access to an object if necessary; this can be used by extensions to Python written in C.)

Clients should use data attributes with care — clients may mess up invariants maintained by the methods by stamping on their data attributes. Note that clients may add data attributes of their own to an instance object without affecting the validity of the methods, as long as name conflicts are avoided — again, a naming convention can save a lot of headaches here.

There is no shorthand for referencing data attributes (or other methods!) from within methods. I find that this actually increases the readability of methods: there is no chance of confusing local variables and instance variables when glancing through a method.

Often, the first argument of a method is called `self`. This is nothing more than a convention: the name `self` has absolutely no special meaning to Python. Note, however, that by not following the convention your code may be less readable to other Python programmers, and it is also conceivable that a *class browser* program might be written that relies upon such a convention.

Any function object that is a class attribute defines a method for instances of that class. It is not necessary that the function definition is textually enclosed in the class definition: assigning a function object to a local variable in the class is also ok. For example:

```
# Function defined outside the class
def f1(self, x, y):
    return min(x, x+y)

class C:
    f = f1

    def g(self):
        return 'hello world'

    h = g
```

Now `f`, `g` and `h` are all attributes of class `C` that refer to function objects, and consequently they are all methods of instances of `C` — `h` being exactly equivalent to `g`. Note that this practice usually only serves to confuse the reader of a program.

Methods may call other methods by using method attributes of the `self` argument:

```
class Bag:
    def __init__(self):
        self.data = []

    def add(self, x):
        self.data.append(x)

    def addtwice(self, x):
        self.add(x)
        self.add(x)
```

Methods may reference global names in the same way as ordinary functions. The global scope associated with a method is the module containing its definition. (A class is never used as a global scope.) While one rarely encounters a good reason for using global data in a method, there are many legitimate uses of the global scope: for one thing, functions and modules imported into the global scope can be used by methods, as well as functions and classes defined in it. Usually, the class containing the method is itself defined in this global scope, and in the next section we'll find some good reasons why a method would want to reference its own class.

Each value is an object, and therefore has a *class* (also called its *type*). It is stored as `object.__class__`.

## 9.5. Inheritance

Of course, a language feature would not be worthy of the name “class” without supporting inheritance. The syntax for a derived class definition looks like this:

```
class DerivedClassName(BaseClassName):
```

```
<statement-1>
.
.
.
<statement-N>
```

The name **BaseClassName** must be defined in a scope containing the derived class definition. In place of a base class name, other arbitrary expressions are also allowed. This can be useful, for example, when the base class is defined in another module:

```
class DerivedClassName(modname.BaseClassName):
```

Execution of a derived class definition proceeds the same as for a base class. When the class object is constructed, the base class is remembered. This is used for resolving attribute references: if a requested attribute is not found in the class, the search proceeds to look in the base class. This rule is applied recursively if the base class itself is derived from some other class.

There's nothing special about instantiation of derived classes: `DerivedClassName()` creates a new instance of the class. Method references are resolved as follows: the corresponding class attribute is searched, descending down the chain of base classes if necessary, and the method reference is valid if this yields a function object.

Derived classes may override methods of their base classes. Because methods have no special privileges when calling other methods of the same object, a method of a base class that calls another method defined in the same base class may end up calling a method of a derived class that overrides it. (For C++ programmers: all methods in Python are effectively `virtual`.)

An overriding method in a derived class may in fact want to extend rather than simply replace the base class method of the same name. There is a simple way to call the base class method directly: just call `BaseClassName.methodname(self, arguments)`. This is occasionally useful to clients as well. (Note that this only works if the base class is accessible as `BaseClassName` in the global scope.)

Python has two built-in functions that work with inheritance:

- Use `isinstance()` to check an instance's type:  
`isinstance(obj, int)` will be `True` only if `obj.__class__` is `int` or some class derived from `int`.
- Use `issubclass()` to check class inheritance:  
`issubclass(bool, int)` is `True` since `bool` is a subclass of `int`. However, `issubclass(float, int)` is `False` since `float` is not a subclass of `int`.

### 9.5.1. Multiple Inheritance

Python supports a form of multiple inheritance as well. A class definition with multiple base classes looks like this:

```
class DerivedClassName(Base1, Base2, Base3):  
    <statement-1>  
    .  
    .  
    .  
    <statement-N>
```

For most purposes, in the simplest cases, you can think of the search for attributes inherited from a parent class as depth-first, left-to-right, not searching twice in the same class where there is an overlap in the hierarchy. Thus, if an attribute is not found in **DerivedClassName**, it is searched for in **Base1**, then (recursively) in the base classes of **Base1**, and if it was not found there, it was searched for in **Base2**, and so on.

In fact, it is slightly more complex than that; the method resolution order changes dynamically to support cooperative calls to `super()`. This approach is known in some other multiple-inheritance languages as call-next-method and is more powerful than the `super` call found in single-inheritance languages.

Dynamic ordering is necessary because all cases of multiple inheritance exhibit one or more diamond relationships (where at least one of the parent classes can be accessed through multiple paths from the bottommost class). For example, all classes inherit

from **object**, so any case of multiple inheritance provides more than one path to reach **object**. To keep the base classes from being accessed more than once, the dynamic algorithm linearizes the search order in a way that preserves the left-to-right ordering specified in each class, that calls each parent only once, and that is monotonic (meaning that a class can be subclassed without affecting the precedence order of its parents). Taken together, these properties make it possible to design reliable and extensible classes with multiple inheritance. For more detail, see <https://www.python.org/download/releases/2.3/mro/>.

## 9.6. Private Variables

“Private” instance variables that cannot be accessed except from inside an object don’t exist in Python. However, there is a convention that is followed by most Python code: a name prefixed with an underscore (e.g. `_spam`) should be treated as a non-public part of the API (whether it is a function, a method or a data member). It should be considered an implementation detail and subject to change without notice.

Since there is a valid use-case for class-private members (namely to avoid name clashes of names with names defined by subclasses), there is limited support for such a mechanism, called *name mangling*. Any identifier of the form `__spam` (at least two leading underscores, at most one trailing underscore) is textually replaced with `_classname__spam`, where `classname` is the current class name with leading underscore(s) stripped. This mangling is done without regard to the syntactic position of the identifier, as long as it occurs within the definition of a class.

Name mangling is helpful for letting subclasses override methods without breaking intraclass method calls. For example:

```
class Mapping:
    def __init__(self, iterable):
        self.items_list = []
        self.__update(iterable)

    def update(self, iterable):
```

```

        for item in iterable:
            self.items_list.append(item)

    __update = update    # private copy of original update

class MappingSubclass(Mapping):

    def update(self, keys, values):
        # provides new signature for update()
        # but does not break __init__()
        for item in zip(keys, values):
            self.items_list.append(item)

```

The above example would work even if `MappingSubclass` were to introduce a `__update` identifier since it is replaced with `__Mapping__update` in the `Mapping` class and `__MappingSubclass__update` in the `MappingSubclass` class respectively.

Note that the mangling rules are designed mostly to avoid accidents; it still is possible to access or modify a variable that is considered private. This can even be useful in special circumstances, such as in the debugger.

Notice that code passed to `exec()` or `eval()` does not consider the classname of the invoking class to be the current class; this is similar to the effect of the `global` statement, the effect of which is likewise restricted to code that is byte-compiled together. The same restriction applies to `getattr()`, `setattr()` and `delattr()`, as well as when referencing `__dict__` directly.

## 9.7. Odds and Ends

Sometimes it is useful to have a data type similar to the Pascal “record” or C “struct”, bundling together a few named data items. The idiomatic approach is to use **dataclasses** for this purpose:

```

from dataclasses import dataclass

```

```
@dataclass
class Employee:
    name: str
    dept: str
    salary: int

>>> john = Employee('john', 'computer lab', 1000)
>>> john.dept
'computer lab'
>>> john.salary
1000
```

A piece of Python code that expects a particular abstract data type can often be passed a class that emulates the methods of that data type instead. For instance, if you have a function that formats some data from a file object, you can define a class with methods **read()** and **readline()** that get the data from a string buffer instead, and pass it as an argument.

Instance method objects have attributes, too: `m.__self__` is the instance object with the method `m()`, and `m.__func__` is the function object corresponding to the method.

## 9.8. Iterators

By now you have probably noticed that most container objects can be looped over using a **for** statement:

```
for element in [1, 2, 3]:
    print(element)
for element in (1, 2, 3):
    print(element)
for key in {'one':1, 'two':2}:
    print(key)
for char in "123":
    print(char)
for line in open("myfile.txt"):
    print(line, end='')
```

This style of access is clear, concise, and convenient. The use of iterators pervades and unifies Python. Behind the scenes, the `for` statement calls `iter()` on the container object. The function returns an iterator object that defines the method `__next__()` which accesses elements in the container one at a time. When there are no more elements, `__next__()` raises a `StopIteration` exception which tells the `for` loop to terminate. You can call the `__next__()` method using the `next()` built-in function; this example shows how it all works:

```
>>> s = 'abc'
>>> it = iter(s)
>>> it
<str_iterator object at 0x10c90e650>
>>> next(it)
'a'
>>> next(it)
'b'
>>> next(it)
'c'
>>> next(it)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    next(it)
StopIteration
```

Having seen the mechanics behind the iterator protocol, it is easy to add iterator behavior to your classes. Define an `__iter__()` method which returns an object with a `__next__()` method. If the class defines `__next__()`, then `__iter__()` can just return `self`:

```
class Reverse:
    """Iterator for looping over a sequence backwards."""
    def __init__(self, data):
        self.data = data
        self.index = len(data)

    def __iter__(self):
```

```

        return self

    def __next__(self):
        if self.index == 0:
            raise StopIteration
        self.index = self.index - 1
        return self.data[self.index]

>>> rev = Reverse('spam')
>>> iter(rev)
<__main__.Reverse object at 0x00A1DB50>
>>> for char in rev:
...     print(char)
...
m
a
p
s

```

## 9.9. Generators

**Generators** are a simple and powerful tool for creating iterators. They are written like regular functions but use the **yield** statement whenever they want to return data. Each time **next()** is called on it, the generator resumes where it left off (it remembers all the data values and which statement was last executed). An example shows that generators can be trivially easy to create:

```

def reverse(data):
    for index in range(len(data)-1, -1, -1):
        yield data[index]

>>> for char in reverse('golf'):
...     print(char)
...
f
l
o
g

```

Anything that can be done with generators can also be done with class-based iterators as described in the previous section. What makes generators so compact is that the `__iter__()` and `__next__()` methods are created automatically.

Another key feature is that the local variables and execution state are automatically saved between calls. This made the function easier to write and much more clear than an approach using instance variables like `self.index` and `self.data`.

In addition to automatic method creation and saving program state, when generators terminate, they automatically raise **StopIteration**. In combination, these features make it easy to create iterators with no more effort than writing a regular function.

## 9.10. Generator Expressions

Some simple generators can be coded succinctly as expressions using a syntax similar to list comprehensions but with parentheses instead of square brackets. These expressions are designed for situations where the generator is used right away by an enclosing function. Generator expressions are more compact but less versatile than full generator definitions and tend to be more memory friendly than equivalent list comprehensions.

Examples:

```
>>> sum(i*i for i in range(10))                # sum of squares
285

>>> xvec = [10, 20, 30]
>>> yvec = [7, 5, 3]
>>> sum(x*y for x,y in zip(xvec, yvec))         # dot product
260

>>> unique_words = set(word for line in page for word in line.split())

>>> valedictorian = max((student.gpa, student.name) for student in graduates)

>>> data = 'golf'
```

```
>>> list(data[i] for i in range(len(data)-1, -1, -1))  
['f', 'l', 'o', 'g']
```

## Footnotes

1

Except for one thing. Module objects have a secret read-only attribute called `__dict__` which returns the dictionary used to implement the module's namespace; the name `__dict__` is an attribute but not a global name. Obviously, using this violates the abstraction of namespace implementation, and should be restricted to things like post-mortem debuggers.

# 10. Brief Tour of the Standard Library

## 10.1. Operating System Interface

The `os` module provides dozens of functions for interacting with the operating system:

```
>>> import os
>>> os.getcwd()          # Return the current working directory
'C:\\Python311'
>>> os.chdir('/server/accesslogs')  # Change current working directory
>>> os.system('mkdir today')        # Run the command mkdir today
0
```

Be sure to use the `import os` style instead of `from os import *`. This will keep `os.open()` from shadowing the built-in `open()` function which operates much differently.

The built-in `dir()` and `help()` functions are useful as interactive aids for working with large modules like `os`:

```
>>> import os
>>> dir(os)
<returns a list of all module functions>
>>> help(os)
<returns an extensive manual page created from the module's docstrings>
```

For daily file and directory management tasks, the `shutil` module provides a higher level interface that is easier to use:

```
>>> import shutil
>>> shutil.copyfile('data.db', 'archive.db')
'archive.db'
>>> shutil.move('/build/executables', 'installdir')
```

```
'installdir'
```

## 10.2. File Wildcards

The **glob** module provides a function for making file lists from directory wildcard searches:

```
>>> import glob
>>> glob.glob('*.py')
['primes.py', 'random.py', 'quote.py']
```

## 10.3. Command Line Arguments

Common utility scripts often need to process command line arguments. These arguments are stored in the **sys** module's *argv* attribute as a list. For instance the following output results from running `python demo.py one two three` at the command line:

```
>>> import sys
>>> print(sys.argv)
['demo.py', 'one', 'two', 'three']
```

The **argparse** module provides a more sophisticated mechanism to process command line arguments. The following script extracts one or more filenames and an optional number of lines to be displayed:

```
import argparse

parser = argparse.ArgumentParser(
    prog='top',
    description='Show top lines from each file')
parser.add_argument('filenames', nargs='+')
parser.add_argument('-l', '--lines', type=int, default=1)
args = parser.parse_args()
print(args)
```

When run at the command line with `python top.py --`

`lines=5` `alpha.txt` `beta.txt`, the script sets `args.lines` to 5 and `args filenames` to `['alpha.txt', 'beta.txt']`.

## 10.4. Error Output Redirection and Program Termination

The **sys** module also has attributes for *stdin*, *stdout*, and *stderr*. The latter is useful for emitting warnings and error messages to make them visible even when *stdout* has been redirected:

```
>>> sys.stderr.write('Warning, log file not found starting a new one')
Warning, log file not found starting a new one
```

The most direct way to terminate a script is to use `sys.exit()`.

## 10.5. String Pattern Matching

The **re** module provides regular expression tools for advanced string processing. For complex matching and manipulation, regular expressions offer succinct, optimized solutions:

```
>>> import re
>>> re.findall(r'\b[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
>>> re.sub(r'(\b[a-z]+) \1', r'\1', 'cat in the the hat the hat')
'cat in the hat'
```

When only simple capabilities are needed, string methods are preferred because they are easier to read and debug:

```
>>> 'tea for too'.replace('too', 'two')
'tea for two'
```

## 10.6. Mathematics

The **math** module gives access to the underlying C library functions for floating point math:

```
>>> import math
>>> math.cos(math.pi / 4)
0.70710678118654757
>>> math.log(1024, 2)
10.0
```

The **random** module provides tools for making random selections:

```
>>> import random
>>> random.choice(['apple', 'pear', 'banana'])
'apple'
>>> random.sample(range(100), 10)    # sampling without r
[30, 83, 16, 4, 8, 81, 41, 50, 18, 33]
>>> random.random()                  # random float
0.17970987693706186
>>> random.randrange(6)              # random integer chosen from
4
```

The **statistics** module calculates basic statistical properties (the mean, median, variance, etc.) of numeric data:

```
>>> import statistics
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> statistics.mean(data)
1.6071428571428572
>>> statistics.median(data)
1.25
>>> statistics.variance(data)
1.3720238095238095
```

The SciPy project <<https://scipy.org>> has many other modules for numerical computations.

## 10.7. Internet Access

There are a number of modules for accessing the internet and processing internet protocols. Two of the simplest are **urllib.request** for retrieving data from URLs and **smtplib** for sending mail:

```

>>> from urllib.request import urlopen
>>> with urlopen('http://worldtimeapi.org/api/timezone/e
...     for line in response:
...         line = line.decode()                # Convert b
...         if line.startswith('datetime'):
...             print(line.rstrip())            # Remove tr
...
datetime: 2022-01-01T01:36:47.689215+00:00

>>> import smtplib
>>> server = smtplib.SMTP('localhost')
>>> server.sendmail('soothsayer@example.org', 'jcaesar@e
... """To: jcaesar@example.org
... From: soothsayer@example.org
...
... Beware the Ides of March.
... """)
>>> server.quit()

```

(Note that the second example needs a mailserver running on localhost.)

## 10.8. Dates and Times

The `datetime` module supplies classes for manipulating dates and times in both simple and complex ways. While date and time arithmetic is supported, the focus of the implementation is on efficient member extraction for output formatting and manipulation. The module also supports objects that are timezone aware.

```

>>> # dates are easily constructed and formatted
>>> from datetime import date
>>> now = date.today()
>>> now
datetime.date(2003, 12, 2)
>>> now.strftime("%m-%d-%y. %d %b %Y is a %A on the %d o
'12-02-03. 02 Dec 2003 is a Tuesday on the 02 day of Dec

```

```
>>> # dates support calendar arithmetic
>>> birthday = date(1964, 7, 31)
>>> age = now - birthday
>>> age.days
14368
```

## 10.9. Data Compression

Common data archiving and compression formats are directly supported by modules including: **zlib**, **gzip**, **bz2**, **lzma**, **zipfile** and **tarfile**.

```
>>> import zlib
>>> s = b'witch which has which witches wrist watch'
>>> len(s)
41
>>> t = zlib.compress(s)
>>> len(t)
37
>>> zlib.decompress(t)
b'witch which has which witches wrist watch'
>>> zlib.crc32(s)
226805979
```

## 10.10. Performance Measurement

Some Python users develop a deep interest in knowing the relative performance of different approaches to the same problem. Python provides a measurement tool that answers those questions immediately.

For example, it may be tempting to use the tuple packing and unpacking feature instead of the traditional approach to swapping arguments. The **timeit** module quickly demonstrates a modest performance advantage:

```
>>> from timeit import Timer
>>> Timer('t=a; a=b; b=t', 'a=1; b=2').timeit()
0.57535828626024577
```

```
>>> Timer('a,b = b,a', 'a=1; b=2').timeit()  
0.54962537085770791
```

In contrast to `timeit`'s fine level of granularity, the `profile` and `pstats` modules provide tools for identifying time critical sections in larger blocks of code.

## 10.11. Quality Control

One approach for developing high quality software is to write tests for each function as it is developed and to run those tests frequently during the development process.

The `doctest` module provides a tool for scanning a module and validating tests embedded in a program's docstrings. Test construction is as simple as cutting-and-pasting a typical call along with its results into the docstring. This improves the documentation by providing the user with an example and it allows the `doctest` module to make sure the code remains true to the documentation:

```
def average(values):  
    """Computes the arithmetic mean of a list of numbers  
  
    >>> print(average([20, 30, 70]))  
    40.0  
    """  
    return sum(values) / len(values)
```

```
import doctest  
doctest.testmod() # automatically validate the embedded
```

The `unittest` module is not as effortless as the `doctest` module, but it allows a more comprehensive set of tests to be maintained in a separate file:

```
import unittest  
  
class TestStatisticalFunctions(unittest.TestCase):  
  
    def test_average(self):
```

```

self.assertEqual(average([20, 30, 70]), 40.0)
self.assertEqual(round(average([1, 5, 7]), 1), 4)
with self.assertRaises(ZeroDivisionError):
    average([])
with self.assertRaises(TypeError):
    average(20, 30, 70)

```

```

unittest.main() # Calling from the command line invokes

```

## 10.12. Batteries Included

Python has a “batteries included” philosophy. This is best seen through the sophisticated and robust capabilities of its larger packages. For example:

- The `xmlrpc.client` and `xmlrpc.server` modules make implementing remote procedure calls into an almost trivial task. Despite the modules’ names, no direct knowledge or handling of XML is needed.
- The `email` package is a library for managing email messages, including MIME and other [RFC 2822](https://datatracker.ietf.org/doc/html/rfc2822.html) [https://datatracker.ietf.org/doc/html/rfc2822.html]-based message documents. Unlike `smtplib` and `poplib` which actually send and receive messages, the email package has a complete toolset for building or decoding complex message structures (including attachments) and for implementing internet encoding and header protocols.
- The `json` package provides robust support for parsing this popular data interchange format. The `csv` module supports direct reading and writing of files in Comma-Separated Value format, commonly supported by databases and spreadsheets. XML processing is supported by the `xml.etree.ElementTree`, `xml.dom` and `xml.sax` packages. Together, these modules and packages greatly simplify data interchange between Python applications and other tools.
- The `sqlite3` module is a wrapper for the SQLite database library, providing a persistent database that can be updated and accessed using slightly nonstandard SQL syntax.

- Internationalization is supported by a number of modules including `gettext`, `locale`, and the `codecs` package.

# 11. Brief Tour of the Standard Library — Part II

This second tour covers more advanced modules that support professional programming needs. These modules rarely occur in small scripts.

## 11.1. Output Formatting

The `reprlib` module provides a version of `repr()` customized for abbreviated displays of large or deeply nested containers:

```
>>> import reprlib
>>> reprlib.repr(set('supercalifragilisticexpialidocious
{'a', 'c', 'd', 'e', 'f', 'g', ...})"
```

The `pprint` module offers more sophisticated control over printing both built-in and user defined objects in a way that is readable by the interpreter. When the result is longer than one line, the “pretty printer” adds line breaks and indentation to more clearly reveal data structure:

```
>>> import pprint
>>> t = [[['black', 'cyan'], 'white', ['green', 'red']]
...      'yellow'], 'blue']]
...
>>> pprint.pprint(t, width=30)
[[['black', 'cyan'],
  'white',
  ['green', 'red']],
 ['magenta', 'yellow'],
 'blue']]
```

The `textwrap` module formats paragraphs of text to fit a given

screen width:

```
>>> import textwrap
>>> doc = """The wrap() method is just like fill() except
... a list of strings instead of one big string with new
... the wrapped lines."""
...
>>> print(textwrap.fill(doc, width=40))
The wrap() method is just like fill()
except that it returns a list of strings
instead of one big string with newlines
to separate the wrapped lines.
```

The **locale** module accesses a database of culture specific data formats. The grouping attribute of locale's format function provides a direct way of formatting numbers with group separators:

```
>>> import locale
>>> locale.setlocale(locale.LC_ALL, 'English_United States.1252')
>>> conv = locale.localeconv() # get a mapping
>>> x = 1234567.8
>>> locale.format("%d", x, grouping=True)
'1,234,567'
>>> locale.format_string("%s%.*f", (conv['currency_symbol'],
... conv['frac_digits'], x), groupi
'$1,234,567.80'
```

## 11.2. Templating

The **string** module includes a versatile **Template** class with a simplified syntax suitable for editing by end-users. This allows users to customize their applications without having to alter the application.

The format uses placeholder names formed by `$` with valid Python identifiers (alphanumeric characters and underscores). Surrounding the placeholder with braces allows it to be followed by more alphanumeric letters with no intervening spaces. Writing `$$`

creates a single escaped \$:

```
>>> from string import Template
>>> t = Template('${village}folk send $$10 to $cause.')
>>> t.substitute(village='Nottingham', cause='the ditch
'Nottinghamfolk send $10 to the ditch fund.'
```

The `substitute()` method raises a `KeyError` when a placeholder is not supplied in a dictionary or a keyword argument. For mail-merge style applications, user supplied data may be incomplete and the `safe_substitute()` method may be more appropriate — it will leave placeholders unchanged if data is missing:

```
>>> t = Template('Return the $item to $owner.')
>>> d = dict(item='unladen swallow')
>>> t.substitute(d)
Traceback (most recent call last):
...
KeyError: 'owner'
>>> t.safe_substitute(d)
'Return the unladen swallow to $owner.'
```

Template subclasses can specify a custom delimiter. For example, a batch renaming utility for a photo browser may elect to use percent signs for placeholders such as the current date, image sequence number, or file format:

```
>>> import time, os.path
>>> photofiles = ['img_1074.jpg', 'img_1076.jpg', 'img_1
>>> class BatchRename(Template):
...     delimiter = '%'
...
>>> fmt = input('Enter rename style (%d-date %n-seqnum %f-format): ')
Enter rename style (%d-date %n-seqnum %f-format): Ashle

>>> t = BatchRename(fmt)
>>> date = time.strftime('%d%b%y')
>>> for i, filename in enumerate(photofiles):
...     base, ext = os.path.splitext(filename)
```

```

...     newname = t.substitute(d=date, n=i, f=ext)
...     print('{0} --> {1}'.format(filename, newname))

img_1074.jpg --> Ashley_0.jpg
img_1076.jpg --> Ashley_1.jpg
img_1077.jpg --> Ashley_2.jpg

```

Another application for templating is separating program logic from the details of multiple output formats. This makes it possible to substitute custom templates for XML files, plain text reports, and HTML web reports.

## 11.3. Working with Binary Data Record Layouts

The `struct` module provides `pack()` and `unpack()` functions for working with variable length binary record formats. The following example shows how to loop through header information in a ZIP file without using the `zipfile` module. Pack codes "H" and "I" represent two and four byte unsigned numbers respectively. The "<" indicates that they are standard size and in little-endian byte order:

```

import struct

with open('myfile.zip', 'rb') as f:
    data = f.read()

start = 0
for i in range(3):
    start += 14
    fields = struct.unpack('<IIIHH', data[start:start+16])
    crc32, comp_size, uncomp_size, filenamesize, extra_size = fields

    start += 16
    filename = data[start:start+filenamesize]
    start += filenamesize
    extra = data[start:start+extra_size]

```

```
print(filename, hex(crc32), comp_size, uncomp_size)

start += extra_size + comp_size      # skip to the ne
```

## 11.4. Multi-threading

Threading is a technique for decoupling tasks which are not sequentially dependent. Threads can be used to improve the responsiveness of applications that accept user input while other tasks run in the background. A related use case is running I/O in parallel with computations in another thread.

The following code shows how the high level `threading` module can run tasks in background while the main program continues to run:

```
import threading, zipfile

class AsyncZip(threading.Thread):
    def __init__(self, infile, outfile):
        threading.Thread.__init__(self)
        self.infile = infile
        self.outfile = outfile

    def run(self):
        f = zipfile.ZipFile(self.outfile, 'w', zipfile.ZIP_DEFLATED)
        f.write(self.infile)
        f.close()
        print('Finished background zip of:', self.infile)

background = AsyncZip('mydata.txt', 'myarchive.zip')
background.start()
print('The main program continues to run in foreground.')

background.join()    # Wait for the background task to finish
print('Main program waited until background was done.')
```

The principal challenge of multi-threaded applications is coordinating threads that share data or other resources. To that end,

the `threading` module provides a number of synchronization primitives including locks, events, condition variables, and semaphores.

While those tools are powerful, minor design errors can result in problems that are difficult to reproduce. So, the preferred approach to task coordination is to concentrate all access to a resource in a single thread and then use the `queue` module to feed that thread with requests from other threads. Applications using `Queue` objects for inter-thread communication and coordination are easier to design, more readable, and more reliable.

## 11.5. Logging

The `logging` module offers a full featured and flexible logging system. At its simplest, log messages are sent to a file or to `sys.stderr`:

```
import logging
logging.debug('Debugging information')
logging.info('Informational message')
logging.warning('Warning:config file %s not found', 'server.conf')
logging.error('Error occurred')
logging.critical('Critical error -- shutting down')
```

This produces the following output:

```
WARNING:root:Warning:config file server.conf not found
ERROR:root:Error occurred
CRITICAL:root:Critical error -- shutting down
```

By default, informational and debugging messages are suppressed and the output is sent to standard error. Other output options include routing messages through email, datagrams, sockets, or to an HTTP Server. New filters can select different routing based on message priority: **DEBUG**, **INFO**, **WARNING**, **ERROR**, and **CRITICAL**.

The logging system can be configured directly from Python or can be loaded from a user editable configuration file for customized

logging without altering the application.

## 11.6. Weak References

Python does automatic memory management (reference counting for most objects and [garbage collection](#) to eliminate cycles). The memory is freed shortly after the last reference to it has been eliminated.

This approach works fine for most applications but occasionally there is a need to track objects only as long as they are being used by something else. Unfortunately, just tracking them creates a reference that makes them permanent. The [weakref](#) module provides tools for tracking objects without creating a reference. When the object is no longer needed, it is automatically removed from a weakref table and a callback is triggered for weakref objects. Typical applications include caching objects that are expensive to create:

```
>>> import weakref, gc
>>> class A:
...     def __init__(self, value):
...         self.value = value
...     def __repr__(self):
...         return str(self.value)
...
>>> a = A(10)                                # create a reference
>>> d = weakref.WeakValueDictionary()
>>> d['primary'] = a                          # does not create a reference
>>> d['primary']                              # fetch the object if it exists
10
>>> del a                                    # remove the one reference
>>> gc.collect()                            # run garbage collection
0
>>> d['primary']                             # entry was automatically removed
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>

```

```
o = self.data[key]()
KeyError: 'primary'
```

## 11.7. Tools for Working with Lists

Many data structure needs can be met with the built-in list type. However, sometimes there is a need for alternative implementations with different performance trade-offs.

The `array` module provides an `array()` object that is like a list that stores only homogeneous data and stores it more compactly. The following example shows an array of numbers stored as two byte unsigned binary numbers (typecode "H") rather than the usual 16 bytes per entry for regular lists of Python int objects:

```
>>> from array import array
>>> a = array('H', [4000, 10, 700, 22222])
>>> sum(a)
26932
>>> a[1:3]
array('H', [10, 700])
```

The `collections` module provides a `deque()` object that is like a list with faster appends and pops from the left side but slower lookups in the middle. These objects are well suited for implementing queues and breadth first tree searches:

```
>>> from collections import deque
>>> d = deque(["task1", "task2", "task3"])
>>> d.append("task4")
>>> print("Handling", d.popleft())
Handling task1
```

```
unsearched = deque([starting_node])
def breadth_first_search(unsearched):
    node = unsearched.popleft()
    for m in gen_moves(node):
        if is_goal(m):
            return m
```

```
unsearched.append(m)
```

In addition to alternative list implementations, the library also offers other tools such as the `bisect` module with functions for manipulating sorted lists:

```
>>> import bisect
>>> scores = [(100, 'perl'), (200, 'tcl'), (400, 'lua'),
>>> bisect.insort(scores, (300, 'ruby'))
>>> scores
[(100, 'perl'), (200, 'tcl'), (300, 'ruby'), (400, 'lua')]
```

The `heapq` module provides functions for implementing heaps based on regular lists. The lowest valued entry is always kept at position zero. This is useful for applications which repeatedly access the smallest element but do not want to run a full list sort:

```
>>> from heapq import heapify, heappop, heappush
>>> data = [1, 3, 5, 7, 9, 2, 4, 6, 8, 0]
>>> heapify(data)                                # rearrange the list
>>> heappush(data, -5)                            # add a new entry
>>> [heappop(data) for i in range(3)]             # fetch the three
[-5, 0, 1]
```

## 11.8. Decimal Floating Point Arithmetic

The `decimal` module offers a `Decimal` datatype for decimal floating point arithmetic. Compared to the built-in `float` implementation of binary floating point, the class is especially helpful for

- financial applications and other uses which require exact decimal representation,
- control over precision,
- control over rounding to meet legal or regulatory requirements,
- tracking of significant decimal places, or
- applications where the user expects the results to match calculations done by hand.

For example, calculating a 5% tax on a 70 cent phone charge gives different results in decimal floating point and binary floating point. The difference becomes significant if the results are rounded to the nearest cent:

```
>>> from decimal import *
>>> round(Decimal('0.70') * Decimal('1.05'), 2)
Decimal('0.74')
>>> round(.70 * 1.05, 2)
0.73
```

The **Decimal** result keeps a trailing zero, automatically inferring four place significance from multiplicands with two place significance. Decimal reproduces mathematics as done by hand and avoids issues that can arise when binary floating point cannot exactly represent decimal quantities.

Exact representation enables the **Decimal** class to perform modulo calculations and equality tests that are unsuitable for binary floating point:

```
>>> Decimal('1.00') % Decimal('.10')
Decimal('0.00')
>>> 1.00 % 0.10
0.099999999999999995

>>> sum([Decimal('0.1')]*10) == Decimal('1.0')
True
>>> sum([0.1]*10) == 1.0
False
```

The **decimal** module provides arithmetic with as much precision as needed:

```
>>> getcontext().prec = 36
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857')
```

# 12. Virtual Environments and Packages

## 12.1. Introduction

Python applications will often use packages and modules that don't come as part of the standard library. Applications will sometimes need a specific version of a library, because the application may require that a particular bug has been fixed or the application may be written using an obsolete version of the library's interface.

This means it may not be possible for one Python installation to meet the requirements of every application. If application A needs version 1.0 of a particular module but application B needs version 2.0, then the requirements are in conflict and installing either version 1.0 or 2.0 will leave one application unable to run.

The solution for this problem is to create a [virtual environment](#), a self-contained directory tree that contains a Python installation for a particular version of Python, plus a number of additional packages.

Different applications can then use different virtual environments. To resolve the earlier example of conflicting requirements, application A can have its own virtual environment with version 1.0 installed while application B has another virtual environment with version 2.0. If application B requires a library be upgraded to version 3.0, this will not affect application A's environment.

## 12.2. Creating Virtual Environments

The module used to create and manage virtual environments is called [venv](#). [venv](#) will usually install the most recent version of Python that you have available. If you have multiple versions of

Python on your system, you can select a specific Python version by running `python3` or whichever version you want.

To create a virtual environment, decide upon a directory where you want to place it, and run the `venv` module as a script with the directory path:

```
python -m venv tutorial-env
```

This will create the `tutorial-env` directory if it doesn't exist, and also create directories inside it containing a copy of the Python interpreter and various supporting files.

A common directory location for a virtual environment is `.venv`. This name keeps the directory typically hidden in your shell and thus out of the way while giving it a name that explains why the directory exists. It also prevents clashing with `.env` environment variable definition files that some tooling supports.

Once you've created a virtual environment, you may activate it.

On Windows, run:

```
tutorial-env\Scripts\activate.bat
```

On Unix or MacOS, run:

```
source tutorial-env/bin/activate
```

(This script is written for the bash shell. If you use the **csh** or **fish** shells, there are alternate `activate.csh` and `activate.fish` scripts you should use instead.)

Activating the virtual environment will change your shell's prompt to show what virtual environment you're using, and modify the environment so that running `python` will get you that particular version and installation of Python. For example:

```
$ source ~/envs/tutorial-env/bin/activate
(tutorial-env) $ python
Python 3.5.1 (default, May  6 2016, 10:59:36)
...
```

```
>>> import sys
>>> sys.path
['', '/usr/local/lib/python35.zip', ...,
 '~/.envs/tutorial-env/lib/python3.5/site-packages']
>>>
```

To deactivate a virtual environment, type:

```
deactivate
```

into the terminal.

## 12.3. Managing Packages with pip

You can install, upgrade, and remove packages using a program called **pip**. By default `pip` will install packages from the [Python Package Index](https://pypi.org) [https://pypi.org]. You can browse the Python Package Index by going to it in your web browser.

`pip` has a number of subcommands: “install”, “uninstall”, “freeze”, etc. (Consult the [Installing Python Modules](#) guide for complete documentation for `pip`.)

You can install the latest version of a package by specifying a package’s name:

```
(tutorial-env) $ python -m pip install novas
Collecting novas
  Downloading novas-3.1.1.3.tar.gz (136kB)
Installing collected packages: novas
  Running setup.py install for novas
Successfully installed novas-3.1.1.3
```

You can also install a specific version of a package by giving the package name followed by `==` and the version number:

```
(tutorial-env) $ python -m pip install requests==2.6.0
Collecting requests==2.6.0
  Using cached requests-2.6.0-py2.py3-none-any.whl
Installing collected packages: requests
```

Successfully installed requests-2.6.0

If you re-run this command, pip will notice that the requested version is already installed and do nothing. You can supply a different version number to get that version, or you can run `python -m pip install --upgrade` to upgrade the package to the latest version:

```
(tutorial-env) $ python -m pip install --upgrade requests
Collecting requests
Installing collected packages: requests
  Found existing installation: requests 2.6.0
    Uninstalling requests-2.6.0:
      Successfully uninstalled requests-2.6.0
Successfully installed requests-2.7.0
```

`python -m pip uninstall` followed by one or more package names will remove the packages from the virtual environment.

`python -m pip show` will display information about a particular package:

```
(tutorial-env) $ python -m pip show requests
---
Metadata-Version: 2.0
Name: requests
Version: 2.7.0
Summary: Python HTTP for Humans.
Home-page: http://python-requests.org
Author: Kenneth Reitz
Author-email: me@kennethreitz.com
License: Apache 2.0
Location: /Users/akuchling/envs/tutorial-env/lib/python3
Requires:
```

`python -m pip list` will display all of the packages installed in the virtual environment:

```
(tutorial-env) $ python -m pip list
novas (3.1.1.3)
```

```
numpy (1.9.2)
pip (7.0.3)
requests (2.7.0)
setuptools (16.0)
```

`python -m pip freeze` will produce a similar list of the installed packages, but the output uses the format that `python -m pip install` expects. A common convention is to put this list in a `requirements.txt` file:

```
(tutorial-env) $ python -m pip freeze > requirements.txt
(tutorial-env) $ cat requirements.txt
novas==3.1.1.3
numpy==1.9.2
requests==2.7.0
```

The `requirements.txt` can then be committed to version control and shipped as part of an application. Users can then install all the necessary packages with `install -r`:

```
(tutorial-env) $ python -m pip install -r requirements.txt
Collecting novas==3.1.1.3 (from -r requirements.txt (line 1))
...
Collecting numpy==1.9.2 (from -r requirements.txt (line 2))
...
Collecting requests==2.7.0 (from -r requirements.txt (line 3))
...
Installing collected packages: novas, numpy, requests
Running setup.py install for novas
Successfully installed novas-3.1.1.3 numpy-1.9.2 request
```

`pip` has many more options. Consult the [Installing Python Modules](#) guide for complete documentation for `pip`. When you've written a package and want to make it available on the Python Package Index, consult the [Distributing Python Modules](#) guide.

# 13. What Now?

Reading this tutorial has probably reinforced your interest in using Python — you should be eager to apply Python to solving your real-world problems. Where should you go to learn more?

This tutorial is part of Python's documentation set. Some other documents in the set are:

- [The Python Standard Library](#):

You should browse through this manual, which gives complete (though terse) reference material about types, functions, and the modules in the standard library. The standard Python distribution includes a *lot* of additional code. There are modules to read Unix mailboxes, retrieve documents via HTTP, generate random numbers, parse command-line options, compress data, and many other tasks. Skimming through the Library Reference will give you an idea of what's available.

- [Installing Python Modules](#) explains how to install additional modules written by other Python users.
- [The Python Language Reference](#): A detailed explanation of Python's syntax and semantics. It's heavy reading, but is useful as a complete guide to the language itself.

More Python resources:

- <https://www.python.org>: The major Python web site. It contains code, documentation, and pointers to Python-related pages around the web.
- <https://docs.python.org>: Fast access to Python's documentation.
- <https://pypi.org>: The Python Package Index, previously also nicknamed the Cheese Shop [1](#), is an index of user-created

Python modules that are available for download. Once you begin releasing code, you can register it here so that others can find it.

- <https://code.activestate.com/recipes/langs/python/>: The Python Cookbook is a sizable collection of code examples, larger modules, and useful scripts. Particularly notable contributions are collected in a book also titled Python Cookbook (O'Reilly & Associates, ISBN 0-596-00797-3.)
- <https://pyvideo.org> collects links to Python-related videos from conferences and user-group meetings.
- <https://scipy.org>: The Scientific Python project includes modules for fast array computations and manipulations plus a host of packages for such things as linear algebra, Fourier transforms, non-linear solvers, random number distributions, statistical analysis and the like.

For Python-related questions and problem reports, you can post to the newsgroup *comp.lang.python*, or send them to the mailing list at [python-list@python.org](mailto:python-list@python.org). The newsgroup and mailing list are gatewayed, so messages posted to one will automatically be forwarded to the other. There are hundreds of postings a day, asking (and answering) questions, suggesting new features, and announcing new modules. Mailing list archives are available at <https://mail.python.org/pipermail/>.

Before posting, be sure to check the list of [Frequently Asked Questions](#) (also called the FAQ). The FAQ answers many of the questions that come up again and again, and may already contain the solution for your problem.

## Footnotes

1

“Cheese Shop” is a Monty Python’s sketch: a customer enters a cheese shop, but whatever cheese he asks for, the clerk says it’s missing.

# 14. Interactive Input Editing and History Substitution

Some versions of the Python interpreter support editing of the current input line and history substitution, similar to facilities found in the Korn shell and the GNU Bash shell. This is implemented using the [GNU Readline](https://tiswww.case.edu/php/chet/readline/rltop.html) [https://tiswww.case.edu/php/chet/readline/rltop.html] library, which supports various styles of editing. This library has its own documentation which we won't duplicate here.

## 14.1. Tab Completion and History Editing

Completion of variable and module names is [automatically enabled](#) at interpreter startup so that the `Tab` key invokes the completion function; it looks at Python statement names, the current local variables, and the available module names. For dotted expressions such as `string.a`, it will evaluate the expression up to the final `'.'` and then suggest completions from the attributes of the resulting object. Note that this may execute application-defined code if an object with a `__getattr__()` method is part of the expression. The default configuration also saves your history into a file named `.python_history` in your user directory. The history will be available again during the next interactive interpreter session.

## 14.2. Alternatives to the Interactive Interpreter

This facility is an enormous step forward compared to earlier versions of the interpreter; however, some wishes are left: It would be nice if the proper indentation were suggested on continuation lines (the parser knows if an indent token is required next). The completion mechanism might use the interpreter's symbol table. A

command to check (or even suggest) matching parentheses, quotes, etc., would also be useful.

One alternative enhanced interactive interpreter that has been around for quite some time is [IPython](https://ipython.org/) [https://ipython.org/], which features tab completion, object exploration and advanced history management. It can also be thoroughly customized and embedded into other applications. Another similar enhanced interactive environment is [bpython](https://www.bpython-interpreter.org/) [https://www.bpython-interpreter.org/].

## 15. Floating Point Arithmetic: Issues and Limitations

Floating-point numbers are represented in computer hardware as base 2 (binary) fractions. For example, the **decimal** fraction  $0.125$  has value  $1/10 + 2/100 + 5/1000$ , and in the same way the **binary** fraction  $0.001$  has value  $0/2 + 0/4 + 1/8$ . These two fractions have identical values, the only real difference being that the first is written in base 10 fractional notation, and the second in base 2.

Unfortunately, most decimal fractions cannot be represented exactly as binary fractions. A consequence is that, in general, the decimal floating-point numbers you enter are only approximated by the binary floating-point numbers actually stored in the machine.

The problem is easier to understand at first in base 10. Consider the fraction  $1/3$ . You can approximate that as a base 10 fraction:

$0.3$

or, better,

$0.33$

or, better,

$0.333$

and so on. No matter how many digits you're willing to write down, the result will never be exactly  $1/3$ , but will be an increasingly better approximation of  $1/3$ .

In the same way, no matter how many base 2 digits you're willing to use, the decimal value  $0.1$  cannot be represented exactly as a base 2 fraction. In base 2,  $1/10$  is the infinitely repeating fraction

```
0.000110011001100110011001100110011001100110011001100110011...
```

Stop at any finite number of bits, and you get an approximation. On most machines today, floats are approximated using a binary fraction with the numerator using the first 53 bits starting with the most significant bit and with the denominator as a power of two. In the case of  $1/10$ , the binary fraction is  $3602879701896397 / 2^{55}$  which is close to but not exactly equal to the true value of  $1/10$ .

Many users are not aware of the approximation because of the way values are displayed. Python only prints a decimal approximation to the true decimal value of the binary approximation stored by the machine. On most machines, if Python were to print the true decimal value of the binary approximation stored for  $0.1$ , it would have to display

```
>>> 0.1
0.100000000000000005551115123125782702118158340454101562
```

That is more digits than most people find useful, so Python keeps the number of digits manageable by displaying a rounded value instead

```
>>> 1 / 10
0.1
```

Just remember, even though the printed result looks like the exact value of  $1/10$ , the actual stored value is the nearest representable binary fraction.

Interestingly, there are many different decimal numbers that share the same nearest approximate binary fraction. For example, the numbers  $0.1$  and  $0.100000000000000001$  and

```
0.100000000000000005551115123125782702118158340454101562
```

are all approximated by  $3602879701896397 / 2^{55}$ . Since all of these decimal values share the same approximation, any one of them could be displayed while still preserving the invariant `eval(repr(x)) == x`.

Historically, the Python prompt and built-in `repr()` function

would choose the one with 17 significant digits, 0.100000000000000001. Starting with Python 3.1, Python (on most systems) is now able to choose the shortest of these and simply display 0.1.

Note that this is in the very nature of binary floating-point: this is not a bug in Python, and it is not a bug in your code either. You'll see the same kind of thing in all languages that support your hardware's floating-point arithmetic (although some languages may not *display* the difference by default, or in all output modes).

For more pleasant output, you may wish to use string formatting to produce a limited number of significant digits:

```
>>> format(math.pi, '.12g') # give 12 significant digits
'3.14159265359'
```

```
>>> format(math.pi, '.2f')   # give 2 digits after the p
'3.14'
```

```
>>> repr(math.pi)
'3.141592653589793'
```

It's important to realize that this is, in a real sense, an illusion: you're simply rounding the *display* of the true machine value.

One illusion may beget another. For example, since 0.1 is not exactly 1/10, summing three values of 0.1 may not yield exactly 0.3, either:

```
>>> .1 + .1 + .1 == .3
False
```

Also, since the 0.1 cannot get any closer to the exact value of 1/10 and 0.3 cannot get any closer to the exact value of 3/10, then pre-rounding with `round()` function cannot help:

```
>>> round(.1, 1) + round(.1, 1) + round(.1, 1) == round(
False
```

Though the numbers cannot be made closer to their intended exact

values, the `round()` function can be useful for post-rounding so that results with inexact values become comparable to one another:

```
>>> round(.1 + .1 + .1, 10) == round(.3, 10)
True
```

Binary floating-point arithmetic holds many surprises like this. The problem with “0.1” is explained in precise detail below, in the “Representation Error” section. See [Examples of Floating Point Problems](https://jvns.ca/blog/2023/01/13/examples-of-floating-point-problems/) [https://jvns.ca/blog/2023/01/13/examples-of-floating-point-problems/] for a pleasant summary of how binary floating-point works and the kinds of problems commonly encountered in practice. Also see [The Perils of Floating Point](https://www.lahey.com/float.htm) [https://www.lahey.com/float.htm] for a more complete account of other common surprises.

As that says near the end, “there are no easy answers.” Still, don’t be unduly wary of floating-point! The errors in Python float operations are inherited from the floating-point hardware, and on most machines are on the order of no more than 1 part in  $2^{53}$  per operation. That’s more than adequate for most tasks, but you do need to keep in mind that it’s not decimal arithmetic and that every float operation can suffer a new rounding error.

While pathological cases do exist, for most casual use of floating-point arithmetic you’ll see the result you expect in the end if you simply round the display of your final results to the number of decimal digits you expect. `str()` usually suffices, and for finer control see the `str.format()` method’s format specifiers in [Format String Syntax](#).

For use cases which require exact decimal representation, try using the `decimal` module which implements decimal arithmetic suitable for accounting applications and high-precision applications.

Another form of exact arithmetic is supported by the `fractions` module which implements arithmetic based on rational numbers (so the numbers like  $1/3$  can be represented exactly).

If you are a heavy user of floating-point operations you should take a look at the NumPy package and many other packages for mathematical and statistical operations supplied by the SciPy

project. See <<https://scipy.org>>.

Python provides tools that may help on those rare occasions when you really *do* want to know the exact value of a float. The `float.as_integer_ratio()` method expresses the value of a float as a fraction:

```
>>> x = 3.14159
>>> x.as_integer_ratio()
(3537115888337719, 1125899906842624)
```

Since the ratio is exact, it can be used to losslessly recreate the original value:

```
>>> x == 3537115888337719 / 1125899906842624
True
```

The `float.hex()` method expresses a float in hexadecimal (base 16), again giving the exact value stored by your computer:

```
>>> x.hex()
'0x1.921f9f01b866ep+1'
```

This precise hexadecimal representation can be used to reconstruct the float value exactly:

```
>>> x == float.fromhex('0x1.921f9f01b866ep+1')
True
```

Since the representation is exact, it is useful for reliably porting values across different versions of Python (platform independence) and exchanging data with other languages that support the same format (such as Java and C99).

Another helpful tool is the `math.fsum()` function which helps mitigate loss-of-precision during summation. It tracks “lost digits” as values are added onto a running total. That can make a difference in overall accuracy so that the errors do not accumulate to the point where they affect the final total:

```
>>> sum([0.1] * 10) == 1.0
```

```
False
>>> math.fsum([0.1] * 10) == 1.0
True
```

## 15.1. Representation Error

This section explains the “0.1” example in detail, and shows how you can perform an exact analysis of cases like this yourself. Basic familiarity with binary floating-point representation is assumed.

*Representation error* refers to the fact that some (most, actually) decimal fractions cannot be represented exactly as binary (base 2) fractions. This is the chief reason why Python (or Perl, C, C++, Java, Fortran, and many others) often won’t display the exact decimal number you expect.

Why is that?  $1/10$  is not exactly representable as a binary fraction. Since at least 2000, almost all machines use IEEE 754 binary floating-point arithmetic, and almost all platforms map Python floats to IEEE 754 binary64 “double precision” values. IEEE 754 binary64 values contain 53 bits of precision, so on input the computer strives to convert 0.1 to the closest fraction it can of the form  $J/2^N$  where  $J$  is an integer containing exactly 53 bits.

Rewriting

$$1 / 10 \approx J / (2^N)$$

as

$$J \approx 2^N / 10$$

and recalling that  $J$  has exactly 53 bits (is  $\geq 2^{52}$  but  $< 2^{53}$ ), the best value for  $N$  is 56:

```
>>> 2**52 <= 2**56 // 10 < 2**53
True
```

That is, 56 is the only value for  $N$  that leaves  $J$  with exactly 53 bits. The best possible value for  $J$  is then that quotient rounded:

```
>>> q, r = divmod(2**56, 10)
```

```
>>> r
6
```

Since the remainder is more than half of 10, the best approximation is obtained by rounding up:

```
>>> q+1
7205759403792794
```

Therefore the best possible approximation to  $1/10$  in IEEE 754 double precision is:

```
7205759403792794 / 2 ** 56
```

Dividing both the numerator and denominator by two reduces the fraction to:

```
3602879701896397 / 2 ** 55
```

Note that since we rounded up, this is actually a little bit larger than  $1/10$ ; if we had not rounded up, the quotient would have been a little bit smaller than  $1/10$ . But in no case can it be *exactly*  $1/10$ !

So the computer never “sees”  $1/10$ : what it sees is the exact fraction given above, the best IEEE 754 double approximation it can get:

```
>>> 0.1 * 2 ** 55
3602879701896397.0
```

If we multiply that fraction by  $10^{55}$ , we can see the value out to 55 decimal digits:

```
>>> 3602879701896397 * 10 ** 55 // 2 ** 55
10000000000000000055511151231257827021181583404541015625
```

meaning that the exact number stored in the computer is equal to the decimal value

0.10000000000000000055511151231257827021181583404541015625.

Instead of displaying the full decimal value, many languages (including older versions of Python), round the result to 17 significant digits:

```
>>> format(0.1, '.17f')
'0.100000000000000001'
```

The **fractions** and **decimal** modules make these calculations easy:

```
>>> from decimal import Decimal
>>> from fractions import Fraction
```

```
>>> Fraction.from_float(0.1)
Fraction(3602879701896397, 36028797018963968)
```

```
>>> (0.1).as_integer_ratio()
(3602879701896397, 36028797018963968)
```

```
>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000005551115123125782702118158340')
```

```
>>> format(Decimal.from_float(0.1), '.17f')
'0.100000000000000001'
```

# 16. Appendix

## 16.1. Interactive Mode

### 16.1.1. Error Handling

When an error occurs, the interpreter prints an error message and a stack trace. In interactive mode, it then returns to the primary prompt; when input came from a file, it exits with a nonzero exit status after printing the stack trace. (Exceptions handled by an `except` clause in a `try` statement are not errors in this context.) Some errors are unconditionally fatal and cause an exit with a nonzero exit; this applies to internal inconsistencies and some cases of running out of memory. All error messages are written to the standard error stream; normal output from executed commands is written to standard output.

Typing the interrupt character (usually `Control-C` or `Delete`) to the primary or secondary prompt cancels the input and returns to the primary prompt. <sup>1</sup> Typing an interrupt while a command is executing raises the `KeyboardInterrupt` exception, which may be handled by a `try` statement.

### 16.1.2. Executable Python Scripts

On BSD'ish Unix systems, Python scripts can be made directly executable, like shell scripts, by putting the line

```
#!/usr/bin/env python3.5
```

(assuming that the interpreter is on the user's **PATH**) at the beginning of the script and giving the file an executable mode. The `#!` must be the first two characters of the file. On some platforms, this first line must end with a Unix-style line ending (`'\n'`), not a Windows (`'\r\n'`) line ending. Note that the hash, or pound, character, `'#'`, is used to start a comment in Python.

The script can be given an executable mode, or permission, using the **chmod** command.

```
$ chmod +x myscript.py
```

On Windows systems, there is no notion of an “executable mode”. The Python installer automatically associates `.py` files with `python.exe` so that a double-click on a Python file will run it as a script. The extension can also be `.pyw`, in that case, the console window that normally appears is suppressed.

### 16.1.3. The Interactive Startup File

When you use Python interactively, it is frequently handy to have some standard commands executed every time the interpreter is started. You can do this by setting an environment variable named **PYTHONSTARTUP** to the name of a file containing your start-up commands. This is similar to the `.profile` feature of the Unix shells.

This file is only read in interactive sessions, not when Python reads commands from a script, and not when `/dev/tty` is given as the explicit source of commands (which otherwise behaves like an interactive session). It is executed in the same namespace where interactive commands are executed, so that objects that it defines or imports can be used without qualification in the interactive session. You can also change the prompts `sys.ps1` and `sys.ps2` in this file.

If you want to read an additional start-up file from the current directory, you can program this in the global start-up file using code like `if os.path.isfile('.pythonrc.py'):`  
`exec(open('.pythonrc.py').read())`. If you want to use the startup file in a script, you must do this explicitly in the script:

```
import os
filename = os.environ.get('PYTHONSTARTUP')
if filename and os.path.isfile(filename):
    with open(filename) as fobj:
        startup_file = fobj.read()
```

```
exec(startup_file)
```

### 16.1.4. The Customization Modules

Python provides two hooks to let you customize it:

**sitecustomize** and **usercustomize**. To see how it works, you need first to find the location of your user site-packages directory. Start Python and run this code:

```
>>> import site
>>> site.getusersitepackages()
'/home/user/.local/lib/python3.5/site-packages'
```

Now you can create a file named `usercustomize.py` in that directory and put anything you want in it. It will affect every invocation of Python, unless it is started with the `-s` option to disable the automatic import.

**sitecustomize** works in the same way, but is typically created by an administrator of the computer in the global site-packages directory, and is imported before **usercustomize**. See the documentation of the `site` module for more details.

### Footnotes

1

A problem with the GNU Readline package may prevent this.

# Python Setup and Usage

This part of the documentation is devoted to general information on the setup of the Python environment on different platforms, the invocation of the interpreter and things that make working with Python easier.

# 1. Command line and environment

The CPython interpreter scans the command line and the environment for various settings.

**CPython implementation detail:** Other implementations' command line schemes may differ. See [Alternate Implementations](#) for further resources.

## 1.1. Command line

When invoking Python, you may specify any of these options:

```
python [-bBdEhiIOqsSuvVWx?] [-c command | -m module-name]
```

The most common use case is, of course, a simple invocation of a script:

```
python myscript.py
```

### 1.1.1. Interface options

The interpreter interface resembles that of the UNIX shell, but provides some additional methods of invocation:

- When called with standard input connected to a tty device, it prompts for commands and executes them until an EOF (an end-of-file character, you can produce that with `Ctrl-D` on UNIX or `Ctrl-Z`, `Enter` on Windows) is read.
- When called with a file name argument or with a file as standard input, it reads and executes a script from that file.
- When called with a directory name argument, it reads and executes an appropriately named script from that directory.
- When called with `-c command`, it executes the Python

statement(s) given as *command*. Here *command* may contain multiple statements separated by newlines. Leading whitespace is significant in Python statements!

- When called with `-m module-name`, the given module is located on the Python module path and executed as a script.

In non-interactive mode, the entire input is parsed before it is executed.

An interface option terminates the list of options consumed by the interpreter, all consecutive arguments will end up in `sys.argv` – note that the first element, subscript zero (`sys.argv[0]`), is a string reflecting the program's source.

`-c <command>`

Execute the Python code in *command*. *command* can be one or more statements separated by newlines, with significant leading whitespace as in normal module code.

If this option is given, the first element of `sys.argv` will be `"-c"` and the current directory will be added to the start of `sys.path` (allowing modules in that directory to be imported as top level modules).

Raises an `auditing event` `cpython.run_command` with argument `command`.

`-m <module-name>`

Search `sys.path` for the named module and execute its contents as the `__main__` module.

Since the argument is a *module* name, you must not give a file extension (`.py`). The module name should be a valid absolute Python module name, but the implementation may not always enforce this (e.g. it may allow you to use a name that includes a hyphen).

Package names (including namespace packages) are also permitted. When a package name is supplied instead of a normal module, the interpreter will execute `<pkg>.__main__` as the main module. This behaviour is

deliberately similar to the handling of directories and zipfiles that are passed to the interpreter as the script argument.

### Note

This option cannot be used with built-in modules and extension modules written in C, since they do not have Python module files. However, it can still be used for precompiled modules, even if the original source file is not available.

If this option is given, the first element of `sys.argv` will be the full path to the module file (while the module file is being located, the first element will be set to `"-m"`). As with the `-c` option, the current directory will be added to the start of `sys.path`.

`-I` option can be used to run the script in isolated mode where `sys.path` contains neither the current directory nor the user's site-packages directory. All `PYTHON*` environment variables are ignored, too.

Many standard library modules contain code that is invoked on their execution as a script. An example is the `timeit` module:

```
python -m timeit -s 'setup here' 'benchmarked code'
python -m timeit -h # for details
```

Raises an `auditing event` `cpython.run_module` with argument `module-name`.

### See also

#### `runpy.run_module()`

Equivalent functionality directly available to Python code

**PEP 338** [<https://peps.python.org/pep-0338/>] – Executing modules as scripts

*Changed in version 3.1:* Supply the package name to run a `__main__` submodule.

*Changed in version 3.4:* namespace packages are also supported

-

Read commands from standard input (`sys.stdin`). If standard input is a terminal, `-i` is implied.

If this option is given, the first element of `sys.argv` will be `"-"` and the current directory will be added to the start of `sys.path`.

Raises an `auditing event` `cpython.run_stdin` with no arguments.

< script >

Execute the Python code contained in *script*, which must be a filesystem path (absolute or relative) referring to either a Python file, a directory containing a `__main__.py` file, or a zipfile containing a `__main__.py` file.

If this option is given, the first element of `sys.argv` will be the script name as given on the command line.

If the script name refers directly to a Python file, the directory containing that file is added to the start of `sys.path`, and the file is executed as the `__main__` module.

If the script name refers to a directory or zipfile, the script name is added to the start of `sys.path` and the `__main__.py` file in that location is executed as the `__main__` module.

`-I` option can be used to run the script in isolated mode where `sys.path` contains neither the script's directory nor the user's site-packages directory. All `PYTHON*` environment variables are ignored, too.

Raises an [auditing event](#) `cpython.run_file` with argument `filename`.

### See also

[runpy.run\\_path\(\)](#)

Equivalent functionality directly available to Python code

If no interface option is given, `-i` is implied, `sys.argv[0]` is an empty string ("") and the current directory will be added to the start of [sys.path](#). Also, tab-completion and history editing is automatically enabled, if available on your platform (see [Readline configuration](#)).

### See also

[Invoking the Interpreter](#)

*Changed in version 3.4:* Automatic enabling of tab-completion and history editing.

## 1.1.2. Generic options

`-?`

`-h`

`--help`

Print a short description of all command line options and corresponding environment variables and exit.

`--help-env`

Print a short description of Python-specific environment variables and exit.

*New in version 3.11.*

`--help-xoptions`

Print a description of implementation-specific **-X** options and exit.

*New in version 3.11.*

**--help-all**

Print complete usage information and exit.

*New in version 3.11.*

**-V**

**--version**

Print the Python version number and exit. Example output could be:

```
Python 3.8.0b2+
```

When given twice, print more information about the build, like:

```
Python 3.8.0b2+ (3.8:0c076caaa8, Apr 20 2019, 21:55  
[GCC 6.2.0 20161005]
```

*New in version 3.6:* The **-VV** option.

### 1.1.3. Miscellaneous options

**-b**

Issue a warning when comparing **bytes** or **bytearray** with **str** or **bytes** with **int**. Issue an error when the option is given twice (**-bb**).

*Changed in version 3.5:* Affects comparisons of **bytes** with **int**.

**-B**

If given, Python won't try to write `.pyc` files on the import of source modules. See also **PYTHONDONTWRITEBYTECODE**.

`--check-hash-based-pycs default|always|never`

Control the validation behavior of hash-based `.pyc` files. See [Cached bytecode invalidation](#). When set to `default`, checked and unchecked hash-based bytecode cache files are validated according to their default semantics. When set to `always`, all hash-based `.pyc` files, whether checked or unchecked, are validated against their corresponding source file. When set to `never`, hash-based `.pyc` files are not validated against their corresponding source files.

The semantics of timestamp-based `.pyc` files are unaffected by this option.

`-d`

Turn on parser debugging output (for expert only, depending on compilation options). See also [PYTHONDEBUG](#).

`-E`

Ignore all **PYTHON\*** environment variables, e.g. [PYTHONPATH](#) and [PYTHONHOME](#), that might be set.

See also the `-P` and `-I` (isolated) options.

`-i`

When a script is passed as first argument or the `-c` option is used, enter interactive mode after executing the script or the command, even when `sys.stdin` does not appear to be a terminal. The [PYTHONSTARTUP](#) file is not read.

This can be useful to inspect global variables or a stack trace when a script raises an exception. See also [PYTHONINSPECT](#).

`-I`

Run Python in isolated mode. This also implies `-E`, `-P` and `-s` options.

In isolated mode `sys.path` contains neither the script's directory nor the user's site-packages directory. All **PYTHON\*** environment variables are ignored, too. Further restrictions

may be imposed to prevent the user from injecting malicious code.

*New in version 3.4.*

**-O**

Remove assert statements and any code conditional on the value of `__debug__`. Augment the filename for compiled (bytecode) files by adding `.opt-1` before the `.pyc` extension (see [PEP 488](https://peps.python.org/pep-0488/) [https://peps.python.org/pep-0488/]). See also [PYTHONOPTIMIZE](#).

*Changed in version 3.5:* Modify `.pyc` filenames according to [PEP 488](https://peps.python.org/pep-0488/) [https://peps.python.org/pep-0488/].

**-OO**

Do **-O** and also discard docstrings. Augment the filename for compiled (bytecode) files by adding `.opt-2` before the `.pyc` extension (see [PEP 488](https://peps.python.org/pep-0488/) [https://peps.python.org/pep-0488/]).

*Changed in version 3.5:* Modify `.pyc` filenames according to [PEP 488](https://peps.python.org/pep-0488/) [https://peps.python.org/pep-0488/].

**-P**

Don't prepend a potentially unsafe path to `sys.path`:

- `python -m module` command line: Don't prepend the current working directory.
- `python script.py` command line: Don't prepend the script's directory. If it's a symbolic link, resolve symbolic links.
- `python -c code` and `python (REPL)` command lines: Don't prepend an empty string, which means the current working directory.

See also the [PYTHONSAFEPATH](#) environment variable, and **-E** and **-I** (isolated) options.

*New in version 3.11.*

-q

Don't display the copyright and version messages even in interactive mode.

*New in version 3.2.*

-R

Turn on hash randomization. This option only has an effect if the **PYTHONHASHSEED** environment variable is set to 0, since hash randomization is enabled by default.

On previous versions of Python, this option turns on hash randomization, so that the `__hash__()` values of str and bytes objects are “salted” with an unpredictable random value. Although they remain constant within an individual Python process, they are not predictable between repeated invocations of Python.

Hash randomization is intended to provide protection against a denial-of-service caused by carefully chosen inputs that exploit the worst case performance of a dict construction,  $O(n^2)$  complexity. See <http://ocert.org/advisories/ocert-2011-003.html> for details.

**PYTHONHASHSEED** allows you to set a fixed value for the hash seed secret.

*Changed in version 3.7:* The option is no longer ignored.

*New in version 3.2.3.*

-S

Don't add the **user site-packages directory** to `sys.path`.

**See also**

**PEP 370** [<https://peps.python.org/pep-0370/>] – Per user site-packages directory

-S

Disable the import of the module `site` and the site-dependent manipulations of `sys.path` that it entails. Also disable these manipulations if `site` is explicitly imported later (call `site.main()` if you want them to be triggered).

-u

Force the stdout and stderr streams to be unbuffered. This option has no effect on the stdin stream.

See also `PYTHONUNBUFFERED`.

*Changed in version 3.7:* The text layer of the stdout and stderr streams now is unbuffered.

-v

Print a message each time a module is initialized, showing the place (filename or built-in module) from which it is loaded. When given twice (`-vv`), print a message for each file that is checked for when searching for a module. Also provides information on module cleanup at exit.

*Changed in version 3.10:* The `site` module reports the site-specific paths and `.pth` files being processed.

See also `PYTHONVERBOSE`.

-W arg

Warning control. Python's warning machinery by default prints warning messages to `sys.stderr`.

The simplest settings apply a particular action unconditionally to all warnings emitted by a process (even those that are otherwise ignored by default):

```
-Wdefault    # Warn once per call location
-Werror      # Convert to exceptions
-Walways     # Warn every time
-Wmodule     # Warn once per calling module
```

```
-Wonce      # Warn once per Python process
-Wignore    # Never warn
```

The action names can be abbreviated as desired and the interpreter will resolve them to the appropriate action name. For example, `-Wi` is the same as `-Wignore`.

The full form of argument is:

```
action:message:category:module:lineno
```

Empty fields match all values; trailing empty fields may be omitted. For example `-W ignore::DeprecationWarning` ignores all `DeprecationWarning` warnings.

The *action* field is as explained above but only applies to warnings that match the remaining fields.

The *message* field must match the whole warning message; this match is case-insensitive.

The *category* field matches the warning category (ex: `DeprecationWarning`). This must be a class name; the match test whether the actual warning category of the message is a subclass of the specified warning category.

The *module* field matches the (fully qualified) module name; this match is case-sensitive.

The *lineno* field matches the line number, where zero matches all line numbers and is thus equivalent to an omitted line number.

Multiple `-W` options can be given; when a warning matches more than one option, the action for the last matching option is performed. Invalid `-W` options are ignored (though, a warning message is printed about invalid options when the first warning is issued).

Warnings can also be controlled using the `PYTHONWARNINGS` environment variable and from within a Python program using the `warnings` module. For example, the

`warnings.filterwarnings()` function can be used to use a regular expression on the warning message.

See [The Warnings Filter](#) and [Describing Warning Filters](#) for more details.

-X

Skip the first line of the source, allowing use of non-Unix forms of `#!cmd`. This is intended for a DOS specific hack only.

-X

Reserved for various implementation-specific options. CPython currently defines the following possible values:

- `-X faulthandler` to enable [faulthandler](#). See also [PYTHONFAULTHANDLER](#).
- `-X showrefcount` to output the total reference count and number of used memory blocks when the program finishes or after each statement in the interactive interpreter. This only works on [debug builds](#).
- `-X tracemalloc` to start tracing Python memory allocations using the [tracemalloc](#) module. By default, only the most recent frame is stored in a traceback of a trace. Use `-X tracemalloc=NFRAME` to start tracing with a traceback limit of *NFRAME* frames. See [tracemalloc.start\(\)](#) and [PYTHONTRACEMALLOC](#) for more information.
- `-X int_max_str_digits` configures the [integer string conversion length limitation](#). See also [PYTHONINTMAXSTRDIGITS](#).
- `-X importtime` to show how long each import takes. It shows module name, cumulative time (including nested imports) and self time (excluding nested imports). Note that its output may be broken in multi-threaded application. Typical usage is `python3 -X importtime -c 'import asyncio'`. See also [PYTHONPROFILEIMPORTTIME](#).
- `-X dev`: enable [Python Development Mode](#), introducing additional runtime checks that are too

expensive to be enabled by default.

- `-X utf8` enables the [Python UTF-8 Mode](#). `-X utf8=0` explicitly disables [Python UTF-8 Mode](#) (even when it would otherwise activate automatically). See also [PYTHONUTF8](#).
- `-X pycache_prefix=PATH` enables writing `.pyc` files to a parallel tree rooted at the given directory instead of to the code tree. See also [PYTHONPYCACHEPREFIX](#).
- `-X warn_default_encoding` issues a [EncodingWarning](#) when the locale-specific default encoding is used for opening files. See also [PYTHONWARNDEFAULTENCODING](#).
- `-X no_debug_ranges` disables the inclusion of the tables mapping extra location information (end line, start column offset and end column offset) to every instruction in code objects. This is useful when smaller code objects and pyc files are desired as well as suppressing the extra visual location indicators when the interpreter displays tracebacks. See also [PYTHONNODEBUGRANGES](#).
- `-X frozen_modules` determines whether or not frozen modules are ignored by the import machinery. A value of “on” means they get imported and “off” means they are ignored. The default is “on” if this is an installed Python (the normal case). If it’s under development (running from the source tree) then the default is “off”. Note that the “`importlib_bootstrap`” and “`importlib_bootstrap_external`” frozen modules are always used, even if this flag is set to “off”.

It also allows passing arbitrary values and retrieving them through the [sys.\\_xoptions](#) dictionary.

*Changed in version 3.2:* The `-X` option was added.

*New in version 3.3:* The `-X faulthandler` option.

*New in version 3.4:* The `-X showrefcount` and `-X tracemalloc` options.

*New in version 3.6:* The `-X showalloccount` option.

*New in version 3.7:* The `-X importtime`, `-X dev` and `-X utf8` options.

*New in version 3.8:* The `-X pycache_prefix` option. The `-X dev` option now logs `close()` exceptions in `io.IOBase` destructor.

*Changed in version 3.9:* Using `-X dev` option, check *encoding* and *errors* arguments on string encoding and decoding operations.

The `-X showalloccount` option has been removed.

*New in version 3.10:* The `-X warn_default_encoding` option.

*Deprecated since version 3.9, removed in version 3.10:* The `-X oldparser` option.

*New in version 3.11:* The `-X no_debug_ranges` option.

*New in version 3.11:* The `-X frozen_modules` option.

*New in version 3.11:* The `-X int_max_str_digits` option.

### 1.1.4. Options you shouldn't use

`-J`

Reserved for use by [Jython](https://www.jython.org/) [https://www.jython.org/].

## 1.2. Environment variables

These environment variables influence Python's behavior, they are processed before the command-line switches other than `-E` or `-I`. It is customary that command-line switches override environmental variables where there is a conflict.

`PYTHONHOME`

Change the location of the standard Python libraries. By default, the libraries are searched in `prefix/lib/pythonversion` and `exec_prefix/lib/pythonversion`, where `prefix` and `exec_prefix` are installation-dependent directories, both defaulting to `/usr/local`.

When `PYTHONHOME` is set to a single directory, its value replaces both `prefix` and `exec_prefix`. To specify different values for these, set `PYTHONHOME` to `prefix:exec_prefix`.

## PYTHONPATH

Augment the default search path for module files. The format is the same as the shell's `PATH`: one or more directory pathnames separated by `os.pathsep` (e.g. colons on Unix or semicolons on Windows). Non-existent directories are silently ignored.

In addition to normal directories, individual `PYTHONPATH` entries may refer to zipfiles containing pure Python modules (in either source or compiled form). Extension modules cannot be imported from zipfiles.

The default search path is installation dependent, but generally begins with `prefix/lib/pythonversion` (see `PYTHONHOME` above). It is *always* appended to `PYTHONPATH`.

An additional directory will be inserted in the search path in front of `PYTHONPATH` as described above under [Interface options](#). The search path can be manipulated from within a Python program as the variable `sys.path`.

## PYTHONSAFEPATH

If this is set to a non-empty string, don't prepend a potentially unsafe path to `sys.path`: see the `-P` option for details.

*New in version 3.11.*

## PYTHONPLATLIBDIR

If this is set to a non-empty string, it overrides the `sys.platlibdir` value.

*New in version 3.9.*

## PYTHONSTARTUP

If this is the name of a readable file, the Python commands in that file are executed before the first prompt is displayed in interactive mode. The file is executed in the same namespace where interactive commands are executed so that objects defined or imported in it can be used without qualification in the interactive session. You can also change the prompts `sys.ps1` and `sys.ps2` and the hook `sys.__interactivehook__` in this file.

Raises an `auditing event` `cpython.run_startup` with the filename as the argument when called on startup.

## PYTHONOPTIMIZE

If this is set to a non-empty string it is equivalent to specifying the `-O` option. If set to an integer, it is equivalent to specifying `-O` multiple times.

## PYTHONBREAKPOINT

If this is set, it names a callable using dotted-path notation. The module containing the callable will be imported and then the callable will be run by the default implementation of `sys.breakpointhook()` which itself is called by built-in `breakpoint()`. If not set, or set to the empty string, it is equivalent to the value `"pdb.set_trace"`. Setting this to the string `"0"` causes the default implementation of `sys.breakpointhook()` to do nothing but return immediately.

*New in version 3.7.*

## PYTHONDEBUG

If this is set to a non-empty string it is equivalent to specifying the `-d` option. If set to an integer, it is equivalent

to specifying `-d` multiple times.

#### PYTHONINSPECT

If this is set to a non-empty string it is equivalent to specifying the `-i` option.

This variable can also be modified by Python code using `os.environ` to force inspect mode on program termination.

#### PYTHONUNBUFFERED

If this is set to a non-empty string it is equivalent to specifying the `-u` option.

#### PYTHONVERBOSE

If this is set to a non-empty string it is equivalent to specifying the `-v` option. If set to an integer, it is equivalent to specifying `-v` multiple times.

#### PYTHONCASEOK

If this is set, Python ignores case in `import` statements. This only works on Windows and macOS.

#### PYTHONDONTWRITEBYTECODE

If this is set to a non-empty string, Python won't try to write `.pyc` files on the import of source modules. This is equivalent to specifying the `-B` option.

#### PYTHONPYCACHEPREFIX

If this is set, Python will write `.pyc` files in a mirror directory tree at this path, instead of in `__pycache__` directories within the source tree. This is equivalent to specifying the `-X pycache_prefix=PATH` option.

*New in version 3.8.*

#### PYTHONHASHSEED

If this variable is not set or set to `random`, a random value is used to seed the hashes of str and bytes objects.

If `PYTHONHASHSEED` is set to an integer value, it is used as a fixed seed for generating the `hash()` of the types covered by the hash randomization.

Its purpose is to allow repeatable hashing, such as for selftests for the interpreter itself, or to allow a cluster of python processes to share hash values.

The integer must be a decimal number in the range [0,4294967295]. Specifying the value 0 will disable hash randomization.

*New in version 3.2.3.*

## PYTHONINTMAXSTRDIGITS

If this variable is set to an integer, it is used to configure the interpreter's global [integer string conversion length limitation](#).

*New in version 3.11.*

## PYTHONIOENCODING

If this is set before running the interpreter, it overrides the encoding used for `stdin/stdout/stderr`, in the syntax `encodingname:errorhandler`. Both the `encodingname` and the `:errorhandler` parts are optional and have the same meaning as in `str.encode()`.

For `stderr`, the `:errorhandler` part is ignored; the handler will always be `'backslashreplace'`.

*Changed in version 3.4:* The `encodingname` part is now optional.

*Changed in version 3.6:* On Windows, the encoding specified by this variable is ignored for interactive console buffers unless `PYTHONLEGACYWINDOWSSTDIO` is also specified. Files and pipes redirected through the standard streams are not affected.

## PYTHONNOUSERSITE

If this is set, Python won't add the **user site-packages directory** to **sys.path**.

### See also

**PEP 370** [<https://peps.python.org/pep-0370/>] – Per user site-packages directory

## PYTHONUSERBASE

Defines the **user base directory**, which is used to compute the path of the **user site-packages directory** and **Distutils installation paths** for `python setup.py install --user`.

### See also

**PEP 370** [<https://peps.python.org/pep-0370/>] – Per user site-packages directory

## PYTHONEXECUTABLE

If this environment variable is set, `sys.argv[0]` will be set to its value instead of the value got through the C runtime. Only works on macOS.

## PYTHONWARNINGS

This is equivalent to the **-W** option. If set to a comma separated string, it is equivalent to specifying **-W** multiple times, with filters later in the list taking precedence over those earlier in the list.

The simplest settings apply a particular action unconditionally to all warnings emitted by a process (even those that are otherwise ignored by default):

```
PYTHONWARNINGS=default    # Warn once per call locati
PYTHONWARNINGS=error      # Convert to exceptions
```

```
PYTHONWARNINGS=always      # Warn every time
PYTHONWARNINGS=module      # Warn once per calling mod
PYTHONWARNINGS=once        # Warn once per Python proc
PYTHONWARNINGS=ignore      # Never warn
```

See [The Warnings Filter](#) and [Describing Warning Filters](#) for more details.

## PYTHONFAULTHANDLER

If this environment variable is set to a non-empty string, [`faulthandler.enable\(\)`](#) is called at startup: install a handler for **SIGSEGV**, **SIGFPE**, **SIGABRT**, **SIGBUS** and **SIGILL** signals to dump the Python traceback. This is equivalent to **-X** `faulthandler` option.

*New in version 3.3.*

## PYTHONTRACEMALLOC

If this environment variable is set to a non-empty string, start tracing Python memory allocations using the [`tracemalloc`](#) module. The value of the variable is the maximum number of frames stored in a traceback of a trace. For example, `PYTHONTRACEMALLOC=1` stores only the most recent frame. See the [`tracemalloc.start\(\)`](#) function for more information. This is equivalent to setting the **-X** `tracemalloc` option.

*New in version 3.4.*

## PYTHONPROFILEIMPORTTIME

If this environment variable is set to a non-empty string, Python will show how long each import takes. This is equivalent to setting the **-X** `importtime` option.

*New in version 3.7.*

## PYTHONASYNCIODEBUG

If this environment variable is set to a non-empty string, enable the [`debug mode`](#) of the [`asyncio`](#) module.

*New in version 3.4.*

## PYTHONMALLOC

Set the Python memory allocators and/or install debug hooks.

Set the family of memory allocators used by Python:

- `default`: use the [default memory allocators](#).
- `malloc`: use the `malloc()` function of the C library for all domains (`PYMEM_DOMAIN_RAW`, `PYMEM_DOMAIN_MEM`, `PYMEM_DOMAIN_OBJ`).
- `pymalloc`: use the [pymalloc allocator](#) for `PYMEM_DOMAIN_MEM` and `PYMEM_DOMAIN_OBJ` domains and use the `malloc()` function for the `PYMEM_DOMAIN_RAW` domain.

Install [debug hooks](#):

- `debug`: install debug hooks on top of the [default memory allocators](#).
- `malloc_debug`: same as `malloc` but also install debug hooks.
- `pymalloc_debug`: same as `pymalloc` but also install debug hooks.

*Changed in version 3.7:* Added the "default" allocator.

*New in version 3.6.*

## PYTHONMALLOCSSTATS

If set to a non-empty string, Python will print statistics of the [pymalloc memory allocator](#) every time a new pymalloc object arena is created, and on shutdown.

This variable is ignored if the `PYTHONMALLOC` environment variable is used to force the `malloc()` allocator of the C library, or if Python is configured without `pymalloc` support.

*Changed in version 3.6:* This variable can now also be used on Python compiled in release mode. It now has no effect if set

to an empty string.

## PYTHONLEGACYWINDOWSFSENCODING

If set to a non-empty string, the default [filesystem encoding and error handler](#) mode will revert to their pre-3.6 values of ‘mbcs’ and ‘replace’, respectively. Otherwise, the new defaults ‘utf-8’ and ‘surrogatepass’ are used.

This may also be enabled at runtime with [`sys.\_enablelegacywindowsfsencoding\(\)`](#).

[Availability](#): Windows.

*New in version 3.6*: See [PEP 529](#) [<https://peps.python.org/pep-0529/>] for more details.

## PYTHONLEGACYWINDOWSSTDIO

If set to a non-empty string, does not use the new console reader and writer. This means that Unicode characters will be encoded according to the active console code page, rather than using utf-8.

This variable is ignored if the standard streams are redirected (to files or pipes) rather than referring to console buffers.

[Availability](#): Windows.

*New in version 3.6*.

## PYTHONCOERCECLOCALE

If set to the value `0`, causes the main Python command line application to skip coercing the legacy ASCII-based C and POSIX locales to a more capable UTF-8 based alternative.

If this variable is *not* set (or is set to a value other than `0`), the `LC_ALL` locale override environment variable is also not set, and the current locale reported for the `LC_CTYPE` category is either the default C locale, or else the explicitly ASCII-based POSIX locale, then the Python CLI will attempt to configure the following locales for the `LC_CTYPE` category

in the order listed before loading the interpreter runtime:

- `C.UTF-8`
- `C.utf8`
- `UTF-8`

If setting one of these locale categories succeeds, then the `LC_CTYPE` environment variable will also be set accordingly in the current process environment before the Python runtime is initialized. This ensures that in addition to being seen by both the interpreter itself and other locale-aware components running in the same process (such as the GNU `readline` library), the updated setting is also seen in subprocesses (regardless of whether or not those processes are running a Python interpreter), as well as in operations that query the environment rather than the current C locale (such as Python's own `locale.getdefaultlocale()`).

Configuring one of these locales (either explicitly or via the above implicit locale coercion) automatically enables the surrogateescape [error handler](#) for `sys.stdin` and `sys.stdout` (`sys.stderr` continues to use `backslashreplace` as it does in any other locale). This stream handling behavior can be overridden using `PYTHONIOENCODING` as usual.

For debugging purposes, setting `PYTHONCOERCECLOCALE=warn` will cause Python to emit warning messages on `stderr` if either the locale coercion activates, or else if a locale that *would* have triggered coercion is still active when the Python runtime is initialized.

Also note that even when locale coercion is disabled, or when it fails to find a suitable target locale, `PYTHONUTF8` will still activate by default in legacy ASCII-based locales. Both features must be disabled in order to force the interpreter to use `ASCII` instead of `UTF-8` for system interfaces.

[Availability](#): Unix.

*New in version 3.7:* See [PEP 538](#) [<https://peps.python.org/pep-0538/>]

for more details.

## PYTHONDEVMODE

If this environment variable is set to a non-empty string, enable [Python Development Mode](#), introducing additional runtime checks that are too expensive to be enabled by default. This is equivalent to setting the `-X dev` option.

*New in version 3.7.*

## PYTHONUTF8

If set to `1`, enable the [Python UTF-8 Mode](#).

If set to `0`, disable the [Python UTF-8 Mode](#).

Setting any other non-empty string causes an error during interpreter initialisation.

*New in version 3.7.*

## PYTHONWARNDEFAULTENCODING

If this environment variable is set to a non-empty string, issue a [EncodingWarning](#) when the locale-specific default encoding is used.

See [Opt-in EncodingWarning](#) for details.

*New in version 3.10.*

## PYTHONNODEBUGRANGES

If this variable is set, it disables the inclusion of the tables mapping extra location information (end line, start column offset and end column offset) to every instruction in code objects. This is useful when smaller code objects and pyc files are desired as well as suppressing the extra visual location indicators when the interpreter displays tracebacks.

*New in version 3.11.*

### 1.2.1. Debug-mode variables

#### PYTHONTHREADDEBUG

If set, Python will print threading debug info into stdout.

Need a [debug build of Python](#).

*Deprecated since version 3.10, will be removed in version 3.12.*

#### PYTHONDUMPREFS

If set, Python will dump objects and reference counts still alive after shutting down the interpreter.

Need Python configured with the `--with-trace-refs` build option.

#### PYTHONDUMPREFSFILE = FILENAME

If set, Python will dump objects and reference counts still alive after shutting down the interpreter into a file called *FILENAME*.

Need Python configured with the `--with-trace-refs` build option.

*New in version 3.11.*

## 2. Using Python on Unix platforms

### 2.1. Getting and installing the latest version of Python

#### 2.1.1. On Linux

Python comes preinstalled on most Linux distributions, and is available as a package on all others. However there are certain features you might want to use that are not available on your distro's package. You can easily compile the latest version of Python from source.

In the event that Python doesn't come preinstalled and isn't in the repositories as well, you can easily make packages for your own distro. Have a look at the following links:

**See also**

<https://www.debian.org/doc/manuals/maint-guide/first.en.html>

for Debian users

<https://en.opensuse.org/Portal:Packaging>

for OpenSuse users

[https://docs-old.fedoraproject.org/en-US/Fedora\\_Draft\\_Documentation/0.1/html/RPM\\_Guide/ch-creating-rpms.html](https://docs-old.fedoraproject.org/en-US/Fedora_Draft_Documentation/0.1/html/RPM_Guide/ch-creating-rpms.html)

for Fedora users

<http://www.slackbook.org/html/package-management-making-packages.html>

for Slackware users

### 2.1.2. On FreeBSD and OpenBSD

- FreeBSD users, to add the package use:

```
pkg install python3
```

- OpenBSD users, to add the package use:

```
pkg_add -r python
```

```
pkg_add ftp://ftp.openbsd.org/pub/OpenBSD/4.2/packa
```

For example i386 users get the 2.5.1 version of Python using:

```
pkg_add ftp://ftp.openbsd.org/pub/OpenBSD/4.2/packa
```

### 2.1.3. On OpenSolaris

You can get Python from [OpenCSW](https://www.opensw.org/) [https://www.opensw.org/]. Various versions of Python are available and can be installed with e.g.

```
pkgutil -i python27.
```

## 2.2. Building Python

If you want to compile CPython yourself, first thing you should do is get the [source](https://www.python.org/downloads/source/) [https://www.python.org/downloads/source/]. You can download either the latest release's source or just grab a fresh [clone](https://devguide.python.org/setup/#get-the-source-code) [https://devguide.python.org/setup/#get-the-source-code]. (If you want to contribute patches, you will need a clone.)

The build process consists of the usual commands:

```
./configure  
make  
make install
```

[Configuration options](#) and caveats for specific Unix platforms are extensively documented in the [README.rst](https://github.com/python/) [https://github.com/python/

cpython/tree/3.11/README.rst] file in the root of the Python source tree.

## Warning

make install can overwrite or masquerade the python3 binary. make altinstall is therefore recommended instead of make install since it only installs `exec_prefix/bin/pythonversion`.

## 2.3. Python-related paths and files

These are subject to difference depending on local installation conventions; `prefix` and `exec_prefix` are installation-dependent and should be interpreted as for GNU software; they may be the same.

For example, on most Linux systems, the default for both is `/usr`.

### ~~Make directory~~

---

~~Recommended location of the interpreter.~~

---

~~Recommended locations of the directories containing the standard modules.~~

---

~~Recommended locations of the directories containing the include files needed for developing Python extensions and embedding the interpreter.~~

---

## 2.4. Miscellaneous

To easily use Python scripts on Unix, you need to make them executable, e.g. with

```
$ chmod +x script
```

and put an appropriate Shebang line at the top of the script. A good choice is usually

```
#!/usr/bin/env python3
```

which searches for the Python interpreter in the whole **PATH**.

However, some Unices may not have the **env** command, so you may need to hardcode `/usr/bin/python3` as the interpreter path.

To use shell commands in your Python scripts, look at the **subprocess** module.

## 2.5. Custom OpenSSL

1. To use your vendor's OpenSSL configuration and system trust store, locate the directory with `openssl.cnf` file or symlink in `/etc`. On most distribution the file is either in `/etc/ssl` or `/etc/pki/tls`. The directory should also contain a `cert.pem` file and/or a `certs` directory.

```
$ find /etc/ -name openssl.cnf -printf "%h\n"
/etc/ssl
```

2. Download, build, and install OpenSSL. Make sure you use `install_sw` and not `install`. The `install_sw` target does not override `openssl.cnf`.

```
$ curl -O https://www.openssl.org/source/openssl-VERSION
$ tar xzf openssl-VERSION
$ pushd openssl-VERSION
$ ./config \
    --prefix=/usr/local/custom-openssl \
    --libdir=lib \
    --openssldir=/etc/ssl
$ make -j1 depend
$ make -j8
$ make install_sw
$ popd
```

3. Build Python with custom OpenSSL (see the configure `--with-openssl` and `--with-openssl-rpath` options)

```
$ pushd python-3.x.x
$ ./configure -C \
    --with-openssl=/usr/local/custom-openssl \
    --with-openssl-rpath=auto \
```

```
    --prefix=/usr/local/python-3.x.x  
$ make -j8  
$ make altinstall
```

## **Note**

Patch releases of OpenSSL have a backwards compatible ABI. You don't need to recompile Python to update OpenSSL. It's sufficient to replace the custom OpenSSL installation with a newer version.

## 3. Configure Python

### 3.1. Configure Options

List all `./configure` script options using:

```
./configure --help
```

See also the `Misc/SpecialBuilds.txt` in the Python source distribution.

#### 3.1.1. General Options

`--enable-loadable-sqlite-extensions`

Support loadable extensions in the `_sqlite` extension module (default is no).

See the

`sqlite3.Connection.enable_load_extension()` method of the `sqlite3` module.

*New in version 3.6.*

`--disable-ipv6`

Disable IPv6 support (enabled by default if supported), see the `socket` module.

`--enable-big-digits=[15|30]`

Define the size in bits of Python `int` digits: 15 or 30 bits.

By default, the digit size is 30.

Define the `PYLONG_BITS_IN_DIGIT` to 15 or 30.

See `sys.int_info.bits_per_digit`.

`--with-cxx-main`

`--with-cxx-main=COMPILER`

Compile the Python `main()` function and link Python executable with C++ compiler: `$CXX`, or *COMPILER* if specified.

`--with-suffix=SUFFIX`

Set the Python executable suffix to *SUFFIX*.

The default suffix is `.exe` on Windows and macOS (python.exe executable), `.js` on Emscripten node, `.html` on Emscripten browser, `.wasm` on WASI, and an empty string on other platforms (python executable).

*Changed in version 3.11:* The default suffix on WASM platform is one of `.js`, `.html` or `.wasm`.

`--with-tzpath=<list of absolute paths separated by pathsep>`

Select the default time zone search path for [`zoneinfo.TZPATH`](#). See the [Compile-time configuration](#) of the [`zoneinfo`](#) module.

Default: `/usr/share/zoneinfo:/usr/lib/zoneinfo:/usr/share/lib/zoneinfo:/etc/zoneinfo`.

See [`os.pathsep`](#) path separator.

*New in version 3.9.*

`--without-decimal-contextvar`

Build the `_decimal` extension module using a thread-local context rather than a coroutine-local context (default), see the [`decimal`](#) module.

See [`decimal.HAVE\_CONTEXTVAR`](#) and the [`contextvars`](#) module.

*New in version 3.9.*

`--with-dbmliborder = <list of backend names>`

Override order to check db backends for the `dbm` module

A valid value is a colon (:) separated string with the backend names:

- `ndbm`;
- `gdbm`;
- `bdb`.

`--without-c-locale-coercion`

Disable C locale coercion to a UTF-8 based locale (enabled by default).

Don't define the `PY_COERCE_C_LOCALE` macro.

See `PYTHONCOERCECLOCALE` and the `PEP 538` [<https://peps.python.org/pep-0538/>].

`--with-platlibdir = DIRNAME`

Python library directory name (default is `lib`).

Fedora and SuSE use `lib64` on 64-bit platforms.

See `sys.platlibdir`.

*New in version 3.9.*

`--with-wheel-pkg-dir = PATH`

Directory of wheel packages used by the `ensurepip` module (none by default).

Some Linux distribution packaging policies recommend against bundling dependencies. For example, Fedora installs wheel packages in the `/usr/share/python-wheels/` directory and don't install the `ensurepip._bundled` package.

*New in version 3.10.*

`--with-pkg-config = [check|yes|no]`

Whether configure should use **pkg-config** to detect build dependencies.

- `check` (default): **pkg-config** is optional
- `yes`: **pkg-config** is mandatory
- `no`: configure does not use **pkg-config** even when present

*New in version 3.11.*

`--enable-pystats`

Turn on internal statistics gathering.

The statistics will be dumped to a arbitrary (probably unique) file in `/tmp/py_stats/`, or `C:\temp\py_stats\` on Windows.

Use `Tools/scripts/summarize_stats.py` to read the stats.

*New in version 3.11.*

### 3.1.2. WebAssembly Options

`--with-emscripten-target = [browser|node]`

Set build flavor for `wasm32-emscripten`.

- `browser` (default): preload minimal stdlib, default MEMFS.
- `node`: NODERAWFS and pthread support.

*New in version 3.11.*

`--enable-wasm-dynamic-linking`

Turn on dynamic linking support for WASM.

Dynamic linking enables `dlopen`. File size of the executable increases due to limited dead code elimination and additional features.

*New in version 3.11.*

`--enable-wasm-pthreads`

Turn on pthreads support for WASM.

*New in version 3.11.*

### 3.1.3. Install Options

`--prefix=PREFIX`

Install architecture-independent files in PREFIX. On Unix, it defaults to `/usr/local`.

This value can be retrieved at runtime using `sys.prefix`.

As an example, one can use `--prefix="$HOME/.local/"` to install a Python in its home directory.

`--exec-prefix=EPREFIX`

Install architecture-dependent files in EPREFIX, defaults to `--prefix`.

This value can be retrieved at runtime using `sys.exec_prefix`.

`--disable-test-modules`

Don't build nor install test modules, like the `test` package or the `_testcapi` extension module (built and installed by default).

*New in version 3.10.*

`--with-ensurepip=[upgrade|install|no]`

Select the `ensurepip` command run on Python installation:

- `upgrade (default):` run `python -m ensurepip --altinstall --upgrade command`.
- `install:` run `python -m ensurepip --altinstall command`;

- no: don't run ensurepip;

*New in version 3.6.*

### 3.1.4. Performance options

Configuring Python using `--enable-optimizations --with-lto` (PGO + LTO) is recommended for best performance.

`--enable-optimizations`

Enable Profile Guided Optimization (PGO) using **PROFILE\_TASK** (disabled by default).

The C compiler Clang requires `llvm-profdata` program for PGO. On macOS, GCC also requires it: GCC is just an alias to Clang on macOS.

Disable also semantic interposition in libpython if `--enable-shared` and GCC is used: add `-fno-semantic-interposition` to the compiler and linker flags.

*New in version 3.6.*

*Changed in version 3.10:* Use `-fno-semantic-interposition` on GCC.

**PROFILE\_TASK**

Environment variable used in the Makefile: Python command line arguments for the PGO generation task.

Default: `-m test --pgo --timeout=$(TESTTIMEOUT)`.

*New in version 3.8.*

`--with-lto=[full|thin|no|yes]`

Enable Link Time Optimization (LTO) in any build (disabled by default).

The C compiler Clang requires `llvm-ar` for LTO (`ar` on macOS), as well as an LTO-aware linker (`ld.gold` or `lld`).

*New in version 3.6.*

*New in version 3.11:* To use ThinLTO feature, use `--with-lto=thin` on Clang.

`--with-computed-gotos`

Enable computed gotos in evaluation loop (enabled by default on supported compilers).

`--without-pymalloc`

Disable the specialized Python memory allocator [pymalloc](#) (enabled by default).

See also [PYTHONMALLOC](#) environment variable.

`--without-doc-strings`

Disable static documentation strings to reduce the memory footprint (enabled by default). Documentation strings defined in Python are not affected.

Don't define the `WITH_DOC_STRINGS` macro.

See the `PyDoc_STRVAR()` macro.

`--enable-profiling`

Enable C-level code profiling with `gprof` (disabled by default).

### 3.1.5. Python Debug Build

A debug build is Python built with the `--with-pydebug` configure option.

Effects of a debug build:

- Display all warnings by default: the list of default warning filters is empty in the [warnings](#) module.
- Add `d` to [sys.abiflags](#).
- Add `sys.gettotalrefcount()` function.

- Add `-X showrefcount` command line option.
  - Add `PYTHONTHREADDEBUG` environment variable.
  - Add support for the `__lltrace__` variable: enable low-level tracing in the bytecode evaluation loop if the variable is defined.
  - Install [debug hooks on memory allocators](#) to detect buffer overflow and other memory errors.
  - Define `Py_DEBUG` and `Py_REF_DEBUG` macros.
  - Add runtime checks: code surrounded by `#ifdef Py_DEBUG` and `#endif`. Enable `assert(...)` and `_PyObject_ASSERT(...)` assertions: don't set the `NDEBUG` macro (see also the `--with-assertions` configure option).
- Main runtime checks:

- Add sanity checks on the function arguments.
- Unicode and int objects are created with their memory filled with a pattern to detect usage of uninitialized objects.
- Ensure that functions which can clear or replace the current exception are not called with an exception raised.
- Check that deallocator functions don't change the current exception.
- The garbage collector (`gc.collect()` function) runs some basic checks on objects consistency.
- The `Py_SAFE_DOWNCAST()` macro checks for integer underflow and overflow when downcasting from wide types to narrow types.

See also the [Python Development Mode](#) and the `--with-trace-refs` configure option.

*Changed in version 3.8:* Release builds and debug builds are now ABI compatible: defining the `Py_DEBUG` macro no longer implies the `Py_TRACE_REFS` macro (see the `--with-trace-refs` option), which introduces the only ABI incompatibility.

### 3.1.6. Debug options

`--with-pydebug`

[Build Python in debug mode](#): define the `Py_DEBUG` macro

(disabled by default).

#### `--with-trace-refs`

Enable tracing references for debugging purpose (disabled by default).

Effects:

- Define the `Py_TRACE_REFS` macro.
- Add `sys.getobjects()` function.
- Add `PYTHONDUMPREFS` environment variable.

This build is not ABI compatible with release build (default build) or debug build (`Py_DEBUG` and `Py_REF_DEBUG` macros).

*New in version 3.8.*

#### `--with-assertions`

Build with C assertions enabled (default is no):

`assert(...);` and `_PyObject_ASSERT(...);`.

If set, the `NDEBUG` macro is not defined in the **OPT** compiler variable.

See also the `--with-pydebug` option (**debug build**) which also enables assertions.

*New in version 3.6.*

#### `--with-valgrind`

Enable Valgrind support (default is no).

#### `--with-dtrace`

Enable DTrace support (default is no).

See [Instrumenting CPython with DTrace and SystemTap](#).

*New in version 3.6.*

`--with-address-sanitizer`

Enable AddressSanitizer memory error detector, `asan` (default is no).

*New in version 3.6.*

`--with-memory-sanitizer`

Enable MemorySanitizer allocation error detector, `msan` (default is no).

*New in version 3.6.*

`--with-undefined-behavior-sanitizer`

Enable UndefinedBehaviorSanitizer undefined behaviour detector, `ubsan` (default is no).

*New in version 3.6.*

### 3.1.7. Linker options

`--enable-shared`

Enable building a shared Python library: `libpython` (default is no).

`--without-static-libpython`

Do not build `libpythonMAJOR.MINOR.a` and do not install `python.o` (built and enabled by default).

*New in version 3.10.*

### 3.1.8. Libraries options

`--with-libs='lib1 ...'`

Link against additional libraries (default is no).

`--with-system-expat`

Build the **pyexpat** module using an installed `expat` library (default is no).

`--with-system-ffi`

Build the `_ctypes` extension module using an installed `ffi` library, see the `ctypes` module (default is system-dependent).

`--with-system-libmpdec`

Build the `_decimal` extension module using an installed `mpdec` library, see the `decimal` module (default is no).

*New in version 3.3.*

`--with-readline=editline`

Use `editline` library for backend of the `readline` module.

Define the `WITH_EDITLINE` macro.

*New in version 3.10.*

`--without-readline`

Don't build the `readline` module (built by default).

Don't define the `HAVE_LIBREADLINE` macro.

*New in version 3.10.*

`--with-libm=STRING`

Override `libm` math library to *STRING* (default is system-dependent).

`--with-libc=STRING`

Override `libc` C library to *STRING* (default is system-dependent).

`--with-openssl=DIR`

Root of the OpenSSL directory.

*New in version 3.7.*

`--with-openssl-rpath = [no|auto|DIR]`

Set runtime library directory (rpath) for OpenSSL libraries:

- `no` (default): don't set rpath;
- `auto`: auto-detect rpath from `--with-openssl` and `pkg-config`;
- `DIR`: set an explicit rpath.

*New in version 3.10.*

### 3.1.9. Security Options

`--with-hash-algorithm = [fnv|siphhash13|siphhash24]`

Select hash algorithm for use in `Python/pyhash.c`:

- `siphhash13` (default);
- `siphhash24`;
- `fnv`.

*New in version 3.4.*

*New in version 3.11:* `siphhash13` is added and it is the new default.

`--with-builtin-hashlib-`

`hashes = md5,sha1,sha256,sha512,sha3,blake2`

Built-in hash modules:

- `md5`;
- `sha1`;
- `sha256`;
- `sha512`;
- `sha3` (with `shake`);
- `blake2`.

*New in version 3.9.*

`--with-ssl-default-suites = [python|openssl|STRING]`

Override the OpenSSL default cipher suites string:

- `python` (default): use Python's preferred selection;
- `openssl`: leave OpenSSL's defaults untouched;
- *STRING*: use a custom string

See the `ssl` module.

*New in version 3.7.*

*Changed in version 3.10:* The settings `python` and *STRING* also set TLS 1.2 as minimum protocol version.

### 3.1.10. macOS Options

See `Mac/README.rst`.

`--enable-universalsdk`

`--enable-universalsdk = SDKDIR`

Create a universal binary build. *SDKDIR* specifies which macOS SDK should be used to perform the build (default is `no`).

`--enable-framework`

`--enable-framework = INSTALLDIR`

Create a `Python.framework` rather than a traditional Unix install. Optional *INSTALLDIR* specifies the installation path (default is `no`).

`--with-universal-archs = ARCH`

Specify the kind of universal binary that should be created. This option is only valid when `--enable-universalsdk` is set.

Options:

- `universal2`;
- `32-bit`;
- `64-bit`;
- `3-way`;

- intel;
- intel-32;
- intel-64;
- all.

**--with-framework-name = FRAMEWORK**

Specify the name for the python framework on macOS only valid when **--enable-framework** is set (default: Python).

### 3.1.11. Cross Compiling Options

Cross compiling, also known as cross building, can be used to build Python for another CPU architecture or platform. Cross compiling requires a Python interpreter for the build platform. The version of the build Python must match the version of the cross compiled host Python.

**--build = BUILD**

configure for building on BUILD, usually guessed by **config.guess**.

**--host = HOST**

cross-compile to build programs to run on HOST (target platform)

**--with-build-python = path/to/python**

path to build `python` binary for cross compiling

*New in version 3.11.*

**CONFIG\_SITE = file**

An environment variable that points to a file with configure overrides.

Example *config.site* file:

```
# config.site-aarch64
ac_cv_buggy_getaddrinfo=no
```

```
ac_cv_file__dev_ptmx=yes
ac_cv_file__dev_ptc=no
```

Cross compiling example:

```
CONFIG_SITE=config.site-aarch64 ../configure \
--build=x86_64-pc-linux-gnu \
--host=aarch64-unknown-linux-gnu \
--with-build-python=../x86_64/python
```

## 3.2. Python Build System

### 3.2.1. Main files of the build system

- `configure.ac` => `configure`;
- `Makefile.pre.in` => `Makefile` (created by `configure`);
- `pyconfig.h` (created by `configure`);
- `Modules/Setup`: C extensions built by the Makefile using `Module/makesetup` shell script;
- `setup.py`: C extensions built using the `distutils` module.

### 3.2.2. Main build steps

- C files (`.c`) are built as object files (`.o`).
- A static `libpython` library (`.a`) is created from objects files.
- `python.o` and the static `libpython` library are linked into the final `python` program.
- C extensions are built by the Makefile (see `Modules/Setup`) and `python setup.py build`.

### 3.2.3. Main Makefile targets

- `make`: Build Python with the standard library.
- `make platform::` build the `python` program, but don't build the standard library extension modules.
- `make profile-opt`: build Python using Profile Guided Optimization (PGO). You can use the `configure --enable-optimizations` option to make this the default target of the

- make **command** (make all or just make).
- make **buildbottest**: Build Python and run the Python test suite, the same way than buildbots test Python. Set **TESTTIMEOUT** variable (in seconds) to change the test timeout (1200 by default: 20 minutes).
- make **install**: Build and install Python.
- make **regen-all**: Regenerate (almost) all generated files; make **regen-stdlib-module-names** and **autoconf** must be run separately for the remaining generated files.
- make **clean**: Remove built files.
- make **distclean**: Same than make clean, but remove also files created by the configure script.

### 3.2.4. C extensions

Some C extensions are built as built-in modules, like the `sys` module. They are built with the `Py_BUILD_CORE_BUILTIN` macro defined. Built-in modules have no `__file__` attribute:

```
>>> import sys
>>> sys
<module 'sys' (built-in)>
>>> sys.__file__
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: module 'sys' has no attribute '__file__'
```

Other C extensions are built as dynamic libraries, like the `_asyncio` module. They are built with the `Py_BUILD_CORE_MODULE` macro defined. Example on Linux x86-64:

```
>>> import _asyncio
>>> _asyncio
<module '_asyncio' from '/usr/lib64/python3.9/lib-dynload/_asyncio.cpython-39-x86_64-linux-gnu.so'>
>>> _asyncio.__file__
'/usr/lib64/python3.9/lib-dynload/_asyncio.cpython-39-x86_64-linux-gnu.so'
```

`Modules/Setup` is used to generate Makefile targets to build C extensions. At the beginning of the files, C extensions are built as

built-in modules. Extensions defined after the `*shared*` marker are built as dynamic libraries.

The `setup.py` script only builds C extensions as shared libraries using the `distutils` module.

The `PyAPI_FUNC()`, `PyAPI_API()` and `PyMODINIT_FUNC()` macros of `Include/pyport.h` are defined differently depending if the `Py_BUILD_CORE_MODULE` macro is defined:

- Use `Py_EXPORTED_SYMBOL` if the `Py_BUILD_CORE_MODULE` is defined
- Use `Py_IMPORTED_SYMBOL` otherwise.

If the `Py_BUILD_CORE_BUILTIN` macro is used by mistake on a C extension built as a shared library, its `PyInit_xxx()` function is not exported, causing an `ImportError` on import.

## 3.3. Compiler and linker flags

Options set by the `./configure` script and environment variables and used by `Makefile`.

### 3.3.1. Preprocessor flags

`CONFIGURE_CPPFLAGS`

Value of `CPPFLAGS` variable passed to the `./configure` script.

*New in version 3.6.*

`CPPFLAGS`

(Objective) C/C++ preprocessor flags, e.g. `-I<include dir>` if you have headers in a nonstandard directory `<include dir>`.

Both `CPPFLAGS` and `LDFLAGS` need to contain the shell's value for `setup.py` to be able to build extension modules using the directories specified in the environment variables.

## BASECPPFLAGS

*New in version 3.4.*

## PY\_CPPFLAGS

Extra preprocessor flags added for building the interpreter object files.

Default: `$(BASECPPFLAGS) -I. -I$(srcdir)/Include $(CONFIGURE_CPPFLAGS) $(CPPFLAGS)`.

*New in version 3.2.*

## 3.3.2. Compiler flags

### CC

C compiler command.

Example: `gcc -pthread`.

### MAINCC

C compiler command used to build the `main()` function of programs like `python`.

Variable set by the `--with-cxx-main` option of the configure script.

Default: `$(CC)`.

### CXX

C++ compiler command.

Used if the `--with-cxx-main` option is used.

Example: `g++ -pthread`.

### CFLAGS

C compiler flags.

### CFLAGS\_NODIST

**CFLAGS\_NODIST** is used for building the interpreter and stdlib C extensions. Use it when a compiler flag should *not* be part of the distutils **CFLAGS** once Python is installed ([bpo-21121](https://bugs.python.org/issue?@action=redirect&bpo=21121) [https://bugs.python.org/issue?@action=redirect&bpo=21121]).

In particular, **CFLAGS** should not contain:

- the compiler flag `-I` (for setting the search path for include files). The `-I` flags are processed from left to right, and any flags in **CFLAGS** would take precedence over user- and package-supplied `-I` flags.
- hardening flags such as `-Werror` because distributions cannot control whether packages installed by users conform to such heightened standards.

*New in version 3.5.*

## EXTRA\_CFLAGS

Extra C compiler flags.

## CONFIGURE\_CFLAGS

Value of **CFLAGS** variable passed to the `./configure` script.

*New in version 3.2.*

## CONFIGURE\_CFLAGS\_NODIST

Value of **CFLAGS\_NODIST** variable passed to the `./configure` script.

*New in version 3.5.*

## BASECFLAGS

Base compiler flags.

## OPT

Optimization flags.

## CFLAGS\_ALIASING

Strict or non-strict aliasing flags used to compile `Python/dtoa.c`.

*New in version 3.7.*

## CCSHARED

Compiler flags used to build a shared library.

For example, `-fPIC` is used on Linux and on BSD.

## CFLAGSFORSHARED

Extra C flags added for building the interpreter object files.

Default: `$(CCSHARED)` when `--enable-shared` is used, or an empty string otherwise.

## PY\_CFLAGS

Default: `$(BASECFLAGS) $(OPT) $(CONFIGURE_CFLAGS) $(CFLAGS) $(EXTRA_CFLAGS)`.

## PY\_CFLAGS\_NODIST

Default: `$(CONFIGURE_CFLAGS_NODIST) $(CFLAGS_NODIST) -I$(srcdir)/Include/internal`.

*New in version 3.5.*

## PY\_STDMODULE\_CFLAGS

C flags used for building the interpreter object files.

Default: `$(PY_CFLAGS) $(PY_CFLAGS_NODIST) $(PY_CPPFLAGS) $(CFLAGSFORSHARED)`.

*New in version 3.7.*

## PY\_CORE\_CFLAGS

Default: `$(PY_STDMODULE_CFLAGS) -DPY_BUILD_CORE`.

*New in version 3.2.*

## PY\_BUILTIN\_MODULE\_CFLAGS

Compiler flags to build a standard library extension module as a built-in module, like the `posix` module.

Default: `$(PY_STDMODULE_CFLAGS) -DPY_BUILD_CORE_BUILTIN`.

*New in version 3.8.*

## PURIFY

Purify command. Purify is a memory debugger program.

Default: empty string (not used).

### 3.3.3. Linker flags

## LINKCC

Linker command used to build programs like `python` and `_testembed`.

Default: `$(PURIFY) $(MAINCC)`.

## CONFIGURE\_LDFLAGS

Value of `LD_FLAGS` variable passed to the `./configure` script.

Avoid assigning `CFLAGS`, `LD_FLAGS`, etc. so users can use them on the command line to append to these values without stomping the pre-set values.

*New in version 3.2.*

## LD\_FLAGS\_NODIST

`LD_FLAGS_NODIST` is used in the same manner as `CFLAGS_NODIST`. Use it when a linker flag should *not* be part of the distutils `LD_FLAGS` once Python is installed ([bpo-35257](https://bugs.python.org/issue?@action=redirect&bpo=35257) [<https://bugs.python.org/issue?@action=redirect&bpo=35257>]).

In particular, `LD_FLAGS` should not contain:

- the compiler flag `-L` (for setting the search path for libraries). The `-L` flags are processed from left to right, and any flags in `LDFLAGS` would take precedence over user- and package-supplied `-L` flags.

## CONFIGURE\_LDFLAGS\_NODIST

Value of `LDFLAGS_NODIST` variable passed to the `./configure` script.

*New in version 3.8.*

## LDFLAGS

Linker flags, e.g. `-L<lib dir>` if you have libraries in a nonstandard directory `<lib dir>`.

Both `CPPFLAGS` and `LDFLAGS` need to contain the shell's value for `setup.py` to be able to build extension modules using the directories specified in the environment variables.

## LIBS

Linker flags to pass libraries to the linker when linking the Python executable.

Example: `-lrt`.

## LD\_SHARED

Command to build a shared library.

Default: `@LD_SHARED@ $(PY_LDFLAGS)`.

## BLD\_SHARED

Command to build `libpython` shared library.

Default: `@BLD_SHARED@ $(PY_CORE_LDFLAGS)`.

## PY\_LDFLAGS

Default: `$(CONFIGURE_LDFLAGS) $(LDFLAGS)`.

## PY\_LDFLAGS\_NODIST

Default: `$(CONFIGURE_LDFLAGS_NODIST)`  
`$(LDFLAGS_NODIST)`.

*New in version 3.8.*

## PY\_CORE\_LDFLAGS

Linker flags used for building the interpreter object files.

*New in version 3.8.*

## 4. Using Python on Windows

This document aims to give an overview of Windows-specific behaviour you should know about when using Python on Microsoft Windows.

Unlike most Unix systems and services, Windows does not include a system supported installation of Python. To make Python available, the CPython team has compiled Windows installers (MSI packages) with every [release](https://www.python.org/download/releases/) [https://www.python.org/download/releases/] for many years. These installers are primarily intended to add a per-user installation of Python, with the core interpreter and library being used by a single user. The installer is also able to install for all users of a single machine, and a separate ZIP file is available for application-local distributions.

As specified in [PEP 11](https://peps.python.org/pep-0011/) [https://peps.python.org/pep-0011/], a Python release only supports a Windows platform while Microsoft considers the platform under extended support. This means that Python 3.11 supports Windows 8.1 and newer. If you require Windows 7 support, please install Python 3.8.

There are a number of different installers available for Windows, each with certain benefits and downsides.

[The full installer](#) contains all components and is the best option for developers using Python for any kind of project.

[The Microsoft Store package](#) is a simple installation of Python that is suitable for running scripts and packages, and using IDLE or other development environments. It requires Windows 10 and above, but can be safely installed without corrupting other programs. It also provides many convenient commands for launching Python and its tools.

[The nuget.org packages](#) are lightweight installations intended for continuous integration systems. It can be used to build Python packages or run scripts, but is not updateable and has no user interface tools.

[The embeddable package](#) is a minimal package of Python suitable for embedding into a larger application.

## 4.1. The full installer

### 4.1.1. Installation steps

Four Python 3.11 installers are available for download - two each for the 32-bit and 64-bit versions of the interpreter. The *web installer* is a small initial download, and it will automatically download the required components as necessary. The *offline installer* includes the components necessary for a default installation and only requires an internet connection for optional features. See [Installing Without Downloading](#) for other ways to avoid downloading during installation.

After starting the installer, one of two options may be selected:

If you select “Install Now”:

- You will *not* need to be an administrator (unless a system update for the C Runtime Library is required or you install

the [Python Launcher for Windows](#) for all users)

- Python will be installed into your user directory
- The [Python Launcher for Windows](#) will be installed according to the option at the bottom of the first page
- The standard library, test suite, launcher and pip will be installed
- If selected, the install directory will be added to your **PATH**
- Shortcuts will only be visible for the current user

Selecting “Customize installation” will allow you to select the features to install, the installation location and other options or post-install actions. To install debugging symbols or binaries, you will need to use this option.

To perform an all-users installation, you should select “Customize installation”. In this case:

- You may be required to provide administrative credentials or approval
- Python will be installed into the Program Files directory
- The [Python Launcher for Windows](#) will be installed into the Windows directory
- Optional features may be selected during installation
- The standard library can be pre-compiled to bytecode
- If selected, the install directory will be added to the system **PATH**
- Shortcuts are available for all users

#### 4.1.2. Removing the MAX\_PATH Limitation

Windows historically has limited path lengths to 260 characters. This meant that paths longer than this would not resolve and errors would result.

In the latest versions of Windows, this limitation can be expanded to approximately 32,000 characters. Your administrator will need to activate the “Enable Win32 long paths” group policy, or set LongPathsEnabled to 1 in the registry key  
HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet  
\Control\FileSystem.

This allows the `open()` function, the `os` module and most other path functionality to accept and return paths longer than 260 characters.

After changing the above option, no further configuration is required.

*Changed in version 3.6:* Support for long paths was enabled in Python.

### 4.1.3. Installing Without UI

All of the options available in the installer UI can also be specified from the command line, allowing scripted installers to replicate an installation on many machines without user interaction. These options may also be set without suppressing the UI in order to change some of the defaults.

To completely hide the installer UI and install Python silently, pass the `/quiet` option. To skip past the user interaction but still display progress and errors, pass the `/passive` option. The `/uninstall` option may be passed to immediately begin removing Python - no confirmation prompt will be displayed.

All other options are passed as `name=value`, where the value is usually `0` to disable a feature, `1` to enable a feature, or a path. The full list of available options is shown below.

<b>Description</b>
<b>DefaultAllUsers</b> System-wide installation.
<b>TargetBasedOnDefaultAllUsers</b> Target-based modification of DefaultAllUsers
<b>DefaultInstallTargetDirectoryForAllUserInstalls</b> Default install target directory for all user installs (x86) %\Python X.Y
<b>DefaultInstallTargetDirectoryForJustForMeInstalls</b> Default install target directory for just-for-me installs XY or %LocalAppData%\Programs\Python\PythonXY-32 or %LocalAppData%\Programs\Python\PythonXY-64
<b>DefaultCustomTargetInstallDirectoryDisplayedInTheUI</b> Default custom target install directory displayed in the UI
<b>AssociateFileAssociations</b> if the launcher is also installed.
<b>CompileAll</b> .py files to .pyc.
<b>DependHash</b> Path and Scripts directories to <b>PATH</b> and add .PY to <b>PATHEXT</b>

Append Path and Scripts directories to **PATH** and add .PY to

**PATHEXT**

Shortcuts for the interpreter, documentation and IDLE if installed.

Install Python manual

Install debug binaries

Install developer headers and libraries. Omitting this may lead to an unusable installation.

Install python.exe and related files. Omitting this may lead to an unusable installation.

Install [launcher for Windows](#).

Install the launcher for all users. Also requires

Include\_launcher to be set to 1

Install standard library and extension modules. Omitting this may lead to an unusable installation.

Install pip and setuptools

Install debugging symbols (\*.pdb)

Install IDLE support and IDLE

Install standard library test suite

Install utility scripts

Only install the launcher. This will override most other options.

Disable install UI

SimpleInstallDescription display when the simplified install UI is used.

For example, to silently install a default, system-wide Python installation, you could use the following command (from an elevated command prompt):

```
python-3.9.0.exe /quiet InstallAllUsers=1 PrependPath=1
```

To allow users to easily install a personal copy of Python without the test suite, you could provide a shortcut with the following command. This will display a simplified initial page and disallow customization:

```
python-3.9.0.exe InstallAllUsers=0 Include_launcher=0 In  
SimpleInstall=1 SimpleInstallDescription="Just for m
```

(Note that omitting the launcher also omits file associations, and is only recommended for per-user installs when there is also a system-

wide installation that included the launcher.)

The options listed above can also be provided in a file named `unattend.xml` alongside the executable. This file specifies a list of options and values. When a value is provided as an attribute, it will be converted to a number if possible. Values provided as element text are always left as strings. This example file sets the same options as the previous example:

```
<Options>
  <Option Name="InstallAllUsers" Value="no" />
  <Option Name="Include_launcher" Value="0" />
  <Option Name="Include_test" Value="no" />
  <Option Name="SimpleInstall" Value="yes" />
  <Option Name="SimpleInstallDescription">Just for me,
</Options>
```

#### 4.1.4. Installing Without Downloading

As some features of Python are not included in the initial installer download, selecting those features may require an internet connection. To avoid this need, all possible components may be downloaded on-demand to create a complete *layout* that will no longer require an internet connection regardless of the selected features. Note that this download may be bigger than required, but where a large number of installations are going to be performed it is very useful to have a locally cached copy.

Execute the following command from Command Prompt to download all possible required files. Remember to substitute `python-3.9.0.exe` for the actual name of your installer, and to create layouts in their own directories to avoid collisions between files with the same name.

```
python-3.9.0.exe /layout [optional target directory]
```

You may also specify the `/quiet` option to hide the progress display.

#### 4.1.5. Modifying an install

Once Python has been installed, you can add or remove features through the Programs and Features tool that is part of Windows. Select the Python entry and choose “Uninstall/Change” to open the installer in maintenance mode.

“Modify” allows you to add or remove features by modifying the checkboxes - unchanged checkboxes will not install or remove anything. Some options cannot be changed in this mode, such as the install directory; to modify these, you will need to remove and then reinstall Python completely.

“Repair” will verify all the files that should be installed using the current settings and replace any that have been removed or modified.

“Uninstall” will remove Python entirely, with the exception of the [Python Launcher for Windows](#), which has its own entry in Programs and Features.

## 4.2. The Microsoft Store package

*New in version 3.7.2.*

The Microsoft Store package is an easily installable Python interpreter that is intended mainly for interactive use, for example, by students.

To install the package, ensure you have the latest Windows 10 updates and search the Microsoft Store app for “Python 3.11”. Ensure that the app you select is published by the Python Software Foundation, and install it.

### Warning

Python will always be available for free on the Microsoft Store. If you are asked to pay for it, you have not selected the correct package.

After installation, Python may be launched by finding it in Start. Alternatively, it will be available from any Command Prompt or

PowerShell session by typing `python`. Further, `pip` and `IDLE` may be used by typing `pip` or `idle`. `IDLE` can also be found in Start.

All three commands are also available with version number suffixes, for example, as `python3.exe` and `python3.x.exe` as well as `python.exe` (where `3.x` is the specific version you want to launch, such as `3.11`). Open “Manage App Execution Aliases” through Start to select which version of Python is associated with each command. It is recommended to make sure that `pip` and `idle` are consistent with whichever version of `python` is selected.

Virtual environments can be created with `python -m venv` and activated and used as normal.

If you have installed another version of Python and added it to your `PATH` variable, it will be available as `python.exe` rather than the one from the Microsoft Store. To access the new installation, use `python3.exe` or `python3.x.exe`.

The `py.exe` launcher will detect this Python installation, but will prefer installations from the traditional installer.

To remove Python, open Settings and use Apps and Features, or else find Python in Start and right-click to select Uninstall. Uninstalling will remove all packages you installed directly into this Python installation, but will not remove any virtual environments

## 4.2.1. Known issues

### 4.2.1.1. Redirection of local data, registry, and temporary paths

Because of restrictions on Microsoft Store apps, Python scripts may not have full write access to shared locations such as **TEMP** and the registry. Instead, it will write to a private copy. If your scripts must modify the shared locations, you will need to install the full installer.

At runtime, Python will use a private copy of well-known Windows folders and the registry. For example, if the environment variable **%APPDATA%** is `c:\Users\<user>\AppData\`, then when writing

to `C:\Users\<user>\AppData\Local` will write to `C:\Users\<user>\AppData\Local\Packages\PythonSoftwareFoundation.Python.3.8_qbz5n2kfra8p0\Local\Local\`.

When reading files, Windows will return the file from the private folder, or if that does not exist, the real Windows directory. For example reading `C:\Windows\System32` returns the contents of `C:\Windows\System32` plus the contents of `C:\Program Files\WindowsApps\package_name\VFS\SystemX86`.

You can find the real path of any existing file using `os.path.realpath()`:

```
>>> import os
>>> test_file = 'C:\\Users\\example\\AppData\\Local\\tes
>>> os.path.realpath(test_file)
'C:\\Users\\example\\AppData\\Local\\Packages\\PythonSof
```

When writing to the Windows Registry, the following behaviors exist:

- Reading from `HKLM\\Software` is allowed and results are merged with the `registry.dat` file in the package.
- Writing to `HKLM\\Software` is not allowed if the corresponding key/value exists, i.e. modifying existing keys.
- Writing to `HKLM\\Software` is allowed as long as a corresponding key/value does not exist in the package and the user has the correct access permissions.

For more detail on the technical basis for these limitations, please consult Microsoft's documentation on packaged full-trust apps, currently available at [docs.microsoft.com/en-us/windows/msix/desktop/desktop-to-uwp-behind-the-scenes](https://docs.microsoft.com/en-us/windows/msix/desktop/desktop-to-uwp-behind-the-scenes) [https://docs.microsoft.com/en-us/windows/msix/desktop/desktop-to-uwp-behind-the-scenes]

## 4.3. The nuget.org packages

*New in version 3.5.2.*

The nuget.org package is a reduced size Python environment

intended for use on continuous integration and build systems that do not have a system-wide install of Python. While nuget is “the package manager for .NET”, it also works perfectly fine for packages containing build-time tools.

Visit [nuget.org](https://www.nuget.org/) [https://www.nuget.org/] for the most up-to-date information on using nuget. What follows is a summary that is sufficient for Python developers.

The `nuget.exe` command line tool may be downloaded directly from <https://aka.ms/nugetclidl>, for example, using curl or PowerShell. With the tool, the latest version of Python for 64-bit or 32-bit machines is installed using:

```
nuget.exe install python -ExcludeVersion -OutputDirectory .
nuget.exe install pythonx86 -ExcludeVersion -OutputDirectory .
```

To select a particular version, add a `-Version 3.x.y`. The output directory may be changed from `.`, and the package will be installed into a subdirectory. By default, the subdirectory is named the same as the package, and without the `-ExcludeVersion` option this name will include the specific version installed. Inside the subdirectory is a `tools` directory that contains the Python installation:

```
# Without -ExcludeVersion
> .\python.3.5.2\tools\python.exe -V
Python 3.5.2
```

```
# With -ExcludeVersion
> .\python\tools\python.exe -V
Python 3.5.2
```

In general, nuget packages are not upgradeable, and newer versions should be installed side-by-side and referenced using the full path. Alternatively, delete the package directory manually and install it again. Many CI systems will do this automatically if they do not preserve files between builds.

Alongside the `tools` directory is a `build\native` directory. This contains a MSBuild properties file `python.props` that can be used

in a C++ project to reference the Python install. Including the settings will automatically use the headers and import libraries in your build.

The package information pages on nuget.org are [www.nuget.org/packages/python](https://www.nuget.org/packages/python) [https://www.nuget.org/packages/python] for the 64-bit version and [www.nuget.org/packages/pythonx86](https://www.nuget.org/packages/pythonx86) [https://www.nuget.org/packages/pythonx86] for the 32-bit version.

## 4.4. The embeddable package

*New in version 3.5.*

The embedded distribution is a ZIP file containing a minimal Python environment. It is intended for acting as part of another application, rather than being directly accessed by end-users.

When extracted, the embedded distribution is (almost) fully isolated from the user's system, including environment variables, system registry settings, and installed packages. The standard library is included as pre-compiled and optimized `.pyc` files in a ZIP, and `python3.dll`, `python37.dll`, `python.exe` and `pythonw.exe` are all provided. Tcl/tk (including all dependents, such as Idle), pip and the Python documentation are not included.

### Note

The embedded distribution does not include the [Microsoft C Runtime](https://docs.microsoft.com/en-US/cpp/windows/latest-supported-vc-redist#visual-studio-2015-2017-2019-and-2022) [https://docs.microsoft.com/en-US/cpp/windows/latest-supported-vc-redist#visual-studio-2015-2017-2019-and-2022] and it is the responsibility of the application installer to provide this. The runtime may have already been installed on a user's system previously or automatically via Windows Update, and can be detected by finding `ucrtbase.dll` in the system directory.

Third-party packages should be installed by the application installer alongside the embedded distribution. Using pip to manage dependencies as for a regular Python installation is not supported with this distribution, though with some care it may be possible to

include and use pip for automatic updates. In general, third-party packages should be treated as part of the application (“vendoring”) so that the developer can ensure compatibility with newer versions before providing updates to users.

The two recommended use cases for this distribution are described below.

#### **4.4.1. Python Application**

An application written in Python does not necessarily require users to be aware of that fact. The embedded distribution may be used in this case to include a private version of Python in an install package. Depending on how transparent it should be (or conversely, how professional it should appear), there are two options.

Using a specialized executable as a launcher requires some coding, but provides the most transparent experience for users. With a customized launcher, there are no obvious indications that the program is running on Python: icons can be customized, company and version information can be specified, and file associations behave properly. In most cases, a custom launcher should simply be able to call `Py_Main` with a hard-coded command line.

The simpler approach is to provide a batch file or generated shortcut that directly calls the `python.exe` or `pythonw.exe` with the required command-line arguments. In this case, the application will appear to be Python and not its actual name, and users may have trouble distinguishing it from other running Python processes or file associations.

With the latter approach, packages should be installed as directories alongside the Python executable to ensure they are available on the path. With the specialized launcher, packages can be located in other locations as there is an opportunity to specify the search path before launching the application.

#### **4.4.2. Embedding Python**

Applications written in native code often require some form of

scripting language, and the embedded Python distribution can be used for this purpose. In general, the majority of the application is in native code, and some part will either invoke `python.exe` or directly use `python3.dll`. For either case, extracting the embedded distribution to a subdirectory of the application installation is sufficient to provide a loadable Python interpreter.

As with the application use, packages can be installed to any location as there is an opportunity to specify search paths before initializing the interpreter. Otherwise, there is no fundamental differences between using the embedded distribution and a regular installation.

## 4.5. Alternative bundles

Besides the standard CPython distribution, there are modified packages including additional functionality. The following is a list of popular versions and their key features:

**ActivePython** [<https://www.activestate.com/products/python/>]

Installer with multi-platform compatibility, documentation, PyWin32

**Anaconda** [<https://www.anaconda.com/download/>]

Popular scientific modules (such as numpy, scipy and pandas) and the `conda` package manager.

**Enthought Deployment Manager** [<https://www.enthought.com/edm/>]

“The Next Generation Python Environment and Package Manager”.

Previously Enthought provided Canopy, but it [reached end of life in 2016](https://support.enthought.com/hc/en-us/articles/360038600051-Canopy-GUI-end-of-life-transition-to-the-Enthought-Deployment-Manager-EDM-and-Visual-Studio-Code) [<https://support.enthought.com/hc/en-us/articles/360038600051-Canopy-GUI-end-of-life-transition-to-the-Enthought-Deployment-Manager-EDM-and-Visual-Studio-Code>].

**WinPython** [<https://winpython.github.io/>]

Windows-specific distribution with prebuilt scientific packages and tools for building packages.

Note that these packages may not include the latest versions of Python or other libraries, and are not maintained or supported by the core Python team.

## 4.6. Configuring Python

To run Python conveniently from a command prompt, you might consider changing some default environment variables in Windows. While the installer provides an option to configure the PATH and PATHEXT variables for you, this is only reliable for a single, system-wide installation. If you regularly use multiple versions of Python, consider using the [Python Launcher for Windows](#).

### 4.6.1. Excursus: Setting environment variables

Windows allows environment variables to be configured permanently at both the User level and the System level, or temporarily in a command prompt.

To temporarily set environment variables, open Command Prompt and use the **set** command:

```
C:\>set PATH=C:\Program Files\Python 3.9;%PATH%
C:\>set PYTHONPATH=%PYTHONPATH%;C:\My_python_lib
C:\>python
```

These changes will apply to any further commands executed in that console, and will be inherited by any applications started from the console.

Including the variable name within percent signs will expand to the existing value, allowing you to add your new value at either the start or the end. Modifying **PATH** by adding the directory containing **python.exe** to the start is a common way to ensure the correct version of Python is launched.

To permanently modify the default environment variables, click Start and search for ‘edit environment variables’, or open System properties, *Advanced system settings* and click the *Environment Variables* button. In this dialog, you can add or modify User and

System variables. To change System variables, you need non-restricted access to your machine (i.e. Administrator rights).

### Note

Windows will concatenate User variables *after* System variables, which may cause unexpected results when modifying **PATH**.

The **PYTHONPATH** variable is used by all versions of Python, so you should not permanently configure it unless the listed paths only include code that is compatible with all of your installed Python versions.

<https://docs.microsoft.com/en-us/windows-server/administration/windows-commands/setx>

The `setx` command, for permanently modifying environment variables

## 4.6.2. Finding the Python executable

*Changed in version 3.5.*

Besides using the automatically created start menu entry for the Python interpreter, you might want to start Python in the command prompt. The installer has an option to set that up for you.

On the first page of the installer, an option labelled “Add Python to PATH” may be selected to have the installer add the install location

into the **PATH**. The location of the `Scripts\` folder is also added. This allows you to type **python** to run the interpreter, and **pip** for the package installer. Thus, you can also execute your scripts with command line options, see [Command line](#) documentation.

If you don't enable this option at install time, you can always re-run the installer, select Modify, and enable it. Alternatively, you can manually modify the **PATH** using the directions in [Excursus: Setting environment variables](#). You need to set your **PATH** environment variable to include the directory of your Python installation, delimited by a semicolon from other entries. An example variable could look like this (assuming the first two entries already existed):

```
C:\WINDOWS\system32;C:\WINDOWS;C:\Program Files\Python 3
```

## 4.7. UTF-8 mode

*New in version 3.7.*

Windows still uses legacy encodings for the system encoding (the ANSI Code Page). Python uses it for the default encoding of text files (e.g. `locale.getencoding()`).

This may cause issues because UTF-8 is widely used on the internet and most Unix systems, including WSL (Windows Subsystem for Linux).

You can use the [Python UTF-8 Mode](#) to change the default text encoding to UTF-8. You can enable the [Python UTF-8 Mode](#) via the `-X utf8` command line option, or the `PYTHONUTF8=1` environment variable. See [PYTHONUTF8](#) for enabling UTF-8 mode, and [Excursus: Setting environment variables](#) for how to modify environment variables.

When the [Python UTF-8 Mode](#) is enabled, you can still use the system encoding (the ANSI Code Page) via the “mbcs” codec.

Note that adding `PYTHONUTF8=1` to the default environment variables will affect all Python 3.7+ applications on your system. If you have any Python 3.7+ applications which rely on the legacy system encoding, it is recommended to set the environment variable

temporarily or use the `-X utf8` command line option.

## Note

Even when UTF-8 mode is disabled, Python uses UTF-8 by default on Windows for:

- Console I/O including standard I/O (see [PEP 528](https://peps.python.org/pep-0528/) [https://peps.python.org/pep-0528/] for details).
- The [filesystem encoding](https://peps.python.org/pep-0529/) (see [PEP 529](https://peps.python.org/pep-0529/) [https://peps.python.org/pep-0529/] for details).

## 4.8. Python Launcher for Windows

*New in version 3.3.*

The Python launcher for Windows is a utility which aids in locating and executing of different Python versions. It allows scripts (or the command-line) to indicate a preference for a specific Python version, and will locate and execute that version.

Unlike the **PATH** variable, the launcher will correctly select the most appropriate version of Python. It will prefer per-user installations over system-wide ones, and orders by language version rather than using the most recently installed version.

The launcher was originally specified in [PEP 397](https://peps.python.org/pep-0397/) [https://peps.python.org/pep-0397/].

### 4.8.1. Getting started

#### 4.8.1.1. From the command-line

*Changed in version 3.6.*

System-wide installations of Python 3.3 and later will put the launcher on your **PATH**. The launcher is compatible with all available versions of Python, so it does not matter which version is installed. To check that the launcher is available, execute the

following command in Command Prompt:

```
py
```

You should find that the latest version of Python you have installed is started - it can be exited as normal, and any additional command-line arguments specified will be sent directly to Python.

If you have multiple versions of Python installed (e.g., 3.7 and 3.11) you will have noticed that Python 3.11 was started - to launch Python 3.7, try the command:

```
py -3.7
```

If you want the latest version of Python 2 you have installed, try the command:

```
py -2
```

If you see the following error, you do not have the launcher installed:

```
'py' is not recognized as an internal or external command,
operable program or batch file.
```

The command:

```
py --list
```

displays the currently installed version(s) of Python.

The `-x.y` argument is the short form of the `-V:Company/Tag` argument, which allows selecting a specific Python runtime, including those that may have come from somewhere other than python.org. Any runtime registered by following [PEP 514](https://peps.python.org/pep-0514/) [https://peps.python.org/pep-0514/] will be discoverable. The `--list` command lists all available runtimes using the `-V:` format.

When using the `-V:` argument, specifying the Company will limit selection to runtimes from that provider, while specifying only the Tag will select from all providers. Note that omitting the slash implies a tag:

```
# Select any '3.*' tagged runtime
py -V:3
```

```
# Select any 'PythonCore' released runtime
py -V:PythonCore/
```

```
# Select PythonCore's latest Python 3 runtime
py -V:PythonCore/3
```

The short form of the argument (`-3`) only ever selects from core Python releases, and not other distributions. However, the longer form (`-V:3`) will select from any.

The Company is matched on the full string, case-insensitive. The Tag is matched on either the full string, or a prefix, provided the next character is a dot or a hyphen. This allows `-V:3.1` to match `3.1-32`, but not `3.10`. Tags are sorted using numerical ordering (`3.10` is newer than `3.1`), but are compared using text (`-V:3.01` does not match `3.1`).

#### 4.8.1.2. Virtual environments

*New in version 3.5.*

If the launcher is run with no explicit Python version specification, and a virtual environment (created with the standard library `venv` module or the external `virtualenv` tool) active, the launcher will run the virtual environment's interpreter rather than the global one. To run the global interpreter, either deactivate the virtual environment, or explicitly specify the global Python version.

#### 4.8.1.3. From a script

Let's create a test Python script - create a file called `hello.py` with the following contents

```
#!/python
import sys
sys.stdout.write("hello from Python %s\n" % (sys.version))
```

From the directory in which `hello.py` lives, execute the command:

```
py hello.py
```

You should notice the version number of your latest Python 2.x installation is printed. Now try changing the first line to be:

```
#! python3
```

Re-executing the command should now print the latest Python 3.x information. As with the above command-line examples, you can specify a more explicit version qualifier. Assuming you have Python 3.7 installed, try changing the first line to `#! python3.7` and you should find the 3.7 version information printed.

Note that unlike interactive use, a bare “python” will use the latest version of Python 2.x that you have installed. This is for backward compatibility and for compatibility with Unix, where the command `python` typically refers to Python 2.

#### **4.8.1.4. From file associations**

The launcher should have been associated with Python files (i.e. `.py`, `.pyw`, `.pyc` files) when it was installed. This means that when you double-click on one of these files from Windows explorer the launcher will be used, and therefore you can use the same facilities described above to have the script specify the version which should be used.

The key benefit of this is that a single launcher can support multiple Python versions at the same time depending on the contents of the first line.

#### **4.8.2. Shebang Lines**

If the first line of a script file starts with `#!`, it is known as a “shebang” line. Linux and other Unix like operating systems have native support for such lines and they are commonly used on such systems to indicate how a script should be executed. This launcher allows the same facilities to be used with Python scripts on Windows and the examples above demonstrate their use.

To allow shebang lines in Python scripts to be portable between Unix and Windows, this launcher supports a number of ‘virtual’ commands to specify which interpreter to use. The supported virtual commands are:

- `/usr/bin/env`
- `/usr/bin/python`
- `/usr/local/bin/python`
- `python`

For example, if the first line of your script starts with

```
#!/usr/bin/python
```

The default Python will be located and used. As many Python scripts written to work on Unix will already have this line, you should find these scripts can be used by the launcher without modification. If you are writing a new script on Windows which you hope will be useful on Unix, you should use one of the shebang lines starting with `/usr.`

Any of the above virtual commands can be suffixed with an explicit version (either just the major version, or the major and minor version). Furthermore the 32-bit version can be requested by adding “-32” after the minor version. I.e. `/usr/bin/python3.7-32` will request usage of the 32-bit python 3.7.

*New in version 3.7:* Beginning with python launcher 3.7 it is possible to request 64-bit version by the “-64” suffix. Furthermore it is possible to specify a major and architecture without minor (i.e. `/usr/bin/python3-64`).

*Changed in version 3.11:* The “-64” suffix is deprecated, and now implies “any architecture that is not provably i386/32-bit”. To request a specific environment, use the new `-V:<TAG>` argument with the complete tag.

The `/usr/bin/env` form of shebang line has one further special property. Before looking for installed Python interpreters, this form will search the executable **PATH** for a Python executable matching the name provided as the first argument. This corresponds to the

behaviour of the Unix `env` program, which performs a **PATH** search. If an executable matching the first argument after the `env` command cannot be found, but the argument starts with `python`, it will be handled as described for the other virtual commands. The environment variable **PYLAUNCHER\_NO\_SEARCH\_PATH** may be set (to any value) to skip this search of **PATH**.

Shebang lines that do not match any of these patterns are looked up in the `[commands]` section of the launcher's [.INI file](#). This may be used to handle certain commands in a way that makes sense for your system. The name of the command must be a single argument (no spaces in the shebang executable), and the value substituted is the full path to the executable (additional arguments specified in the .INI will be quoted as part of the filename).

```
[commands]  
/bin/xpython=C:\Program Files\XPython\python.exe
```

Any commands not found in the .INI file are treated as **Windows** executable paths that are absolute or relative to the directory containing the script file. This is a convenience for Windows-only scripts, such as those generated by an installer, since the behavior is not compatible with Unix-style shells. These paths may be quoted, and may include multiple arguments, after which the path to the script and any additional arguments will be appended.

### 4.8.3. Arguments in shebang lines

The shebang lines can also specify additional options to be passed to the Python interpreter. For example, if you have a shebang line:

```
#!/usr/bin/python -v
```

Then Python will be started with the `-v` option

### 4.8.4. Customization

#### 4.8.4.1. Customization via INI files

Two .ini files will be searched by the launcher - `py.ini` in the

current user's application data directory (%LOCALAPPDATA% or \$env:LocalAppData) and `py.ini` in the same directory as the launcher. The same `.ini` files are used for both the 'console' version of the launcher (i.e. `py.exe`) and for the 'windows' version (i.e. `pyw.exe`).

Customization specified in the "application directory" will have precedence over the one next to the executable, so a user, who may not have write access to the `.ini` file next to the launcher, can override commands in that global `.ini` file.

#### 4.8.4.2. Customizing default Python versions

In some cases, a version qualifier can be included in a command to dictate which version of Python will be used by the command. A version qualifier starts with a major version number and can optionally be followed by a period ('.') and a minor version specifier. Furthermore it is possible to specify if a 32 or 64 bit implementation shall be requested by adding "-32" or "-64".

For example, a shebang line of `#!/python` has no version qualifier, while `#!/python3` has a version qualifier which specifies only a major version.

If no version qualifiers are found in a command, the environment variable **PY\_PYTHON** can be set to specify the default version qualifier. If it is not set, the default is "3". The variable can specify any value that may be passed on the command line, such as "3", "3.7", "3.7-32" or "3.7-64". (Note that the "-64" option is only available with the launcher included with Python 3.7 or newer.)

If no minor version qualifiers are found, the environment variable `PY_PYTHON{major}` (where {major} is the current major version qualifier as determined above) can be set to specify the full version. If no such option is found, the launcher will enumerate the installed Python versions and use the latest minor release found for the major version, which is likely, although not guaranteed, to be the most recently installed version in that family.

On 64-bit Windows with both 32-bit and 64-bit implementations of the same (major.minor) Python version installed, the 64-bit version

will always be preferred. This will be true for both 32-bit and 64-bit implementations of the launcher - a 32-bit launcher will prefer to execute a 64-bit Python installation of the specified version if available. This is so the behavior of the launcher can be predicted knowing only what versions are installed on the PC and without regard to the order in which they were installed (i.e., without knowing whether a 32 or 64-bit version of Python and corresponding launcher was installed last). As noted above, an optional “-32” or “-64” suffix can be used on a version specifier to change this behaviour.

Examples:

- If no relevant options are set, the commands `python` and `python2` will use the latest Python 2.x version installed and the command `python3` will use the latest Python 3.x installed.
- The command `python3.7` will not consult any options at all as the versions are fully specified.
- If `PY_PYTHON=3`, the commands `python` and `python3` will both use the latest installed Python 3 version.
- If `PY_PYTHON=3.7-32`, the command `python` will use the 32-bit implementation of 3.7 whereas the command `python3` will use the latest installed Python (`PY_PYTHON` was not considered at all as a major version was specified.)
- If `PY_PYTHON=3` and `PY_PYTHON3=3.7`, the commands `python` and `python3` will both use specifically 3.7

In addition to environment variables, the same settings can be configured in the .INI file used by the launcher. The section in the INI file is called `[defaults]` and the key name will be the same as the environment variables without the leading `PY_` prefix (and note that the key names in the INI file are case insensitive.) The contents of an environment variable will override things specified in the INI file.

For example:

- Setting `PY_PYTHON=3.7` is equivalent to the INI file containing:

```
[defaults]  
python=3.7
```

- Setting `PY_PYTHON=3` and `PY_PYTHON3=3.7` is equivalent to the INI file containing:

```
[defaults]  
python=3  
python3=3.7
```

### 4.8.5. Diagnostics

If an environment variable **PYLAUNCHER\_DEBUG** is set (to any value), the launcher will print diagnostic information to stderr (i.e. to the console). While this information manages to be simultaneously verbose *and* terse, it should allow you to see what versions of Python were located, why a particular version was chosen and the exact command-line used to execute the target Python. It is primarily intended for testing and debugging.

### 4.8.6. Dry Run

If an environment variable **PYLAUNCHER\_DRYRUN** is set (to any value), the launcher will output the command it would have run, but will not actually launch Python. This may be useful for tools that want to use the launcher to detect and then launch Python directly. Note that the command written to standard output is always encoded using UTF-8, and may not render correctly in the console.

### 4.8.7. Install on demand

If an environment variable **PYLAUNCHER\_ALLOW\_INSTALL** is set (to any value), and the requested Python version is not installed but is available on the Microsoft Store, the launcher will attempt to install it. This may require user interaction to complete, and you may need to run the command again.

An additional **PYLAUNCHER\_ALWAYS\_INSTALL** variable causes the launcher to always try to install Python, even if it is detected. This

is mainly intended for testing (and should be used with `PYLAUNCHER_DRYRUN`).

### 4.8.8. Return codes

The following exit codes may be returned by the Python launcher. Unfortunately, there is no way to distinguish these from the exit code of Python itself.

The names of codes are as used in the sources, and are only for reference. There is no way to access or resolve them apart from reading this page. Entries are listed in alphabetical order of names.

Name	Description
<code>NO_BAD_VENV_CFG</code>	As found but is corrupt.
<code>NO_CREATE_PROCESS</code>	Failed to create process.
<code>NO_INSTALLING</code>	Started, but the command will need to be re-run after it completes.
<code>NO_PYTHON_PATH</code>	Base report a bug.
<code>NO_SYSTEM_PATH</code>	Invalid command line from the operating system.
<code>NO_PYTHON_VERSION</code>	Not the requested version.
<code>NO_VENV_CFG</code>	As required but not found.

## 4.9. Finding modules

These notes supplement the description at [The initialization of the `sys.path` module search path](#) with detailed Windows notes.

When no `._pth` file is found, this is how `sys.path` is populated on Windows:

- An empty entry is added at the start, which corresponds to the current directory.
- If the environment variable `PYTHONPATH` exists, as described in [Environment variables](#), its entries are added next. Note that on Windows, paths in this variable must be separated by semicolons, to distinguish them from the colon used in drive identifiers (`C:\` etc.).
- Additional “application paths” can be added in the registry as subkeys of `\SOFTWARE\Python`

`\PythonCore{version}\PythonPath` under both the `HKEY_CURRENT_USER` and `HKEY_LOCAL_MACHINE` hives. Subkeys which have semicolon-delimited path strings as their default value will cause each path to be added to `sys.path`. (Note that all known installers only use `HKLM`, so `HKCU` is typically empty.)

- If the environment variable `PYTHONHOME` is set, it is assumed as “Python Home”. Otherwise, the path of the main Python executable is used to locate a “landmark file” (either `Lib\os.py` or `pythonXY.zip`) to deduce the “Python Home”. If a Python home is found, the relevant sub-directories added to `sys.path` (`Lib`, `plat-win`, etc) are based on that folder. Otherwise, the core Python path is constructed from the `PythonPath` stored in the registry.
- If the Python Home cannot be located, no `PYTHONPATH` is specified in the environment, and no registry entries can be found, a default path with relative entries is used (e.g. `.\Lib; .\plat-win`, etc).

If a `pyvenv.cfg` file is found alongside the main executable or in the directory one level above the executable, the following variations apply:

- If `home` is an absolute path and `PYTHONHOME` is not set, this path is used instead of the path to the main executable when deducing the home location.

The end result of all this is:

- When running `python.exe`, or any other `.exe` in the main Python directory (either an installed version, or directly from the `PCbuild` directory), the core path is deduced, and the core paths in the registry are ignored. Other “application paths” in the registry are always read.
- When Python is hosted in another `.exe` (different directory, embedded via COM, etc), the “Python Home” will not be deduced, so the core path from the registry is used. Other “application paths” in the registry are always read.
- If Python can’t find its home and there are no registry value (frozen `.exe`, some very strange installation setup) you get a path with some default, but relative, paths.

For those who want to bundle Python into their application or distribution, the following advice will prevent conflicts with other installations:

- Include a `._pth` file alongside your executable containing the directories to include. This will ignore paths listed in the registry and environment variables, and also ignore `site` unless `import site` is listed.
- If you are loading `python3.dll` or `python37.dll` in your own executable, explicitly call `Py_SetPath()` or (at least) `Py_SetProgramName()` before `Py_Initialize()`.
- Clear and/or overwrite `PYTHONPATH` and set `PYTHONHOME` before launching `python.exe` from your application.
- If you cannot use the previous suggestions (for example, you are a distribution that allows people to run `python.exe` directly), ensure that the landmark file (`Lib\os.py`) exists in your install directory. (Note that it will not be detected inside a ZIP file, but a correctly named ZIP file will be detected instead.)

These will ensure that the files in a system-wide installation will not take precedence over the copy of the standard library bundled with your application. Otherwise, your users may experience problems using your application. Note that the first suggestion is the best, as the others may still be susceptible to non-standard paths in the registry and user site-packages.

*Changed in version 3.6:*

- Adds `._pth` file support and removes `applocal` option from `pyenvv.cfg`.
- Adds `pythonXX.zip` as a potential landmark when directly adjacent to the executable.

*Deprecated since version 3.6:*

Modules specified in the registry under `Modules` (not `PythonPath`) may be imported by `importlib.machinery.WindowsRegistryFinder`. This finder is enabled on Windows in 3.6.0 and

earlier, but may need to be explicitly added to `sys.meta_path` in the future.

## 4.10. Additional modules

Even though Python aims to be portable among all platforms, there are features that are unique to Windows. A couple of modules, both in the standard library and external, and snippets exist to use these features.

The Windows-specific standard modules are documented in [MS Windows Specific Services](#).

### 4.10.1. PyWin32

The [PyWin32](#) [<https://pypi.org/project/pywin32>] module by Mark Hammond is a collection of modules for advanced Windows-specific support. This includes utilities for:

- [Component Object Model](#) [<https://docs.microsoft.com/en-us/windows/win32/com/component-object-model--com--portal>] (COM)
- Win32 API calls
- Registry
- Event log
- [Microsoft Foundation Classes](#) [<https://docs.microsoft.com/en-us/cpp/mfc/mfc-desktop-applications>] (MFC) user interfaces

[PythonWin](#) [<https://web.archive.org/web/20060524042422/https://www.python.org/windows/pythonwin/>] is a sample MFC application shipped with PyWin32. It is an embeddable IDE with a built-in debugger.

**See also**

[Win32 How Do I...?](#) [[http://timgolden.me.uk/python/win32\\_how\\_do\\_i.html](http://timgolden.me.uk/python/win32_how_do_i.html)]  
by Tim Golden

[Python and COM](#) [<https://www.boddie.org.uk/python/COM.html>]  
by David and Paul Boddie

### 4.10.2. cx\_Freeze

**cx\_Freeze** [<https://cx-freeze.readthedocs.io/en/latest/>] is a **distutils** extension (see [Extending Distutils](#)) which wraps Python scripts into executable Windows programs (`*.exe` files). When you have done this, you can distribute your application without requiring your users to install Python.

## 4.11. Compiling Python on Windows

If you want to compile CPython yourself, first thing you should do is get the **source** [<https://www.python.org/downloads/source/>]. You can download either the latest release's source or just grab a fresh **checkout** [<https://devguide.python.org/setup/#get-the-source-code>].

The source tree contains a build solution and project files for Microsoft Visual Studio, which is the compiler used to build the official Python releases. These files are in the `PCbuild` directory.

Check `PCbuild/readme.txt` for general information on the build process.

For extension modules, consult [Building C and C++ Extensions on Windows](#).

## 4.12. Other Platforms

With ongoing development of Python, some platforms that used to be supported earlier are no longer supported (due to the lack of users or developers). Check **PEP 11** [<https://peps.python.org/pep-0011/>] for details on all unsupported platforms.

- **Windows CE** [<https://pythonce.sourceforge.net/>] is **no longer supported** [<https://github.com/python/cpython/issues/71542>] since Python 3 (if it ever was).
- The **Cygwin** [<https://cygwin.com/>] installer offers to install the **Python interpreter** [<https://cygwin.com/packages/summary/python3.html>] as well

See [Python for Windows](https://www.python.org/downloads/windows/) [https://www.python.org/downloads/windows/] for detailed information about platforms with pre-compiled installers.

# 5. Using Python on a Mac

Author

Bob Savage <[bobsavage@mac.com](mailto:bobsavage@mac.com)>

Python on a Mac running macOS is in principle very similar to Python on any other Unix platform, but there are a number of additional features such as the IDE and the Package Manager that are worth pointing out.

## 5.1. Getting and Installing MacPython

macOS used to come with Python 2.7 pre-installed between versions 10.8 and 12.3 [[https://developer.apple.com/documentation/macos-release-notes/macos-12\\_3-release-notes#Python](https://developer.apple.com/documentation/macos-release-notes/macos-12_3-release-notes#Python)]. You are invited to install the most recent version of Python 3 from the Python website (<https://www.python.org>). A current “universal binary” build of Python, which runs natively on the Mac’s new Intel and legacy PPC CPU’s, is available there.

What you get after installing is a number of things:

- A `Python 3.12` folder in your `Applications` folder. In here you find `IDLE`, the development environment that is a standard part of official Python distributions; and `PythonLauncher`, which handles double-clicking Python scripts from the Finder.
- A framework `/Library/Frameworks/Python.framework`, which includes the Python executable and libraries. The installer adds this location to your shell path. To uninstall MacPython, you can simply remove these three things. A symlink to the Python executable is placed in `/usr/local/bin/`.

The Apple-provided build of Python is installed in `/System/Library/Frameworks/Python.framework` and `/usr/bin/`

python, respectively. You should never modify or delete these, as they are Apple-controlled and are used by Apple- or third-party software. Remember that if you choose to install a newer Python version from python.org, you will have two different but functional Python installations on your computer, so it will be important that your paths and usages are consistent with what you want to do.

IDLE includes a help menu that allows you to access Python documentation. If you are completely new to Python you should start reading the tutorial introduction in that document.

If you are familiar with Python on other Unix platforms you should read the section on running Python scripts from the Unix shell.

### 5.1.1. How to run a Python script

Your best way to get started with Python on macOS is through the IDLE integrated development environment, see section [The IDE](#) and use the Help menu when the IDE is running.

If you want to run Python scripts from the Terminal window command line or from the Finder you first need an editor to create your script. macOS comes with a number of standard Unix command line editors, **vim** and **emacs** among them. If you want a more Mac-like editor, **BEdit** or **TextWrangler** from Bare Bones Software (see <http://www.barebones.com/products/bbedit/index.html>) are good choices, as is **TextMate** (see <https://macromates.com/>). Other editors include **Gvim** (<https://macvim.org/macvim/>) and **Aquamacs** (<http://aquamacs.org/>).

To run your script from the Terminal window you must make sure that `/usr/local/bin` is in your shell search path.

To run your script from the Finder you have two options:

- Drag it to **PythonLauncher**
- Select **PythonLauncher** as the default application to open your script (or any .py script) through the finder Info window and double-click it. **PythonLauncher** has various preferences to control how your script is launched. Option-dragging allows you to change these for one invocation, or use its

Preferences menu to change things globally.

### 5.1.2. Running scripts with a GUI

With older versions of Python, there is one macOS quirk that you need to be aware of: programs that talk to the Aqua window manager (in other words, anything that has a GUI) need to be run in a special way. Use **pythonw** instead of **python** to start such scripts.

With Python 3.9, you can use either **python** or **pythonw**.

### 5.1.3. Configuration

Python on macOS honors all standard Unix environment variables such as **PYTHONPATH**, but setting these variables for programs started from the Finder is non-standard as the Finder does not read your `.profile` or `.cshrc` at startup. You need to create a file `~/MacOSX/environment.plist`. See Apple's Technical Document QA1067 for details.

For more information on installation Python packages in MacPython, see section [Installing Additional Python Packages](#).

## 5.2. The IDE

MacPython ships with the standard IDLE development environment. A good introduction to using IDLE can be found at [http://www.hashcollision.org/hkn/python/idle\\_intro/index.html](http://www.hashcollision.org/hkn/python/idle_intro/index.html).

## 5.3. Installing Additional Python Packages

There are several methods to install additional Python packages:

- Packages can be installed via the standard Python distutils mode (`python setup.py install`).
- Many packages can also be installed via the **setuptools** extension or **pip** wrapper, see <https://pip.pypa.io/>.

## 5.4. GUI Programming on the Mac

There are several options for building GUI applications on the Mac with Python.

*PyObjC* is a Python binding to Apple's Objective-C/Cocoa framework, which is the foundation of most modern Mac development. Information on PyObjC is available from <https://pypi.org/project/pyobjc/>.

The standard Python GUI toolkit is **tkinter**, based on the cross-platform Tk toolkit (<https://www.tcl.tk>). An Aqua-native version of Tk is bundled with OS X by Apple, and the latest version can be downloaded and installed from <https://www.activestate.com>; it can also be built from source.

*wxPython* is another popular cross-platform GUI toolkit that runs natively on macOS. Packages and documentation are available from <https://www.wxpython.org>.

*PyQt* is another popular cross-platform GUI toolkit that runs natively on macOS. More information can be found at <https://riverbankcomputing.com/software/pyqt/intro>.

## 5.5. Distributing Python Applications on the Mac

The standard tool for deploying standalone Python applications on the Mac is **py2app**. More information on installing and using py2app can be found at <https://pypi.org/project/py2app/>.

## 5.6. Other Resources

The MacPython mailing list is an excellent support resource for Python users and developers on the Mac:

<https://www.python.org/community/sigs/current/pythonmac-sig/>

Another useful resource is the MacPython wiki:

<https://wiki.python.org/moin/MacPython>

## 6. Editors and IDEs

There are a number of IDEs that support Python programming language. Many editors and IDEs provide syntax highlighting, debugging tools, and **PEP 8** [<https://peps.python.org/pep-0008/>] checks.

Please go to [Python Editors](https://wiki.python.org/moin/PythonEditors) [<https://wiki.python.org/moin/PythonEditors>] and [Integrated Development Environments](https://wiki.python.org/moin/IntegratedDevelopmentEnvironments) [<https://wiki.python.org/moin/IntegratedDevelopmentEnvironments>] for a comprehensive list.

# The Python Language Reference

This reference manual describes the syntax and “core semantics” of the language. It is terse, but attempts to be exact and complete. The semantics of non-essential built-in object types and of the built-in functions and modules are described in [The Python Standard Library](#). For an informal introduction to the language, see [The Python Tutorial](#). For C or C++ programmers, two additional manuals exist: [Extending and Embedding the Python Interpreter](#) describes the high-level picture of how to write a Python extension module, and the [Python/C API Reference Manual](#) describes the interfaces available to C/C++ programmers in detail.

# 1. Introduction

This reference manual describes the Python programming language. It is not intended as a tutorial.

While I am trying to be as precise as possible, I chose to use English rather than formal specifications for everything except syntax and lexical analysis. This should make the document more understandable to the average reader, but will leave room for ambiguities. Consequently, if you were coming from Mars and tried to re-implement Python from this document alone, you might have to guess things and in fact you would probably end up implementing quite a different language. On the other hand, if you are using Python and wonder what the precise rules about a particular area of the language are, you should definitely be able to find them here. If you would like to see a more formal definition of the language, maybe you could volunteer your time — or invent a cloning machine :-).

It is dangerous to add too many implementation details to a language reference document — the implementation may change, and other implementations of the same language may work differently. On the other hand, CPython is the one Python implementation in widespread use (although alternate implementations continue to gain support), and its particular quirks are sometimes worth being mentioned, especially where the implementation imposes additional limitations. Therefore, you'll find short “implementation notes” sprinkled throughout the text.

Every Python implementation comes with a number of built-in and standard modules. These are documented in [The Python Standard Library](#). A few built-in modules are mentioned when they interact in a significant way with the language definition.

## 1.1. Alternate Implementations

Though there is one Python implementation which is by far the most popular, there are some alternate implementations which are of particular interest to different audiences.

Known implementations include:

### CPython

This is the original and most-maintained implementation of Python, written in C. New language features generally appear here first.

### Jython

Python implemented in Java. This implementation can be used as a scripting language for Java applications, or can be used to create applications using the Java class libraries. It is also often used to create tests for Java libraries. More information can be found at [the Jython website](https://www.jython.org/) [https://www.jython.org/].

### Python for .NET

This implementation actually uses the CPython implementation, but is a managed .NET application and makes .NET libraries available. It was created by Brian Lloyd. For more information, see the [Python for .NET home page](https://pythonnet.github.io/) [https://pythonnet.github.io/].

### IronPython

An alternate Python for .NET. Unlike Python.NET, this is a complete Python implementation that generates IL, and compiles Python code directly to .NET assemblies. It was created by Jim Hugunin, the original creator of Jython. For more information, see [the IronPython website](https://ironpython.net/) [https://ironpython.net/].

### PyPy

An implementation of Python written completely in Python. It supports several advanced features not found in other implementations like stackless support and a Just in Time compiler. One of the goals of the project is to encourage experimentation with the language itself by making it easier to modify the interpreter (since it is written in Python).

Additional information is available on [the PyPy project's home page](https://www.pypy.org/) [https://www.pypy.org/].

Each of these implementations varies in some way from the language as documented in this manual, or introduces specific information beyond what's covered in the standard Python documentation. Please refer to the implementation-specific documentation to determine what else you need to know about the specific implementation you're using.

## 1.2. Notation

The descriptions of lexical analysis and syntax use a modified BNF grammar notation. This uses the following style of definition:

```
name          ::= lc_letter (lc_letter | "_" ) *  
lc_letter ::= "a" ... "z"
```

The first line says that a `name` is an `lc_letter` followed by a sequence of zero or more `lc_letters` and underscores. An `lc_letter` in turn is any of the single characters 'a' through 'z'. (This rule is actually adhered to for the names defined in lexical and grammar rules in this document.)

Each rule begins with a name (which is the name defined by the rule) and `::=`. A vertical bar (`|`) is used to separate alternatives; it is the least binding operator in this notation. A star (`*`) means zero or more repetitions of the preceding item; likewise, a plus (`+`) means one or more repetitions, and a phrase enclosed in square brackets (`[ ]`) means zero or one occurrences (in other words, the enclosed phrase is optional). The `*` and `+` operators bind as tightly as possible; parentheses are used for grouping. Literal strings are enclosed in quotes. White space is only meaningful to separate tokens. Rules are normally contained on a single line; rules with many alternatives may be formatted alternatively with each line after the first beginning with a vertical bar.

In lexical definitions (as the example above), two more conventions are used: Two literal characters separated by three dots mean a

choice of any single character in the given (inclusive) range of ASCII characters. A phrase between angular brackets (< . . >) gives an informal description of the symbol defined; e.g., this could be used to describe the notion of ‘control character’ if needed.

Even though the notation used is almost the same, there is a big difference between the meaning of lexical and syntactic definitions: a lexical definition operates on the individual characters of the input source, while a syntax definition operates on the stream of tokens generated by the lexical analysis. All uses of BNF in the next chapter (“Lexical Analysis”) are lexical definitions; uses in subsequent chapters are syntactic definitions.

## 2. Lexical analysis

A Python program is read by a *parser*. Input to the parser is a stream of *tokens*, generated by the *lexical analyzer*. This chapter describes how the lexical analyzer breaks a file into tokens.

Python reads program text as Unicode code points; the encoding of a source file can be given by an encoding declaration and defaults to UTF-8, see [PEP 3120](https://peps.python.org/pep-3120/) [https://peps.python.org/pep-3120/] for details. If the source file cannot be decoded, a `SyntaxError` is raised.

### 2.1. Line structure

A Python program is divided into a number of *logical lines*.

#### 2.1.1. Logical lines

The end of a logical line is represented by the token `NEWLINE`. Statements cannot cross logical line boundaries except where `NEWLINE` is allowed by the syntax (e.g., between statements in compound statements). A logical line is constructed from one or more *physical lines* by following the explicit or implicit *line joining* rules.

#### 2.1.2. Physical lines

A physical line is a sequence of characters terminated by an end-of-line sequence. In source files and strings, any of the standard platform line termination sequences can be used - the Unix form using ASCII LF (linefeed), the Windows form using the ASCII sequence CR LF (return followed by linefeed), or the old Macintosh form using the ASCII CR (return) character. All of these forms can be used equally, regardless of platform. The end of input also serves as an implicit terminator for the final physical line.

When embedding Python, source code strings should be passed to Python APIs using the standard C conventions for newline characters (the `\n` character, representing ASCII LF, is the line terminator).

### 2.1.3. Comments

A comment starts with a hash character (`#`) that is not part of a string literal, and ends at the end of the physical line. A comment signifies the end of the logical line unless the implicit line joining rules are invoked. Comments are ignored by the syntax.

### 2.1.4. Encoding declarations

If a comment in the first or second line of the Python script matches the regular expression `coding[=:]\s*([-w.]+)`, this comment is processed as an encoding declaration; the first group of this expression names the encoding of the source code file. The encoding declaration must appear on a line of its own. If it is the second line, the first line must also be a comment-only line. The recommended forms of an encoding expression are

```
# -*- coding: <encoding-name> -*-
```

which is recognized also by GNU Emacs, and

```
# vim:fileencoding=<encoding-name>
```

which is recognized by Bram Moolenaar's VIM.

If no encoding declaration is found, the default encoding is UTF-8. In addition, if the first bytes of the file are the UTF-8 byte-order mark (`b'\xef\xbb\xbf'`), the declared file encoding is UTF-8 (this is supported, among others, by Microsoft's **notepad**).

If an encoding is declared, the encoding name must be recognized by Python (see [Standard Encodings](#)). The encoding is used for all lexical analysis, including string literals, comments and identifiers.

### 2.1.5. Explicit line joining

Two or more physical lines may be joined into logical lines using backslash characters (\), as follows: when a physical line ends in a backslash that is not part of a string literal or comment, it is joined with the following forming a single logical line, deleting the backslash and the following end-of-line character. For example:

```
if 1900 < year < 2100 and 1 <= month <= 12 \  
    and 1 <= day <= 31 and 0 <= hour < 24 \  
    and 0 <= minute < 60 and 0 <= second < 60:    # Looks  
    return 1
```

A line ending in a backslash cannot carry a comment. A backslash does not continue a comment. A backslash does not continue a token except for string literals (i.e., tokens other than string literals cannot be split across physical lines using a backslash). A backslash is illegal elsewhere on a line outside a string literal.

### 2.1.6. Implicit line joining

Expressions in parentheses, square brackets or curly braces can be split over more than one physical line without using backslashes. For example:

```
month_names = ['Januari', 'Februari', 'Maart',          # Th  
               'April',   'Mei',      'Juni',         # Du  
               'Juli',    'Augustus', 'September',   # fo  
               'Oktober', 'November', 'December']    # of
```

Implicitly continued lines can carry comments. The indentation of the continuation lines is not important. Blank continuation lines are allowed. There is no NEWLINE token between implicit continuation lines. Implicitly continued lines can also occur within triple-quoted strings (see below); in that case they cannot carry comments.

### 2.1.7. Blank lines

A logical line that contains only spaces, tabs, formfeeds and possibly a comment, is ignored (i.e., no NEWLINE token is generated). During interactive input of statements, handling of a blank line may differ depending on the implementation of the read-

eval-print loop. In the standard interactive interpreter, an entirely blank logical line (i.e. one containing not even whitespace or a comment) terminates a multi-line statement.

### 2.1.8. Indentation

Leading whitespace (spaces and tabs) at the beginning of a logical line is used to compute the indentation level of the line, which in turn is used to determine the grouping of statements.

Tabs are replaced (from left to right) by one to eight spaces such that the total number of characters up to and including the replacement is a multiple of eight (this is intended to be the same rule as used by Unix). The total number of spaces preceding the first non-blank character then determines the line's indentation. Indentation cannot be split over multiple physical lines using backslashes; the whitespace up to the first backslash determines the indentation.

Indentation is rejected as inconsistent if a source file mixes tabs and spaces in a way that makes the meaning dependent on the worth of a tab in spaces; a **TabError** is raised in that case.

**Cross-platform compatibility note:** because of the nature of text editors on non-UNIX platforms, it is unwise to use a mixture of spaces and tabs for the indentation in a single source file. It should also be noted that different platforms may explicitly limit the maximum indentation level.

A formfeed character may be present at the start of the line; it will be ignored for the indentation calculations above. Formfeed characters occurring elsewhere in the leading whitespace have an undefined effect (for instance, they may reset the space count to zero).

The indentation levels of consecutive lines are used to generate INDENT and DEDENT tokens, using a stack, as follows.

Before the first line of the file is read, a single zero is pushed on the stack; this will never be popped off again. The numbers pushed on the stack will always be strictly increasing from bottom to top. At

the beginning of each logical line, the line's indentation level is compared to the top of the stack. If it is equal, nothing happens. If it is larger, it is pushed on the stack, and one INDENT token is generated. If it is smaller, it *must* be one of the numbers occurring on the stack; all numbers on the stack that are larger are popped off, and for each number popped off a DEDENT token is generated. At the end of the file, a DEDENT token is generated for each number remaining on the stack that is larger than zero.

Here is an example of a correctly (though confusingly) indented piece of Python code:

```
def perm(l):
    # Compute the list of all permutations of l
    if len(l) <= 1:
        return [l]
    r = []
    for i in range(len(l)):
        s = l[:i] + l[i+1:]
        p = perm(s)
        for x in p:
            r.append(l[i:i+1] + x)
    return r
```

The following example shows various indentation errors:

```
def perm(l):                                # error: first line
for i in range(len(l)):                     # error: not indented
    s = l[:i] + l[i+1:]
    p = perm(l[:i] + l[i+1:])               # error: unexpected
    for x in p:
        r.append(l[i:i+1] + x)
    return r                                # error: inconsistent
```

(Actually, the first three errors are detected by the parser; only the last error is found by the lexical analyzer — the indentation of `return r` does not match a level popped off the stack.)

### 2.1.9. Whitespace between tokens

Except at the beginning of a logical line or in string literals, the whitespace characters space, tab and formfeed can be used interchangeably to separate tokens. Whitespace is needed between two tokens only if their concatenation could otherwise be interpreted as a different token (e.g., `ab` is one token, but `a b` is two tokens).

## 2.2. Other tokens

Besides `NEWLINE`, `INDENT` and `DEDENT`, the following categories of tokens exist: *identifiers*, *keywords*, *literals*, *operators*, and *delimiters*. Whitespace characters (other than line terminators, discussed earlier) are not tokens, but serve to delimit tokens. Where ambiguity exists, a token comprises the longest possible string that forms a legal token, when read from left to right.

## 2.3. Identifiers and keywords

Identifiers (also referred to as *names*) are described by the following lexical definitions.

The syntax of identifiers in Python is based on the Unicode standard annex UAX-31, with elaboration and changes as defined below; see also [PEP 3131](https://peps.python.org/pep-3131/) [https://peps.python.org/pep-3131/] for further details.

Within the ASCII range (U+0001..U+007F), the valid characters for identifiers are the same as in Python 2.x: the uppercase and lowercase letters `A` through `Z`, the underscore `_` and, except for the first character, the digits `0` through `9`.

Python 3.0 introduces additional characters from outside the ASCII range (see [PEP 3131](https://peps.python.org/pep-3131/) [https://peps.python.org/pep-3131/]). For these characters, the classification uses the version of the Unicode Character Database as included in the `unicodedata` module.

Identifiers are unlimited in length. Case is significant.

```
identifier ::= xid_start xid_continue*  
id_start  ::= <all characters in general categories
```

```
id_continue ::= <all characters in id_start, plus char  
xid_start   ::= <all characters in id_start whose NFKC  
xid_continue ::= <all characters in id_continue whose N
```

The Unicode category codes mentioned above stand for:

- *Lu* - uppercase letters
- *Ll* - lowercase letters
- *Lt* - titlecase letters
- *Lm* - modifier letters
- *Lo* - other letters
- *Nl* - letter numbers
- *Mn* - nonspacing marks
- *Mc* - spacing combining marks
- *Nd* - decimal numbers
- *Pc* - connector punctuations
- *Other\_ID\_Start* - explicit list of characters in [PropList.txt](https://www.unicode.org/Public/14.0.0/ucd/PropList.txt)  
[<https://www.unicode.org/Public/14.0.0/ucd/PropList.txt>] to support  
backwards compatibility
- *Other\_ID\_Continue* - likewise

All identifiers are converted into the normal form NFKC while parsing; comparison of identifiers is based on NFKC.

A non-normative HTML file listing all valid identifier characters for Unicode 14.0.0 can be found at <https://www.unicode.org/Public/14.0.0/ucd/DerivedCoreProperties.txt>

### 2.3.1. Keywords

The following identifiers are used as reserved words, or *keywords* of the language, and cannot be used as ordinary identifiers. They must be spelled exactly as written here:

False	await	else	import	pass
None	break	except	in	raise
True	class	finally	is	return
and	continue	for	lambda	try
as	def	from	nonlocal	while
assert	del	global	not	with

`async`      `elif`      `if`      `or`      `yield`

## 2.3.2. Soft Keywords

*New in version 3.10.*

Some identifiers are only reserved under specific contexts. These are known as *soft keywords*. The identifiers `match`, `case` and `_` can syntactically act as keywords in contexts related to the pattern matching statement, but this distinction is done at the parser level, not when tokenizing.

As soft keywords, their use with pattern matching is possible while still preserving compatibility with existing code that uses `match`, `case` and `_` as identifier names.

## 2.3.3. Reserved classes of identifiers

Certain classes of identifiers (besides keywords) have special meanings. These classes are identified by the patterns of leading and trailing underscore characters:

`_*`  
Not imported by `from module import *`.

—  
In a `case` pattern within a `match` statement, `_` is a [soft keyword](#) that denotes a [wildcard](#).

Separately, the interactive interpreter makes the result of the last evaluation available in the variable `_`. (It is stored in the [builtins](#) module, alongside built-in functions like `print`.)

Elsewhere, `_` is a regular identifier. It is often used to name “special” items, but it is not special to Python itself.

### Note

The name `_` is often used in conjunction with internationalization; refer to the documentation for the

[gettext](#) module for more information on this convention.

It is also commonly used for unused variables.

\_\_\*\_\_

System-defined names, informally known as “dunder” names. These names are defined by the interpreter and its implementation (including the standard library). Current system names are discussed in the [Special method names](#) section and elsewhere. More will likely be defined in future versions of Python. *Any* use of \_\_\*\_\_ names, in any context, that does not follow explicitly documented use, is subject to breakage without warning.

\_\_\*\_\_

Class-private names. Names in this category, when used within the context of a class definition, are re-written to use a mangled form to help avoid name clashes between “private” attributes of base and derived classes. See section [Identifiers \(Names\)](#).

## 2.4. Literals

Literals are notations for constant values of some built-in types.

### 2.4.1. String and Bytes literals

String literals are described by the following lexical definitions:

```
stringliteral ::= [stringprefix] (shortstring | longstring)
stringprefix ::= "r" | "u" | "R" | "U" | "f" | "F"
               | "fr" | "Fr" | "fR" | "FR" | "rf"
shortstring   ::= "'" shortstringitem* "'" | "'" shortstringitem* "'"
longstring    ::= '"' longstringitem* '"' | '"' longstringitem* '"'
shortstringitem ::= shortstringchar | stringescape
longstringitem  ::= longstringchar | stringescape
shortstringchar ::= <any source character except "\" or
```

```

longstringchar ::= <any source character except "\">
stringescapeseq ::= "\" <any source character>

bytesliteral ::= bytesprefix(shortbytes | longbytes)
bytesprefix ::= "b" | "B" | "br" | "Br" | "bR" | "BR"
shortbytes ::= "'" shortbytesitem* "'" | '"' shortbytesitem* '"'
longbytes ::= "'"'"' longbytesitem* "'"'"' | '"'""'"' longbytesitem* '"'""'"'
shortbytesitem ::= shortbyteschar | bytesescapeseq
longbytesitem ::= longbyteschar | bytesescapeseq
shortbyteschar ::= <any ASCII character except "\" or "\>
longbyteschar ::= <any ASCII character except "\">
bytesescapeseq ::= "\" <any ASCII character>

```

One syntactic restriction not indicated by these productions is that whitespace is not allowed between the **stringprefix** or **bytesprefix** and the rest of the literal. The source character set is defined by the encoding declaration; it is UTF-8 if no encoding declaration is given in the source file; see section [Encoding declarations](#).

In plain English: Both types of literals can be enclosed in matching single quotes (') or double quotes ("). They can also be enclosed in matching groups of three single or double quotes (these are generally referred to as *triple-quoted strings*). The backslash (\) character is used to escape characters that otherwise have a special meaning, such as newline, backslash itself, or the quote character.

Bytes literals are always prefixed with 'b' or 'B'; they produce an instance of the **bytes** type instead of the **str** type. They may only contain ASCII characters; bytes with a numeric value of 128 or greater must be expressed with escapes.

Both string and bytes literals may optionally be prefixed with a letter 'r' or 'R'; such strings are called *raw strings* and treat backslashes as literal characters. As a result, in string literals, '\u' and '\u' escapes in raw strings are not treated specially. Given that Python 2.x's raw unicode literals behave differently than Python 3.x's the 'ur' syntax is not supported.

*New in version 3.3:* The `'rb'` prefix of raw bytes literals has been added as a synonym of `'br'`.

*New in version 3.3:* Support for the unicode legacy literal (`'u'value'`) was reintroduced to simplify the maintenance of dual Python 2.x and 3.x codebases. See [PEP 414](https://peps.python.org/pep-0414/) [https://peps.python.org/pep-0414/] for more information.

A string literal with `'f'` or `'F'` in its prefix is a *formatted string literal*; see [Formatted string literals](#). The `'f'` may be combined with `'r'`, but not with `'b'` or `'u'`, therefore raw formatted strings are possible, but formatted bytes literals are not.

In triple-quoted literals, unescaped newlines and quotes are allowed (and are retained), except that three unescaped quotes in a row terminate the literal. (A “quote” is the character used to open the literal, i.e. either `'` or `"`.)

Unless an `'r'` or `'R'` prefix is present, escape sequences in string and bytes literals are interpreted according to rules similar to those used by Standard C. The recognized escape sequences are:

#### ~~Not a~~Escape sequence

---

~~Backslash~~ `\n` newline ignored

---

Backslash (`\`)

---

Single quote (`'`)

---

Double quote (`"`)

---

ASCII Bell (BEL)

---

ASCII Backspace (BS)

---

ASCII Formfeed (FF)

---

ASCII Linefeed (LF)

---

ASCII Carriage Return (CR)

---

ASCII Horizontal Tab (TAB)

---

ASCII Vertical Tab (VT)

---

~~Character~~ `\ooo` character with octal value *ooo*

---

~~Character~~ `\xhh` character with hex value *hh*

---

Escape sequences only recognized in string literals are:

#### ~~Not a~~Escape sequence

---

~~Character~~ `\N{name}` named *name* in the Unicode database

---

~~(b) Character with 16-bit hex value xxxx~~

~~(c) Character with 32-bit hex value xxxxxxxx~~

---

Notes:

1. A backslash can be added at the end of a line to ignore the newline:

```
>>> 'This string will not include \
... backslashes or newline characters.'
'This string will not include backslashes or newlin
```

The same result can be achieved using [triple-quoted strings](#), or parentheses and [string literal concatenation](#).

2. As in Standard C, up to three octal digits are accepted.

*Changed in version 3.11:* Octal escapes with value larger than 0o377 produce a [DeprecationWarning](#). In a future Python version they will be a [SyntaxWarning](#) and eventually a [SyntaxError](#).

3. Unlike in Standard C, exactly two hex digits are required.
4. In a bytes literal, hexadecimal and octal escapes denote the byte with the given value. In a string literal, these escapes denote a Unicode character with the given value.
5. *Changed in version 3.3:* Support for name aliases [1](#) has been added.
6. Exactly four hex digits are required.
7. Any Unicode character can be encoded this way. Exactly eight hex digits are required.

Unlike Standard C, all unrecognized escape sequences are left in the string unchanged, i.e., *the backslash is left in the result*. (This behavior is useful when debugging: if an escape sequence is mistyped, the resulting output is more easily recognized as broken.) It is also important to note that the escape sequences only recognized in string literals fall into the category of unrecognized

escapes for bytes literals.

*Changed in version 3.6:* Unrecognized escape sequences produce a **DeprecationWarning**. In a future Python version they will be a **SyntaxWarning** and eventually a **SyntaxError**.

Even in a raw literal, quotes can be escaped with a backslash, but the backslash remains in the result; for example, `r"\\"` is a valid string literal consisting of two characters: a backslash and a double quote; `r"\` is not a valid string literal (even a raw string cannot end in an odd number of backslashes). Specifically, *a raw literal cannot end in a single backslash* (since the backslash would escape the following quote character). Note also that a single backslash followed by a newline is interpreted as those two characters as part of the literal, *not* as a line continuation.

### 2.4.2. String literal concatenation

Multiple adjacent string or bytes literals (delimited by whitespace), possibly using different quoting conventions, are allowed, and their meaning is the same as their concatenation. Thus, `"hello"` `'world'` is equivalent to `"helloworld"`. This feature can be used to reduce the number of backslashes needed, to split long strings conveniently across long lines, or even to add comments to parts of strings, for example:

```
re.compile("[A-Za-z_]"          # letter or underscore
           "[A-Za-z0-9_]*"      # letter, digit or underscore
           )
```

Note that this feature is defined at the syntactical level, but implemented at compile time. The `+` operator must be used to concatenate string expressions at run time. Also note that literal concatenation can use different quoting styles for each component (even mixing raw strings and triple quoted strings), and formatted string literals may be concatenated with plain string literals.

### 2.4.3. Formatted string literals

*New in version 3.6.*

A *formatted string literal* or *f-string* is a string literal that is prefixed with 'f' or 'F'. These strings may contain replacement fields, which are expressions delimited by curly braces {}. While other string literals always have a constant value, formatted strings are really expressions evaluated at run time.

Escape sequences are decoded like in ordinary string literals (except when a literal is also marked as a raw string). After decoding, the grammar for the contents of the string is:

```

f_string ::= (literal_char | "{" | "}" | replacement
replacement_field ::= "{" f_expression ["="] ["!" conversion
f_expression ::= (conditional_expression | "*" or
    ("," conditional_expression | "
    | yield_expression
conversion ::= "s" | "r" | "a"
format_spec ::= (literal_char | NULL | replacement
literal_char ::= <any code point except "{", "}">

```

The parts of the string outside curly braces are treated literally, except that any doubled curly braces `'{{ ' or '}}`' are replaced with the corresponding single curly brace. A single opening curly bracket `'{'` marks a replacement field, which starts with a Python expression. To display both the expression text and its value after evaluation, (useful in debugging), an equal sign `'='` may be added after the expression. A conversion field, introduced by an exclamation point `'!'` may follow. A format specifier may also be appended, introduced by a colon `':'`. A replacement field ends with a closing curly bracket `'}'`.

Expressions in formatted string literals are treated like regular Python expressions surrounded by parentheses, with a few exceptions. An empty expression is not allowed, and both `lambda` and assignment expressions `:=` must be surrounded by explicit parentheses. Replacement expressions can contain line breaks (e.g. in triple-quoted strings), but they cannot contain comments. Each expression is evaluated in the context where the formatted string

literal appears, in order from left to right.

*Changed in version 3.7:* Prior to Python 3.7, an `await` expression and comprehensions containing an `async for` clause were illegal in the expressions in formatted string literals due to a problem with the implementation.

When the equal sign `'='` is provided, the output will have the expression text, the `'='` and the evaluated value. Spaces after the opening brace `'{'`, within the expression and after the `'='` are all retained in the output. By default, the `'='` causes the `repr()` of the expression to be provided, unless there is a format specified. When a format is specified it defaults to the `str()` of the expression unless a conversion `'!r'` is declared.

*New in version 3.8:* The equal sign `'='`.

If a conversion is specified, the result of evaluating the expression is converted before formatting. Conversion `'!s'` calls `str()` on the result, `'!r'` calls `repr()`, and `'!a'` calls `ascii()`.

The result is then formatted using the `format()` protocol. The format specifier is passed to the `__format__()` method of the expression or conversion result. An empty string is passed when the format specifier is omitted. The formatted result is then included in the final value of the whole string.

Top-level format specifiers may include nested replacement fields. These nested fields may include their own conversion fields and `format specifiers`, but may not include more deeply nested replacement fields. The `format specifier mini-language` is the same as that used by the `str.format()` method.

Formatted string literals may be concatenated, but replacement fields cannot be split across literals.

Some examples of formatted string literals:

```
>>> name = "Fred"
>>> f"He said his name is {name!r}."
"He said his name is 'Fred'."
```

```

>>> f"He said his name is {repr(name)}." # repr() is eq
"He said his name is 'Fred'."
>>> width = 10
>>> precision = 4
>>> value = decimal.Decimal("12.34567")
>>> f"result: {value:{width}.{precision}}" # nested fie
'result:      12.35'
>>> today = datetime(year=2017, month=1, day=27)
>>> f"{today:%B %d, %Y}" # using date format specifier
'January 27, 2017'
>>> f"{today=:%B %d, %Y}" # using date format specifier
'today=January 27, 2017'
>>> number = 1024
>>> f"{number:#0x}" # using integer format specifier
'0x400'
>>> foo = "bar"
>>> f"{ foo = }" # preserves whitespace
" foo = 'bar'"
>>> line = "The mill's closed"
>>> f"{line = }"
'line = "The mill\'s closed"'
>>> f"{line = :20}"
"line = The mill's closed    "
>>> f"{line = !r:20}"
'line = "The mill\'s closed" '

```

A consequence of sharing the same syntax as regular string literals is that characters in the replacement fields must not conflict with the quoting used in the outer formatted string literal:

```

f"abc {a["x"]} def" # error: outer string literal ends with "
f"abc {a['x']} def" # workaround: use different quoting

```

Backslashes are not allowed in format expressions and will raise an error:

```

f"newline: {ord('\n'))}" # raises SyntaxError

```

To include a value in which a backslash escape is required, create a temporary variable.

```
>>> newline = ord('\n')
>>> f"newline: {newline}"
'newline: 10'
```

Formatted string literals cannot be used as docstrings, even if they do not include expressions.

```
>>> def foo():
...     f"Not a docstring"
...
>>> foo.__doc__ is None
True
```

See also [PEP 498](https://peps.python.org/pep-0498/) [https://peps.python.org/pep-0498/] for the proposal that added formatted string literals, and `str.format()`, which uses a related format string mechanism.

## 2.4.4. Numeric literals

There are three types of numeric literals: integers, floating point numbers, and imaginary numbers. There are no complex literals (complex numbers can be formed by adding a real number and an imaginary number).

Note that numeric literals do not include a sign; a phrase like `-1` is actually an expression composed of the unary operator `'-'` and the literal `1`.

## 2.4.5. Integer literals

Integer literals are described by the following lexical definitions:

```
integer ::= decinteger | bininteger | octinteger |
decinteger ::= nonzerodigit (["_"] digit)* | "0"+ (["_"]
bininteger ::= "0" ("b" | "B") (["_"] bindigit)+
octinteger ::= "0" ("o" | "O") (["_"] octdigit)+
hexinteger ::= "0" ("x" | "X") (["_"] hexdigit)+
nonzerodigit ::= "1"..."9"
digit ::= "0"..."9"
```

```

bindigit      ::=  "0" | "1"
octdigit     ::=  "0"..."7"
hexdigit     ::=  digit | "a"..."f" | "A"..."F"

```

There is no limit for the length of integer literals apart from what can be stored in available memory.

Underscores are ignored for determining the numeric value of the literal. They can be used to group digits for enhanced readability. One underscore can occur between digits, and after base specifiers like `0x`.

Note that leading zeros in a non-zero decimal number are not allowed. This is for disambiguation with C-style octal literals, which Python used before version 3.0.

Some examples of integer literals:

```

7          2147483647          0o177      0b10011
3          79228162514264337593543950336  0o377      0xdeadb
          100_000_000_000          0b_1110_0101

```

*Changed in version 3.6:* Underscores are now allowed for grouping purposes in literals.

## 2.4.6. Floating point literals

Floating point literals are described by the following lexical definitions:

```

floatnumber  ::=  pointfloat | exponentfloat
pointfloat   ::=  [digitpart] fraction | digitpart "."
exponentfloat ::=  (digitpart | pointfloat) exponent
digitpart    ::=  digit ([ "_" ] digit) *
fraction     ::=  "." digitpart
exponent     ::=  ("e" | "E") [ "+" | "-" ] digitpart

```

Note that the integer and exponent parts are always interpreted using radix 10. For example, `077e010` is legal, and denotes the same number as `77e10`. The allowed range of floating point literals

is implementation-dependent. As in integer literals, underscores are supported for digit grouping.

Some examples of floating point literals:

3.14      10.      .001      1e100      3.14e-10      0e0      3.14\_

*Changed in version 3.6:* Underscores are now allowed for grouping purposes in literals.

### 2.4.7. Imaginary literals

Imaginary literals are described by the following lexical definitions:

**imagnumber** ::= (floatnumber | digitpart) ("j" | "J")

An imaginary literal yields a complex number with a real part of 0.0. Complex numbers are represented as a pair of floating point numbers and have the same restrictions on their range. To create a complex number with a nonzero real part, add a floating point number to it, e.g., (3+4j). Some examples of imaginary literals:

3.14j      10.j      10j      .001j      1e100j      3.14e-10j      3.1\_

## 2.5. Operators

The following tokens are operators:

+	-	*	**	/	//	%	@
<<	>>	&		^	~	:=	
<	>	<=	>=	==	!=		

## 2.6. Delimiters

The following tokens serve as delimiters in the grammar:

(	)	[	]	{	}		
,	:	.	;	@	=	->	
+=	-=	*=	/=	//=	%=	@=	

&=            | =            ^ =            >>=            <<=            \* \*=

The period can also occur in floating-point and imaginary literals. A sequence of three periods has a special meaning as an ellipsis literal. The second half of the list, the augmented assignment operators, serve lexically as delimiters, but also perform an operation.

The following printing ASCII characters have special meaning as part of other tokens or are otherwise significant to the lexical analyzer:

'            "            #            \

The following printing ASCII characters are not used in Python. Their occurrence outside string literals and comments is an unconditional error:

\$            ?            `

<https://www.unicode.org/Public/11.0.0/ucd/NameAliases.txt>

## 3. Data model

### 3.1. Objects, values and types

*Objects* are Python’s abstraction for data. All data in a Python program is represented by objects or by relations between objects. (In a sense, and in conformance to Von Neumann’s model of a “stored program computer”, code is also represented by objects.)

Every object has an identity, a type and a value. An object’s *identity* never changes once it has been created; you may think of it as the object’s address in memory. The `‘is’` operator compares the identity of two objects; the `id()` function returns an integer representing its identity.

**CPython implementation detail:** For CPython, `id(x)` is the memory address where `x` is stored.

An object’s type determines the operations that the object supports (e.g., “does it have a length?”) and also defines the possible values for objects of that type. The `type()` function returns an object’s type (which is an object itself). Like its identity, an object’s *type* is also unchangeable. [1](#)

The *value* of some objects can change. Objects whose value can change are said to be *mutable*; objects whose value is unchangeable once they are created are called *immutable*. (The value of an immutable container object that contains a reference to a mutable object can change when the latter’s value is changed; however the container is still considered immutable, because the collection of objects it contains cannot be changed. So, immutability is not strictly the same as having an unchangeable value, it is more subtle.) An object’s mutability is determined by its type; for instance, numbers, strings and tuples are immutable, while dictionaries and lists are mutable.

Objects are never explicitly destroyed; however, when they become unreachable they may be garbage-collected. An implementation is allowed to postpone garbage collection or omit it altogether — it is a matter of implementation quality how garbage collection is implemented, as long as no objects are collected that are still reachable.

**CPython implementation detail:** CPython currently uses a reference-counting scheme with (optional) delayed detection of cyclically linked garbage, which collects most objects as soon as they become unreachable, but is not guaranteed to collect garbage containing circular references. See the documentation of the `gc` module for information on controlling the collection of cyclic garbage. Other implementations act differently and CPython may change. Do not depend on immediate finalization of objects when they become unreachable (so you should always close files explicitly).

Note that the use of the implementation’s tracing or debugging facilities may keep objects alive that would normally be collectable. Also note that catching an exception with a `‘try...except’` statement may keep objects alive.

Some objects contain references to “external” resources such as open files or windows. It is understood that these resources are freed when the object is garbage-collected, but since garbage collection is not guaranteed to happen, such objects also provide an explicit way to release the external resource, usually a `close()` method. Programs are strongly recommended to explicitly close such objects. The `‘try...finally’` statement and the `‘with’` statement provide convenient ways to do this.

Some objects contain references to other objects; these are called *containers*. Examples of containers are tuples, lists and dictionaries. The references are part of a container’s value. In most cases, when we talk about the value of a container, we imply the values, not the identities of the contained objects; however, when we talk about the mutability of a container, only the identities of the immediately contained objects are implied. So, if an immutable container (like a tuple) contains a reference to a mutable object, its value changes if that mutable object is changed.

Types affect almost all aspects of object behavior. Even the importance of object identity is affected in some sense: for immutable types, operations that compute new values may actually return a reference to any existing object with the same type and value, while for mutable objects this is not allowed. E.g., after `a = 1; b = 1`, `a` and `b` may or may not refer to the same object with the value one, depending on the implementation, but after `c = []; d = []`, `c` and `d` are guaranteed to refer to two different, unique, newly created empty lists. (Note that `c = d = []` assigns the same object to both `c` and `d`.)

## 3.2. The standard type hierarchy

Below is a list of the types that are built into Python. Extension modules (written in C, Java, or other languages, depending on the implementation) can define additional types. Future versions of Python may add types to the type hierarchy (e.g., rational numbers, efficiently stored arrays of integers, etc.), although such additions will often be provided via the standard library instead.

Some of the type descriptions below contain a paragraph listing ‘special attributes.’ These are attributes that provide access to the implementation and are not intended for general use. Their definition may change in the future.

### None

This type has a single value. There is a single object with this value. This object is accessed through the built-in name `None`. It is used to signify the absence of a value in many situations, e.g., it is returned from functions that don’t explicitly return anything. Its truth value is false.

### NotImplemented

This type has a single value. There is a single object with this value. This object is accessed through the built-in name `NotImplemented`. Numeric methods and rich comparison methods should return this value if they do not implement the operation for the operands provided. (The interpreter will then try the reflected operation, or some other fallback,

depending on the operator.) It should not be evaluated in a boolean context.

See [Implementing the arithmetic operations](#) for more details.

*Changed in version 3.9:* Evaluating `NotImplemented` in a boolean context is deprecated. While it currently evaluates as true, it will emit a [DeprecationWarning](#). It will raise a [TypeError](#) in a future version of Python.

## Ellipsis

This type has a single value. There is a single object with this value. This object is accessed through the literal `...` or the built-in name `Ellipsis`. Its truth value is true.

## [numbers.Number](#)

These are created by numeric literals and returned as results by arithmetic operators and arithmetic built-in functions. Numeric objects are immutable; once created their value never changes. Python numbers are of course strongly related to mathematical numbers, but subject to the limitations of numerical representation in computers.

The string representations of the numeric classes, computed by [\\_\\_repr\\_\\_\(\)](#) and [\\_\\_str\\_\\_\(\)](#), have the following properties:

- They are valid numeric literals which, when passed to their class constructor, produce an object having the value of the original numeric.
- The representation is in base 10, when possible.
- Leading zeros, possibly excepting a single zero before a decimal point, are not shown.
- Trailing zeros, possibly excepting a single zero after a decimal point, are not shown.
- A sign is shown only when the number is negative.

Python distinguishes between integers, floating point numbers, and complex numbers:

## [numbers.Integral](#)

These represent elements from the mathematical set of integers (positive and negative).

There are two types of integers:

Integers (**int**)

These represent numbers in an unlimited range, subject to available (virtual) memory only. For the purpose of shift and mask operations, a binary representation is assumed, and negative numbers are represented in a variant of 2's complement which gives the illusion of an infinite string of sign bits extending to the left.

Booleans (**bool**)

These represent the truth values `False` and `True`. The two objects representing the values `False` and `True` are the only Boolean objects. The Boolean type is a subtype of the integer type, and Boolean values behave like the values 0 and 1, respectively, in almost all contexts, the exception being that when converted to a string, the strings `"False"` or `"True"` are returned, respectively.

The rules for integer representation are intended to give the most meaningful interpretation of shift and mask operations involving negative integers.

**numbers.Real** (**float**)

These represent machine-level double precision floating point numbers. You are at the mercy of the underlying machine architecture (and C or Java implementation) for the accepted range and handling of overflow. Python does not support single-precision floating point numbers; the savings in processor and memory usage that are usually the reason for using these are dwarfed by the overhead of using objects in Python, so there is no reason to complicate the language with two kinds of floating point numbers.

## `numbers.Complex (complex)`

These represent complex numbers as a pair of machine-level double precision floating point numbers. The same caveats apply as for floating point numbers. The real and imaginary parts of a complex number `z` can be retrieved through the read-only attributes `z.real` and `z.imag`.

## Sequences

These represent finite ordered sets indexed by non-negative numbers. The built-in function `len()` returns the number of items of a sequence. When the length of a sequence is  $n$ , the index set contains the numbers 0, 1, ...,  $n-1$ . Item  $i$  of sequence  $a$  is selected by `a[i]`.

Sequences also support slicing: `a[i:j]` selects all items with index  $k$  such that  $i \leq k < j$ . When used as an expression, a slice is a sequence of the same type. This implies that the index set is renumbered so that it starts at 0.

Some sequences also support “extended slicing” with a third “step” parameter: `a[i:j:k]` selects all items of  $a$  with index  $x$  where  $x = i + n*k$ ,  $n \geq 0$  and  $i \leq x < j$ .

Sequences are distinguished according to their mutability:

### Immutable sequences

An object of an immutable sequence type cannot change once it is created. (If the object contains references to other objects, these other objects may be mutable and may be changed; however, the collection of objects directly referenced by an immutable object cannot change.)

The following types are immutable sequences:

### Strings

A string is a sequence of values that represent Unicode code points. All the code points in the range `U+0000 - U+10FFFF` can be represented

in a string. Python doesn't have a char type; instead, every code point in the string is represented as a string object with length 1. The built-in function `ord()` converts a code point from its string form to an integer in the range 0 - 10FFFF; `chr()` converts an integer in the range 0 - 10FFFF to the corresponding length 1 string object. `str.encode()` can be used to convert a `str` to `bytes` using the given text encoding, and `bytes.decode()` can be used to achieve the opposite.

## Tuples

The items of a tuple are arbitrary Python objects. Tuples of two or more items are formed by comma-separated lists of expressions. A tuple of one item (a 'singleton') can be formed by affixing a comma to an expression (an expression by itself does not create a tuple, since parentheses must be usable for grouping of expressions). An empty tuple can be formed by an empty pair of parentheses.

## Bytes

A bytes object is an immutable array. The items are 8-bit bytes, represented by integers in the range  $0 \leq x < 256$ . Bytes literals (like `b'abc'`) and the built-in `bytes()` constructor can be used to create bytes objects. Also, bytes objects can be decoded to strings via the `decode()` method.

## Mutable sequences

Mutable sequences can be changed after they are created. The subscription and slicing notations can be used as the target of assignment and `del` (delete) statements.

There are currently two intrinsic mutable sequence types:

## Lists

The items of a list are arbitrary Python objects. Lists are formed by placing a comma-separated list of expressions in square brackets. (Note that there are no special cases needed to form lists of length 0 or 1.)

## Byte Arrays

A bytearray object is a mutable array. They are created by the built-in `bytearray()` constructor. Aside from being mutable (and hence unhashable), byte arrays otherwise provide the same interface and functionality as immutable `bytes` objects.

The extension module `array` provides an additional example of a mutable sequence type, as does the `collections` module.

## Set types

These represent unordered, finite sets of unique, immutable objects. As such, they cannot be indexed by any subscript. However, they can be iterated over, and the built-in function `len()` returns the number of items in a set. Common uses for sets are fast membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference.

For set elements, the same immutability rules apply as for dictionary keys. Note that numeric types obey the normal rules for numeric comparison: if two numbers compare equal (e.g., `1` and `1.0`), only one of them can be contained in a set.

There are currently two intrinsic set types:

### Sets

These represent a mutable set. They are created by the built-in `set()` constructor and can be modified

afterwards by several methods, such as `add()`.

### Frozen sets

These represent an immutable set. They are created by the built-in `frozenset()` constructor. As a frozenset is immutable and `hashable`, it can be used again as an element of another set, or as a dictionary key.

### Mappings

These represent finite sets of objects indexed by arbitrary index sets. The subscript notation `a[k]` selects the item indexed by `k` from the mapping `a`; this can be used in expressions and as the target of assignments or `del` statements. The built-in function `len()` returns the number of items in a mapping.

There is currently a single intrinsic mapping type:

### Dictionaries

These represent finite sets of objects indexed by nearly arbitrary values. The only types of values not acceptable as keys are values containing lists or dictionaries or other mutable types that are compared by value rather than by object identity, the reason being that the efficient implementation of dictionaries requires a key's hash value to remain constant. Numeric types used for keys obey the normal rules for numeric comparison: if two numbers compare equal (e.g., `1` and `1.0`) then they can be used interchangeably to index the same dictionary entry.

Dictionaries preserve insertion order, meaning that keys will be produced in the same order they were added sequentially over the dictionary. Replacing an existing key does not change the order, however removing a key and re-inserting it will add it to the end instead of keeping its old place.

Dictionaries are mutable; they can be created by the `{...}` notation (see section [Dictionary displays](#)).

The extension modules `dbm.ndbm` and `dbm.gnu` provide additional examples of mapping types, as does the `collections` module.

*Changed in version 3.7:* Dictionaries did not preserve insertion order in versions of Python before 3.6. In CPython 3.6, insertion order was preserved, but it was considered an implementation detail at that time rather than a language guarantee.

## Callable types

These are the types to which the function call operation (see section [Calls](#)) can be applied:

### User-defined functions

A user-defined function object is created by a function definition (see section [Function definitions](#)). It should be called with an argument list containing the same number of items as the function's formal parameter list.

Special attributes:

---

#### **\_\_doc\_\_**

The function's documentation string, or `None` if unavailable; not inherited by subclasses.

---

**\_\_name\_\_** The function's name.

---

**\_\_qualname\_\_** The function's qualified name.

---

*New in version 3.3.*

---

**\_\_module\_\_** The module the function was defined in, or `None` if unavailable.

---

**\_\_defaults\_\_** A tuple containing default argument values for those arguments that have defaults, or `None` if no arguments have a default value.

---

**\_\_code\_\_** The object representing the compiled function body.

---

**\_\_globals\_\_** A dictionary to the dictionary that holds the function's global variables — the global namespace of the module in which the function was defined.

---

**\_\_dict\_\_** A namespace supporting arbitrary function attributes.

---

**Read-only** tuple of cells that contain bindings for the function's free variables. See below for information on the `cell_contents` attribute.

---

**Annotations** annotations of parameters. The keys of the dict are the parameter names, and 'return' for the return annotation, if provided. For more information on working with this attribute, see [Annotations Best Practices](#).

---

**Defaults** defaults for keyword-only parameters.

---

Most of the attributes labelled “Writable” check the type of the assigned value.

Function objects also support getting and setting arbitrary attributes, which can be used, for example, to attach metadata to functions. Regular attribute dot-notation is used to get and set such attributes. *Note that the current implementation only supports function attributes on user-defined functions. Function attributes on built-in functions may be supported in the future.*

A cell object has the attribute `cell_contents`. This can be used to get the value of the cell, as well as set the value.

Additional information about a function's definition can be retrieved from its code object; see the description of internal types below. The `cell` type can be accessed in the `types` module.

## Instance methods

An instance method object combines a class, a class instance and any callable object (normally a user-defined function).

Special read-only attributes: `__self__` is the class instance object, `__func__` is the function object; `__doc__` is the method's documentation (same as `__func__.__doc__`); `__name__` is the method name (same as `__func__.__name__`); `__module__` is the

name of the module the method was defined in, or `None` if unavailable.

Methods also support accessing (but not setting) the arbitrary function attributes on the underlying function object.

User-defined method objects may be created when getting an attribute of a class (perhaps via an instance of that class), if that attribute is a user-defined function object or a class method object.

When an instance method object is created by retrieving a user-defined function object from a class via one of its instances, its `__self__` attribute is the instance, and the method object is said to be bound. The new method's `__func__` attribute is the original function object.

When an instance method object is created by retrieving a class method object from a class or instance, its `__self__` attribute is the class itself, and its `__func__` attribute is the function object underlying the class method.

When an instance method object is called, the underlying function (`__func__`) is called, inserting the class instance (`__self__`) in front of the argument list. For instance, when `C` is a class which contains a definition for a function `f()`, and `x` is an instance of `C`, calling `x.f(1)` is equivalent to calling `C.f(x, 1)`.

When an instance method object is derived from a class method object, the “class instance” stored in `__self__` will actually be the class itself, so that calling either `x.f(1)` or `C.f(1)` is equivalent to calling `f(C, 1)` where `f` is the underlying function.

Note that the transformation from function object to instance method object happens each time the attribute

is retrieved from the instance. In some cases, a fruitful optimization is to assign the attribute to a local variable and call that local variable. Also notice that this transformation only happens for user-defined functions; other callable objects (and all non-callable objects) are retrieved without transformation. It is also important to note that user-defined functions which are attributes of a class instance are not converted to bound methods; this *only* happens when the function is an attribute of the class.

### Generator functions

A function or method which uses the **yield** statement (see section [The yield statement](#)) is called a *generator function*. Such a function, when called, always returns an **iterator** object which can be used to execute the body of the function: calling the iterator's **iterator.\_\_next\_\_()** method will cause the function to execute until it provides a value using the **yield** statement. When the function executes a **return** statement or falls off the end, a **StopIteration** exception is raised and the iterator will have reached the end of the set of values to be returned.

### Coroutine functions

A function or method which is defined using **async def** is called a *coroutine function*. Such a function, when called, returns a **coroutine** object. It may contain **await** expressions, as well as **async with** and **async for** statements. See also the [Coroutine Objects](#) section.

### Asynchronous generator functions

A function or method which is defined using **async def** and which uses the **yield** statement is called a *asynchronous generator function*. Such a function, when called, returns an **asynchronous iterator** object which can be used in an **async for** statement to execute the body of the function.

Calling the asynchronous iterator's `iterator.__anext__` method will return an `awaitable` which when awaited will execute until it provides a value using the `yield` expression. When the function executes an empty `return` statement or falls off the end, a `StopAsyncIteration` exception is raised and the asynchronous iterator will have reached the end of the set of values to be yielded.

## Built-in functions

A built-in function object is a wrapper around a C function. Examples of built-in functions are `len()` and `math.sin()` (`math` is a standard built-in module). The number and type of the arguments are determined by the C function. Special read-only attributes: `__doc__` is the function's documentation string, or `None` if unavailable; `__name__` is the function's name; `__self__` is set to `None` (but see the next item); `__module__` is the name of the module the function was defined in or `None` if unavailable.

## Built-in methods

This is really a different disguise of a built-in function, this time containing an object passed to the C function as an implicit extra argument. An example of a built-in method is `alist.append()`, assuming `alist` is a list object. In this case, the special read-only attribute `__self__` is set to the object denoted by `alist`.

## Classes

Classes are callable. These objects normally act as factories for new instances of themselves, but variations are possible for class types that override `__new__()`. The arguments of the call are passed to `__new__()` and, in the typical case, to `__init__()` to initialize the new instance.

## Class Instances

Instances of arbitrary classes can be made callable by defining a `__call__()` method in their class.

## Modules

Modules are a basic organizational unit of Python code, and are created by the [import system](#) as invoked either by the [import](#) statement, or by calling functions such as [importlib.import\\_module\(\)](#) and built-in [\\_\\_import\\_\\_\(\)](#). A module object has a namespace implemented by a dictionary object (this is the dictionary referenced by the `__globals__` attribute of functions defined in the module). Attribute references are translated to lookups in this dictionary, e.g., `m.x` is equivalent to `m.__dict__["x"]`. A module object does not contain the code object used to initialize the module (since it isn't needed once the initialization is done).

Attribute assignment updates the module's namespace dictionary, e.g., `m.x = 1` is equivalent to `m.__dict__["x"] = 1`.

Predefined (writable) attributes:

[\\_\\_name\\_\\_](#)

The module's name.

[\\_\\_doc\\_\\_](#)

The module's documentation string, or None if unavailable.

[\\_\\_file\\_\\_](#)

The pathname of the file from which the module was loaded, if it was loaded from a file. The [\\_\\_file\\_\\_](#) attribute may be missing for certain types of modules, such as C modules that are statically linked into the interpreter. For extension modules loaded dynamically from a shared library, it's the pathname of the shared library file.

[\\_\\_annotations\\_\\_](#)

A dictionary containing [variable](#)

[annotations](#) collected during module body execution. For best practices on working with `__annotations__`, please see [Annotations Best Practices](#).

Special read-only attribute: `__dict__` is the module's namespace as a dictionary object.

**CPython implementation detail:** Because of the way CPython clears module dictionaries, the module dictionary will be cleared when the module falls out of scope even if the dictionary still has live references. To avoid this, copy the dictionary or keep the module around while using its dictionary directly.

## Custom classes

Custom class types are typically created by class definitions (see section [Class definitions](#)). A class has a namespace implemented by a dictionary object. Class attribute references are translated to lookups in this dictionary, e.g., `C.x` is translated to `C.__dict__["x"]` (although there are a number of hooks which allow for other means of locating attributes). When the attribute name is not found there, the attribute search continues in the base classes. This search of the base classes uses the C3 method resolution order which behaves correctly even in the presence of ‘diamond’ inheritance structures where there are multiple inheritance paths leading back to a common ancestor. Additional details on the C3 MRO used by Python can be found in the documentation accompanying the 2.3 release at <https://www.python.org/download/releases/2.3/mro/>.

When a class attribute reference (for class `C`, say) would yield a class method object, it is transformed into an instance method object whose `__self__` attribute is `C`. When it would yield a static method object, it is transformed into the object wrapped by the static method object. See section [Implementing Descriptors](#) for another way in which attributes retrieved from a class may differ from those actually contained in its `__dict__`.

Class attribute assignments update the class's dictionary, never the dictionary of a base class.

A class object can be called (see above) to yield a class instance (see below).

Special attributes:

[\\_\\_name\\_\\_](#)

The class name.

[\\_\\_module\\_\\_](#)

The name of the module in which the class was defined.

[\\_\\_dict\\_\\_](#)

The dictionary containing the class's namespace.

[\\_\\_bases\\_\\_](#)

A tuple containing the base classes, in the order of their occurrence in the base class list.

[\\_\\_doc\\_\\_](#)

The class's documentation string, or `None` if undefined.

[\\_\\_annotations\\_\\_](#)

A dictionary containing [variable annotations](#) collected during class body execution. For best practices on working with [\\_\\_annotations\\_\\_](#), please see [Annotations Best Practices](#).

## Class instances

A class instance is created by calling a class object (see above). A class instance has a namespace implemented as a dictionary which is the first place in which attribute references are searched. When an attribute is not found there, and the instance's class has an attribute by that name, the

search continues with the class attributes. If a class attribute is found that is a user-defined function object, it is transformed into an instance method object whose `__self__` attribute is the instance. Static method and class method objects are also transformed; see above under “Classes”. See section [Implementing Descriptors](#) for another way in which attributes of a class retrieved via its instances may differ from the objects actually stored in the class’s `__dict__`. If no class attribute is found, and the object’s class has a `__getattr__()` method, that is called to satisfy the lookup.

Attribute assignments and deletions update the instance’s dictionary, never a class’s dictionary. If the class has a `__setattr__()` or `__delattr__()` method, this is called instead of updating the instance dictionary directly.

Class instances can pretend to be numbers, sequences, or mappings if they have methods with certain special names. See section [Special method names](#).

Special attributes: `__dict__` is the attribute dictionary; `__class__` is the instance’s class.

I/O objects (also known as file objects)

A [file object](#) represents an open file. Various shortcuts are available to create file objects: the `open()` built-in function, and also `os.popen()`, `os.fdopen()`, and the `makefile()` method of socket objects (and perhaps by other functions or methods provided by extension modules).

The objects `sys.stdin`, `sys.stdout` and `sys.stderr` are initialized to file objects corresponding to the interpreter’s standard input, output and error streams; they are all open in text mode and therefore follow the interface defined by the [io.TextIOBase](#) abstract class.

Internal types

A few types used internally by the interpreter are exposed to the user. Their definitions may change with future versions of

the interpreter, but they are mentioned here for completeness.

## Code objects

Code objects represent *byte-compiled* executable Python code, or [bytecode](#). The difference between a code object and a function object is that the function object contains an explicit reference to the function's globals (the module in which it was defined), while a code object contains no context; also the default argument values are stored in the function object, not in the code object (because they represent values calculated at run-time). Unlike function objects, code objects are immutable and contain no references (directly or indirectly) to mutable objects.

Special read-only attributes: **co\_name** gives the function name; **co\_qualname** gives the fully qualified function name; **co\_argcount** is the total number of positional arguments (including positional-only arguments and arguments with default values); **co\_posonlyargcount** is the number of positional-only arguments (including arguments with default values); **co\_kwonlyargcount** is the number of keyword-only arguments (including arguments with default values); **co\_nlocals** is the number of local variables used by the function (including arguments); **co\_varnames** is a tuple containing the names of the local variables (starting with the argument names); **co\_cellvars** is a tuple containing the names of local variables that are referenced by nested functions; **co\_freevars** is a tuple containing the names of free variables; **co\_code** is a string representing the sequence of bytecode instructions; **co\_consts** is a tuple containing the literals used by the bytecode; **co\_names** is a tuple containing the names used by the bytecode; **co\_filename** is the filename from which the code was compiled; **co\_firstlineno** is the first line number of the function; **co\_lnotab** is a string encoding the mapping from bytecode offsets to line

numbers (for details see the source code of the interpreter); **co\_stacksize** is the required stack size; **co\_flags** is an integer encoding a number of flags for the interpreter.

The following flag bits are defined for **co\_flags**: bit 0x04 is set if the function uses the `*arguments` syntax to accept an arbitrary number of positional arguments; bit 0x08 is set if the function uses the `**keywords` syntax to accept arbitrary keyword arguments; bit 0x20 is set if the function is a generator.

Future feature declarations (from `__future__` import `division`) also use bits in **co\_flags** to indicate whether a code object was compiled with a particular feature enabled: bit 0x2000 is set if the function was compiled with future division enabled; bits 0x10 and 0x1000 were used in earlier versions of Python.

Other bits in **co\_flags** are reserved for internal use.

If a code object represents a function, the first item in **co\_consts** is the documentation string of the function, or `None` if undefined.

`codeobject.co_positions()`

Returns an iterable over the source code positions of each bytecode instruction in the code object.

The iterator returns tuples containing the `(start_line, end_line, start_column, end_column)`. The *i*-th tuple corresponds to the position of the source code that compiled to the *i*-th instruction. Column information is 0-indexed utf-8 byte offsets on the given source line.

This positional information can be missing. A non-exhaustive lists of cases where this may happen:

- Running the interpreter with `-X no_debug_ranges`.
- Loading a pyc file compiled while using `-X no_debug_ranges`.
- Position tuples corresponding to artificial instructions.
- Line and column numbers that can't be represented due to implementation specific limitations.

When this occurs, some or all of the tuple elements can be `None`.

*New in version 3.11.*

### Note

This feature requires storing column positions in code objects which may result in a small increase of disk usage of compiled Python files or interpreter memory usage. To avoid storing the extra information and/or deactivate printing the extra traceback information, the `-X no_debug_ranges` command line flag or the `PYTHONNODEBUGRANGES` environment variable can be used.

## Frame objects

Frame objects represent execution frames. They may occur in traceback objects (see below), and are also passed to registered trace functions.

Special read-only attributes: `f_back` is to the previous stack frame (towards the caller), or `None` if this is the bottom stack frame; `f_code` is the code object being executed in this frame; `f_locals` is the dictionary used to look up local variables; `f_globals` is used for global variables; `f_builtins` is used for built-in (intrinsic) names; `f_lasti` gives the precise

instruction (this is an index into the bytecode string of the code object).

Accessing `f_code` raises an [auditing event](#) `object.__getattr__` with arguments `obj` and `"f_code"`.

Special writable attributes: **`f_trace`**, if not `None`, is a function called for various events during code execution (this is used by the debugger). Normally an event is triggered for each new source line - this can be disabled by setting **`f_trace_lines`** to **`False`**.

Implementations *may* allow per-opcode events to be requested by setting **`f_trace_opcodes`** to **`True`**. Note that this may lead to undefined interpreter behaviour if exceptions raised by the trace function escape to the function being traced.

**`f_lineno`** is the current line number of the frame — writing to this from within a trace function jumps to the given line (only for the bottom-most frame). A debugger can implement a Jump command (aka Set Next Statement) by writing to `f_lineno`.

Frame objects support one method:

`frame.clear()`

This method clears all references to local variables held by the frame. Also, if the frame belonged to a generator, the generator is finalized. This helps break reference cycles involving frame objects (for example when catching an exception and storing its traceback for later use).

**`RuntimeError`** is raised if the frame is currently executing.

*New in version 3.4.*

## Traceback objects

Traceback objects represent a stack trace of an exception. A traceback object is implicitly created when an exception occurs, and may also be explicitly created by calling `types.TracebackType`.

For implicitly created tracebacks, when the search for an exception handler unwinds the execution stack, at each unwound level a traceback object is inserted in front of the current traceback. When an exception handler is entered, the stack trace is made available to the program. (See section [The try statement](#).) It is accessible as the third item of the tuple returned by `sys.exc_info()`, and as the `__traceback__` attribute of the caught exception.

When the program contains no suitable handler, the stack trace is written (nicely formatted) to the standard error stream; if the interpreter is interactive, it is also made available to the user as `sys.last_traceback`.

For explicitly created tracebacks, it is up to the creator of the traceback to determine how the `tb_next` attributes should be linked to form a full stack trace.

Special read-only attributes: `tb_frame` points to the execution frame of the current level; `tb_lineno` gives the line number where the exception occurred; `tb_lasti` indicates the precise instruction. The line number and last instruction in the traceback may differ from the line number of its frame object if the exception occurred in a `try` statement with no matching except clause or with a finally clause.

Accessing `tb_frame` raises an [auditing event](#) object.`__getattr__` with arguments `obj` and `"tb_frame"`.

Special writable attribute: `tb_next` is the next level in the stack trace (towards the frame where the exception occurred), or `None` if there is no next level.

*Changed in version 3.7:* Traceback objects can now be explicitly instantiated from Python code, and the `tb_next` attribute of existing instances can be updated.

## Slice objects

Slice objects are used to represent slices for `__getitem__()` methods. They are also created by the built-in `slice()` function.

Special read-only attributes: **start** is the lower bound; **stop** is the upper bound; **step** is the step value; each is `None` if omitted. These attributes can have any type.

Slice objects support one method:

`slice.indices(self, length)`

This method takes a single integer argument *length* and computes information about the slice that the slice object would describe if applied to a sequence of *length* items. It returns a tuple of three integers; respectively these are the *start* and *stop* indices and the *step* or stride length of the slice. Missing or out-of-bounds indices are handled in a manner consistent with regular slices.

## Static method objects

Static method objects provide a way of defeating the transformation of function objects to method objects described above. A static method object is a wrapper around any other object, usually a user-defined method object. When a static method object is retrieved from a class or a class instance, the object actually returned is the wrapped object, which is not subject to any further transformation. Static method objects are also callable. Static method objects are created by the built-in `staticmethod()` constructor.

## Class method objects

A class method object, like a static method object, is a wrapper around another object that alters the way in which that object is retrieved from classes and class instances. The behaviour of class method objects upon such retrieval is described above, under “User-defined methods”. Class method objects are created by the built-in `classmethod()` constructor.

## 3.3. Special method names

A class can implement certain operations that are invoked by special syntax (such as arithmetic operations or subscripting and slicing) by defining methods with special names. This is Python’s approach to *operator overloading*, allowing classes to define their own behavior with respect to language operators. For instance, if a class defines a method named `__getitem__()`, and `x` is an instance of this class, then `x[i]` is roughly equivalent to `type(x).__getitem__(x, i)`. Except where mentioned, attempts to execute an operation raise an exception when no appropriate method is defined (typically `AttributeError` or `TypeError`).

Setting a special method to `None` indicates that the corresponding operation is not available. For example, if a class sets `__iter__()` to `None`, the class is not iterable, so calling `iter()` on its instances will raise a `TypeError` (without falling back to `__getitem__()`). 2

When implementing a class that emulates any built-in type, it is important that the emulation only be implemented to the degree that it makes sense for the object being modelled. For example, some sequences may work well with retrieval of individual elements, but extracting a slice may not make sense. (One example of this is the `NodeList` interface in the W3C’s Document Object Model.)

### 3.3.1. Basic customization

`object._new_(cls[, ...])`

Called to create a new instance of class *cls*. `__new__()` is a static method (special-cased so you need not declare it as such) that takes the class of which an instance was requested as its first argument. The remaining arguments are those passed to the object constructor expression (the call to the class). The return value of `__new__()` should be the new object instance (usually an instance of *cls*).

Typical implementations create a new instance of the class by invoking the superclass's `__new__()` method using `super().__new__(cls[, ...])` with appropriate arguments and then modifying the newly created instance as necessary before returning it.

If `__new__()` is invoked during object construction and it returns an instance of *cls*, then the new instance's `__init__()` method will be invoked like `__init__(self[, ...])`, where *self* is the new instance and the remaining arguments are the same as were passed to the object constructor.

If `__new__()` does not return an instance of *cls*, then the new instance's `__init__()` method will not be invoked.

`__new__()` is intended mainly to allow subclasses of immutable types (like int, str, or tuple) to customize instance creation. It is also commonly overridden in custom metaclasses in order to customize class creation.

`object.__init__(self[, ...])`

Called after the instance has been created (by `__new__()`), but before it is returned to the caller. The arguments are those passed to the class constructor expression. If a base class has an `__init__()` method, the derived class's `__init__()` method, if any, must explicitly call it to ensure proper initialization of the base class part of the instance; for example: `super().__init__([args...])`.

Because `__new__()` and `__init__()` work together in constructing objects (`__new__()` to create it, and

`__init__()` to customize it), no non-None value may be returned by `__init__()`; doing so will cause a `TypeError` to be raised at runtime.

### `object.__del__(self)`

Called when the instance is about to be destroyed. This is also called a finalizer or (improperly) a destructor. If a base class has a `__del__()` method, the derived class's `__del__()` method, if any, must explicitly call it to ensure proper deletion of the base class part of the instance.

It is possible (though not recommended!) for the `__del__()` method to postpone destruction of the instance by creating a new reference to it. This is called object *resurrection*. It is implementation-dependent whether `__del__()` is called a second time when a resurrected object is about to be destroyed; the current CPython implementation only calls it once.

It is not guaranteed that `__del__()` methods are called for objects that still exist when the interpreter exits.

### Note

`del x` doesn't directly call `x.__del__()` — the former decrements the reference count for `x` by one, and the latter is only called when `x`'s reference count reaches zero.

**CPython implementation detail:** It is possible for a reference cycle to prevent the reference count of an object from going to zero. In this case, the cycle will be later detected and deleted by the `cyclic garbage collector`. A common cause of reference cycles is when an exception has been caught in a local variable. The frame's locals then reference the exception, which references its own traceback, which references the locals of all frames caught in the traceback.

### See also

Documentation for the `gc` module.

## Warning

Due to the precarious circumstances under which `__del__()` methods are invoked, exceptions that occur during their execution are ignored, and a warning is printed to `sys.stderr` instead. In particular:

- `__del__()` can be invoked when arbitrary code is being executed, including from any arbitrary thread. If `__del__()` needs to take a lock or invoke any other blocking resource, it may deadlock as the resource may already be taken by the code that gets interrupted to execute `__del__()`.
- `__del__()` can be executed during interpreter shutdown. As a consequence, the global variables it needs to access (including other modules) may already have been deleted or set to `None`. Python guarantees that globals whose name begins with a single underscore are deleted from their module before other globals are deleted; if no other references to such globals exist, this may help in assuring that imported modules are still available at the time when the `__del__()` method is called.

`object.__repr__(self)`

Called by the `repr()` built-in function to compute the “official” string representation of an object. If at all possible, this should look like a valid Python expression that could be used to recreate an object with the same value (given an appropriate environment). If this is not possible, a string of the form `<...some useful description...>` should be returned. The return value must be a string object. If a class defines `__repr__()` but not `__str__()`, then `__repr__()` is also used when an “informal” string

representation of instances of that class is required.

This is typically used for debugging, so it is important that the representation is information-rich and unambiguous.

`object.__str__(self)`

Called by `str(object)` and the built-in functions `format()` and `print()` to compute the “informal” or nicely printable string representation of an object. The return value must be a `string` object.

This method differs from `object.__repr__()` in that there is no expectation that `__str__()` return a valid Python expression: a more convenient or concise representation can be used.

The default implementation defined by the built-in type `object` calls `object.__repr__()`.

`object.__bytes__(self)`

Called by `bytes` to compute a byte-string representation of an object. This should return a `bytes` object.

`object.__format__(self, format_spec)`

Called by the `format()` built-in function, and by extension, evaluation of `formatted string literals` and the `str.format()` method, to produce a “formatted” string representation of an object. The `format_spec` argument is a string that contains a description of the formatting options desired. The interpretation of the `format_spec` argument is up to the type implementing `__format__()`, however most classes will either delegate formatting to one of the built-in types, or use a similar formatting option syntax.

See [Format Specification Mini-Language](#) for a description of

the standard formatting syntax.

The return value must be a string object.

*Changed in version 3.4:* The `__format__` method of `object` itself raises a `TypeError` if passed any non-empty string.

*Changed in version 3.7:* `object.__format__(x, '')` is now equivalent to `str(x)` rather than `format(str(x), '')`.

`object.__lt__(self, other)`

`object.__le__(self, other)`

`object.__eq__(self, other)`

`object.__ne__(self, other)`

`object.__gt__(self, other)`

`object.__ge__(self, other)`

These are the so-called “rich comparison” methods. The correspondence between operator symbols and method names is as follows: `x < y` calls `x.__lt__(y)`, `x <= y` calls `x.__le__(y)`, `x == y` calls `x.__eq__(y)`, `x != y` calls `x.__ne__(y)`, `x > y` calls `x.__gt__(y)`, and `x >= y` calls `x.__ge__(y)`.

A rich comparison method may return the singleton `NotImplemented` if it does not implement the operation for a given pair of arguments. By convention, `False` and `True` are returned for a successful comparison. However, these methods can return any value, so if the comparison operator is used in a Boolean context (e.g., in the condition of an `if` statement), Python will call `bool()` on the value to determine if the result is true or false.

By default, `object` implements `__eq__()` by using `is`, returning `NotImplemented` in the case of a false comparison: `True if x is y else NotImplemented`. For `__ne__()`, by default it delegates to `__eq__()` and inverts the result unless it is `NotImplemented`. There are no other implied relationships among the comparison

operators or default implementations; for example, the truth of  $(x < y \text{ or } x == y)$  does not imply  $x \leq y$ . To automatically generate ordering operations from a single root operation, see `functools.total_ordering()`.

See the paragraph on `__hash__()` for some important notes on creating `hashable` objects which support custom comparison operations and are usable as dictionary keys.

There are no swapped-argument versions of these methods (to be used when the left argument does not support the operation but the right argument does); rather, `__lt__()` and `__gt__()` are each other's reflection, `__le__()` and `__ge__()` are each other's reflection, and `__eq__()` and `__ne__()` are their own reflection. If the operands are of different types, and right operand's type is a direct or indirect subclass of the left operand's type, the reflected method of the right operand has priority, otherwise the left operand's method has priority. Virtual subclassing is not considered.

`object.__hash__(self)`

Called by built-in function `hash()` and for operations on members of hashed collections including `set`, `frozenset`, and `dict`. The `__hash__()` method should return an integer. The only required property is that objects which compare equal have the same hash value; it is advised to mix together the hash values of the components of the object that also play a part in comparison of objects by packing them into a tuple and hashing the tuple. Example:

```
def __hash__(self):
    return hash((self.name, self.nick, self.color))
```

### Note

`hash()` truncates the value returned from an object's custom `__hash__()` method to the size of a `Py_ssize_t`. This is typically 8 bytes on 64-bit builds and 4 bytes on 32-bit builds. If an object's `__hash__()` must interoperate on builds of different bit sizes, be sure to

check the width on all supported builds. An easy way to do this is with `python -c "import sys; print(sys.hash_info.width)"`.

If a class does not define an `__eq__()` method it should not define a `__hash__()` operation either; if it defines `__eq__()` but not `__hash__()`, its instances will not be usable as items in hashable collections. If a class defines mutable objects and implements an `__eq__()` method, it should not implement `__hash__()`, since the implementation of hashable collections requires that a key's hash value is immutable (if the object's hash value changes, it will be in the wrong hash bucket).

User-defined classes have `__eq__()` and `__hash__()` methods by default; with them, all objects compare unequal (except with themselves) and `x.__hash__()` returns an appropriate value such that `x == y` implies both that `x is y` and `hash(x) == hash(y)`.

A class that overrides `__eq__()` and does not define `__hash__()` will have its `__hash__()` implicitly set to `None`. When the `__hash__()` method of a class is `None`, instances of the class will raise an appropriate `TypeError` when a program attempts to retrieve their hash value, and will also be correctly identified as unhashable when checking `isinstance(obj, collections.abc.Hashable)`.

If a class that overrides `__eq__()` needs to retain the implementation of `__hash__()` from a parent class, the interpreter must be told this explicitly by setting `__hash__ = <ParentClass>.__hash__`.

If a class that does not override `__eq__()` wishes to suppress hash support, it should include `__hash__ = None` in the class definition. A class which defines its own `__hash__()` that explicitly raises a `TypeError` would be incorrectly identified as hashable by an `isinstance(obj, collections.abc.Hashable)` call.

## Note

By default, the `__hash__()` values of str and bytes objects are “salted” with an unpredictable random value. Although they remain constant within an individual Python process, they are not predictable between repeated invocations of Python.

This is intended to provide protection against a denial-of-service caused by carefully chosen inputs that exploit the worst case performance of a dict insertion,  $O(n^2)$  complexity. See <http://ocert.org/advisories/ocert-2011-003.html> for details.

Changing hash values affects the iteration order of sets. Python has never made guarantees about this ordering (and it typically varies between 32-bit and 64-bit builds).

See also `PYTHONHASHSEED`.

*Changed in version 3.3:* Hash randomization is enabled by default.

`object.__bool__(self)`

Called to implement truth value testing and the built-in operation `bool()`; should return `False` or `True`. When this method is not defined, `__len__()` is called, if it is defined, and the object is considered true if its result is nonzero. If a class defines neither `__len__()` nor `__bool__()`, all its instances are considered true.

### 3.3.2. Customizing attribute access

The following methods can be defined to customize the meaning of attribute access (use of, assignment to, or deletion of `x.name`) for class instances.

`object.__getattr__(self, name)`

Called when the default attribute access fails with an `AttributeError` (either `__getattribute__()` raises an

**AttributeError** because *name* is not an instance attribute or an attribute in the class tree for `self`; or `__get__()` of a *name* property raises **AttributeError**). This method should either return the (computed) attribute value or raise an **AttributeError** exception.

Note that if the attribute is found through the normal mechanism, `__getattr__()` is not called. (This is an intentional asymmetry between `__getattr__()` and `__setattr__()`.) This is done both for efficiency reasons and because otherwise `__getattr__()` would have no way to access other attributes of the instance. Note that at least for instance variables, you can fake total control by not inserting any values in the instance attribute dictionary (but instead inserting them in another object). See the `__getattribute__()` method below for a way to actually get total control over attribute access.

`object.__getattribute__(self, name)`

Called unconditionally to implement attribute accesses for instances of the class. If the class also defines `__getattr__()`, the latter will not be called unless `__getattribute__()` either calls it explicitly or raises an **AttributeError**. This method should return the (computed) attribute value or raise an **AttributeError** exception. In order to avoid infinite recursion in this method, its implementation should always call the base class method with the same name to access any attributes it needs, for example, `object.__getattribute__(self, name)`.

### Note

This method may still be bypassed when looking up special methods as the result of implicit invocation via language syntax or built-in functions. See [Special method lookup](#).

For certain sensitive attribute accesses, raises an **auditing event** object `object.__getattr__` with arguments `obj` and `name`.

`object.__setattr__(self, name, value)`

Called when an attribute assignment is attempted. This is called instead of the normal mechanism (i.e. store the value in the instance dictionary). *name* is the attribute name, *value* is the value to be assigned to it.

If `__setattr__()` wants to assign to an instance attribute, it should call the base class method with the same name, for example, `object.__setattr__(self, name, value)`.

For certain sensitive attribute assignments, raises an [auditing event](#) `object.__setattr__` with arguments `obj`, `name`, `value`.

`object.__delattr__(self, name)`

Like `__setattr__()` but for attribute deletion instead of assignment. This should only be implemented if `del obj.name` is meaningful for the object.

For certain sensitive attribute deletions, raises an [auditing event](#) `object.__delattr__` with arguments `obj` and `name`.

`object.__dir__(self)`

Called when `dir()` is called on the object. A sequence must be returned. `dir()` converts the returned sequence to a list and sorts it.

### 3.3.2.1. Customizing module attribute access

Special names `__getattr__` and `__dir__` can be also used to customize access to module attributes. The `__getattr__` function at the module level should accept one argument which is the name of an attribute and return the computed value or raise an [AttributeError](#). If an attribute is not found on a module object through the normal lookup, i.e. `object.__getattribute__()`, then `__getattr__` is searched in the module `__dict__` before raising an [AttributeError](#). If found, it is called with the attribute name and the result is returned.

The `__dir__` function should accept no arguments, and return a sequence of strings that represents the names accessible on module. If present, this function overrides the standard `dir()` search on a module.

For a more fine grained customization of the module behavior (setting attributes, properties, etc.), one can set the `__class__` attribute of a module object to a subclass of `types.ModuleType`. For example:

```
import sys
from types import ModuleType

class VerboseModule(ModuleType):
    def __repr__(self):
        return f'Verbose {self.__name__}'

    def __setattr__(self, attr, value):
        print(f'Setting {attr}...')
        super().__setattr__(attr, value)

sys.modules[__name__].__class__ = VerboseModule
```

## Note

Defining module `__getattr__` and setting module `__class__` only affect lookups made using the attribute access syntax – directly accessing the module globals (whether by code within the module, or via a reference to the module’s globals dictionary) is unaffected.

*Changed in version 3.5:* `__class__` module attribute is now writable.

*New in version 3.7:* `__getattr__` and `__dir__` module attributes.

### PEP 562 [<https://peps.python.org/pep-0562/>] - Module `__getattr__` and `__dir__`

Describes the `__getattr__` and `__dir__` functions on modules.

#### 3.3.2.2. Implementing Descriptors

The following methods only apply when an instance of the class containing the method (a so-called *descriptor* class) appears in an *owner* class (the descriptor must be in either the owner's class dictionary or in the class dictionary for one of its parents). In the examples below, “the attribute” refers to the attribute whose name is the key of the property in the owner class’ `__dict__`.

`object.__get__(self, instance, owner=None)`

Called to get the attribute of the owner class (class attribute access) or of an instance of that class (instance attribute access). The optional *owner* argument is the owner class, while *instance* is the instance that the attribute was accessed through, or `None` when the attribute is accessed through the *owner*.

This method should return the computed attribute value or raise an `AttributeError` exception.

PEP 252 [<https://peps.python.org/pep-0252/>] specifies that `__get__()` is callable with one or two arguments. Python's own built-in descriptors support this specification; however, it is likely that some third-party tools have descriptors that require both arguments. Python's own `__getattribute__()` implementation always passes in both arguments whether they are required or not.

`object.__set__(self, instance, value)`

Called to set the attribute on an instance *instance* of the owner class to a new value, *value*.

Note, adding `__set__()` or `__delete__()` changes the kind of descriptor to a “data descriptor”. See [Invoking](#)

[Descriptors](#) for more details.

`object._delete_(self, instance)`

Called to delete the attribute on an instance *instance* of the owner class.

The attribute `__objclass__` is interpreted by the [inspect](#) module as specifying the class where this object was defined (setting this appropriately can assist in runtime introspection of dynamic class attributes). For callables, it may indicate that an instance of the given type (or a subclass) is expected or required as the first positional argument (for example, CPython sets this attribute for unbound methods that are implemented in C).

### 3.3.2.3. Invoking Descriptors

In general, a descriptor is an object attribute with “binding behavior”, one whose attribute access has been overridden by methods in the descriptor protocol: `__get__()`, `__set__()`, and `__delete__()`. If any of those methods are defined for an object, it is said to be a descriptor.

The default behavior for attribute access is to get, set, or delete the attribute from an object’s dictionary. For instance, `a.x` has a lookup chain starting with `a.__dict__['x']`, then `type(a).__dict__['x']`, and continuing through the base classes of `type(a)` excluding metaclasses.

However, if the looked-up value is an object defining one of the descriptor methods, then Python may override the default behavior and invoke the descriptor method instead. Where this occurs in the precedence chain depends on which descriptor methods were defined and how they were called.

The starting point for descriptor invocation is a binding, `a.x`. How the arguments are assembled depends on `a`:

#### Direct Call

The simplest and least common call is when user code directly invokes a descriptor method: `x.__get__(a)`.

### Instance Binding

If binding to an object instance, `a.x` is transformed into the call: `type(a).__dict__['x'].__get__(a, type(a)).`

### Class Binding

If binding to a class, `A.x` is transformed into the call: `A.__dict__['x'].__get__(None, A).`

### Super Binding

A dotted lookup such as `super(A, a).x` searches `a.__class__.__mro__` for a base class `B` following `A` and then returns `B.__dict__['x'].__get__(a, A)`. If not a descriptor, `x` is returned unchanged.

For instance bindings, the precedence of descriptor invocation depends on which descriptor methods are defined. A descriptor can define any combination of `__get__()`, `__set__()` and `__delete__()`. If it does not define `__get__()`, then accessing the attribute will return the descriptor object itself unless there is a value in the object's instance dictionary. If the descriptor defines `__set__()` and/or `__delete__()`, it is a data descriptor; if it defines neither, it is a non-data descriptor. Normally, data descriptors define both `__get__()` and `__set__()`, while non-data descriptors have just the `__get__()` method. Data descriptors with `__get__()` and `__set__()` (and/or `__delete__()`) defined always override a redefinition in an instance dictionary. In contrast, non-data descriptors can be overridden by instances.

Python methods (including those decorated with `@staticmethod` and `@classmethod`) are implemented as non-data descriptors. Accordingly, instances can redefine and override methods. This allows individual instances to acquire behaviors that differ from other instances of the same class.

The `property()` function is implemented as a data descriptor. Accordingly, instances cannot override the behavior of a property.

#### 3.3.2.4. `__slots__`

`__slots__` allow us to explicitly declare data members (like properties) and deny the creation of `__dict__` and `__weakref__` (unless explicitly declared in `__slots__` or available in a parent.)

The space saved over using `__dict__` can be significant. Attribute lookup speed can be significantly improved as well.

`object.__slots__`

This class variable can be assigned a string, iterable, or sequence of strings with variable names used by instances.

`__slots__` reserves space for the declared variables and prevents the automatic creation of `__dict__` and `__weakref__` for each instance.

#### 3.3.2.4.1. Notes on using `__slots__`

- When inheriting from a class without `__slots__`, the `__dict__` and `__weakref__` attribute of the instances will always be accessible.
- Without a `__dict__` variable, instances cannot be assigned new variables not listed in the `__slots__` definition. Attempts to assign to an unlisted variable name raises **AttributeError**. If dynamic assignment of new variables is desired, then add `'__dict__'` to the sequence of strings in the `__slots__` declaration.
- Without a `__weakref__` variable for each instance, classes defining `__slots__` do not support **weak references** to its instances. If weak reference support is needed, then add `'__weakref__'` to the sequence of strings in the `__slots__` declaration.
- `__slots__` are implemented at the class level by creating **descriptors** for each variable name. As a result, class attributes cannot be used to set default values for instance variables defined by `__slots__`; otherwise, the class attribute would overwrite the descriptor assignment.
- The action of a `__slots__` declaration is not limited to the class where it is defined. `__slots__` declared in parents are available in child classes. However, child subclasses will get a `__dict__` and `__weakref__` unless they also define `__slots__` (which should only contain names of any *additional* slots).

- If a class defines a slot also defined in a base class, the instance variable defined by the base class slot is inaccessible (except by retrieving its descriptor directly from the base class). This renders the meaning of the program undefined. In the future, a check may be added to prevent this.
- `TypeError` will be raised if nonempty `__slots__` are defined for a class derived from a "variable-length" built-in type such as `int`, `bytes`, and `tuple`.
- Any non-string iterable may be assigned to `__slots__`.
- If a `dictionary` is used to assign `__slots__`, the dictionary keys will be used as the slot names. The values of the dictionary can be used to provide per-attribute docstrings that will be recognised by `inspect.getdoc()` and displayed in the output of `help()`.
- `__class__` assignment works only if both classes have the same `__slots__`.
- Multiple inheritance with multiple slotted parent classes can be used, but only one parent is allowed to have attributes created by slots (the other bases must have empty slot layouts) - violations raise `TypeError`.
- If an `iterator` is used for `__slots__` then a `descriptor` is created for each of the iterator's values. However, the `__slots__` attribute will be an empty iterator.

### 3.3.3. Customizing class creation

Whenever a class inherits from another class, `__init_subclass__()` is called on the parent class. This way, it is possible to write classes which change the behavior of subclasses. This is closely related to class decorators, but where class decorators only affect the specific class they're applied to, `__init_subclass__` solely applies to future subclasses of the class defining the method.

*classmethod* object. `__init_subclass__(cls)`

This method is called whenever the containing class is subclassed. `cls` is then the new subclass. If defined as a normal instance method, this method is implicitly converted to a class method.

Keyword arguments which are given to a new class are passed to the parent's class `__init_subclass__`. For compatibility with other classes using `__init_subclass__`, one should take out the needed keyword arguments and pass the others over to the base class, as in:

```
class Philosopher:
    def __init_subclass__(cls, /, default_name, **kwargs):
        super().__init_subclass__(**kwargs)
        cls.default_name = default_name

class AustralianPhilosopher(Philosopher, default_name="pass"):
```

The default implementation `object.__init_subclass__` does nothing, but raises an error if it is called with any arguments.

### Note

The metaclass hint `metaclass` is consumed by the rest of the type machinery, and is never passed to `__init_subclass__` implementations. The actual metaclass (rather than the explicit hint) can be accessed as `type(cls)`.

*New in version 3.6.*

When a class is created, `type.__new__()` scans the class variables and makes callbacks to those with a `__set_name__()` hook.

`object.__set_name__(self, owner, name)`

Automatically called at the time the owning class *owner* is created. The object has been assigned to *name* in that class:

```
class A:
    x = C() # Automatically calls: x.__set_name__(A, 'x')
```

If the class variable is assigned after the class is created, `__set_name__()` will not be called automatically. If needed, `__set_name__()` can be called directly:

```
class A:
    pass

c = C()
A.x = c                                # The hook is not called
c.__set_name__(A, 'x')                # Manually invoke the hook
```

See [Creating the class object](#) for more details.

*New in version 3.6.*

### 3.3.3.1. Metaclasses

By default, classes are constructed using `type()`. The class body is executed in a new namespace and the class name is bound locally to the result of `type(name, bases, namespace)`.

The class creation process can be customized by passing the `metaclass` keyword argument in the class definition line, or by inheriting from an existing class that included such an argument. In the following example, both `MyClass` and `MySubclass` are instances of `Meta`:

```
class Meta(type):
    pass

class MyClass(metaclass=Meta):
    pass

class MySubclass(MyClass):
    pass
```

Any other keyword arguments that are specified in the class definition are passed through to all metaclass operations described below.

When a class definition is executed, the following steps occur:

- MRO entries are resolved;
- the appropriate metaclass is determined;
- the class namespace is prepared;
- the class body is executed;
- the class object is created.

### 3.3.3.2. Resolving MRO entries

`object.__mro_entries__(self, bases)`

If a base that appears in a class definition is not an instance of `type`, then an `__mro_entries__()` method is searched on the base. If an `__mro_entries__()` method is found, the base is substituted with the result of a call to `__mro_entries__()` when creating the class. The method is called with the original bases tuple passed to the `bases` parameter, and must return a tuple of classes that will be used instead of the base. The returned tuple may be empty: in these cases, the original base is ignored.

See also

`types.resolve_bases()`

Dynamically resolve bases that are not instances of `type`.

**PEP 560** [<https://peps.python.org/pep-0560/>]

Core support for typing module and generic types.

### 3.3.3.3. Determining the appropriate metaclass

The appropriate metaclass for a class definition is determined as follows:

- if no bases and no explicit metaclass are given, then `type()` is used;
- if an explicit metaclass is given and it is *not* an instance of `type()`, then it is used directly as the metaclass;
- if an instance of `type()` is given as the explicit metaclass, or

bases are defined, then the most derived metaclass is used.

The most derived metaclass is selected from the explicitly specified metaclass (if any) and the metaclasses (i.e. `type(cls)`) of all specified base classes. The most derived metaclass is one which is a subtype of *all* of these candidate metaclasses. If none of the candidate metaclasses meets that criterion, then the class definition will fail with `TypeError`.

#### 3.3.3.4. Preparing the class namespace

Once the appropriate metaclass has been identified, then the class namespace is prepared. If the metaclass has a `__prepare__` attribute, it is called as `namespace = metaclass.__prepare__(name, bases, **kwds)` (where the additional keyword arguments, if any, come from the class definition). The `__prepare__` method should be implemented as a **classmethod**. The namespace returned by `__prepare__` is passed in to `__new__`, but when the final class object is created the namespace is copied into a new `dict`.

If the metaclass has no `__prepare__` attribute, then the class namespace is initialised as an empty ordered mapping.

**See also**

**PEP 3115** [<https://peps.python.org/pep-3115/>] - Metaclasses in Python 3000

Introduced the `__prepare__` namespace hook

#### 3.3.3.5. Executing the class body

The class body is executed (approximately) as `exec(body, globals(), namespace)`. The key difference from a normal call to **`exec()`** is that lexical scoping allows the class body (including any methods) to reference names from the current and outer scopes when the class definition occurs inside a function.

However, even when the class definition occurs inside the function,

methods defined inside the class still cannot see names defined at the class scope. Class variables must be accessed through the first parameter of instance or class methods, or through the implicit lexically scoped `__class__` reference described in the next section.

### 3.3.3.6. Creating the class object

Once the class namespace has been populated by executing the class body, the class object is created by calling `metaclass(name, bases, namespace, **kwargs)` (the additional keywords passed here are the same as those passed to `__prepare__`).

This class object is the one that will be referenced by the zero-argument form of `super()`. `__class__` is an implicit closure reference created by the compiler if any methods in a class body refer to either `__class__` or `super`. This allows the zero argument form of `super()` to correctly identify the class being defined based on lexical scoping, while the class or instance that was used to make the current call is identified based on the first argument passed to the method.

**CPython implementation detail:** In CPython 3.6 and later, the `__class__` cell is passed to the metaclass as a `__classcell__` entry in the class namespace. If present, this must be propagated up to the `type.__new__` call in order for the class to be initialised correctly. Failing to do so will result in a `RuntimeError` in Python 3.8.

When using the default metaclass `type`, or any metaclass that ultimately calls `type.__new__`, the following additional customization steps are invoked after creating the class object:

1. The `type.__new__` method collects all of the attributes in the class namespace that define a `__set_name__()` method;
2. Those `__set_name__` methods are called with the class being defined and the assigned name of that particular attribute;
3. The `__init_subclass__()` hook is called on the

immediate parent of the new class in its method resolution order.

After the class object is created, it is passed to the class decorators included in the class definition (if any) and the resulting object is bound in the local namespace as the defined class.

When a new class is created by `type.__new__`, the object provided as the namespace parameter is copied to a new ordered mapping and the original object is discarded. The new copy is wrapped in a read-only proxy, which becomes the `__dict__` attribute of the class object.

### See also

**PEP 3135** [<https://peps.python.org/pep-3135/>] - New super  
Describes the implicit `__class__` closure reference

### 3.3.3.7. Uses for metaclasses

The potential uses for metaclasses are boundless. Some ideas that have been explored include enum, logging, interface checking, automatic delegation, automatic property creation, proxies, frameworks, and automatic resource locking/synchronization.

### 3.3.4. Customizing instance and subclass checks

The following methods are used to override the default behavior of the `isinstance()` and `issubclass()` built-in functions.

In particular, the metaclass `abc.ABCMeta` implements these methods in order to allow the addition of Abstract Base Classes (ABCs) as “virtual base classes” to any class or type (including built-in types), including other ABCs.

`class._instancecheck_(self, instance)`

Return true if *instance* should be considered a (direct or indirect) instance of *class*. If defined, called to implement `isinstance(instance, class)`.

`class.__subclasscheck__(self, subclass)`

Return true if *subclass* should be considered a (direct or indirect) subclass of *class*. If defined, called to implement `issubclass(subclass, class)`.

Note that these methods are looked up on the type (metaclass) of a class. They cannot be defined as class methods in the actual class. This is consistent with the lookup of special methods that are called on instances, only in this case the instance is itself a class.

**See also**

**PEP 3119** [<https://peps.python.org/pep-3119/>] - **Introducing Abstract Base Classes**

Includes the specification for customizing `isinstance()` and `issubclass()` behavior through `__instancecheck__()` and `__subclasscheck__()`, with motivation for this functionality in the context of adding Abstract Base Classes (see the `abc` module) to the language.

### 3.3.5. Emulating generic types

When using [type annotations](#), it is often useful to *parameterize* a [generic type](#) using Python's square-brackets notation. For example, the annotation `list[int]` might be used to signify a [list](#) in which all the elements are of type [int](#).

**See also**

**PEP 484** [<https://peps.python.org/pep-0484/>] - **Type Hints**  
Introducing Python's framework for type annotations

**Generic Alias Types**

Documentation for objects representing parameterized generic classes

**Generics, user-defined generics and `typing.Generic`**

Documentation on how to implement generic classes that

can be parameterized at runtime and understood by static type-checkers.

A class can *generally* only be parameterized if it defines the special class method `__class_getitem__()`.

*classmethod* object.`__class_getitem__(cls, key)`

Return an object representing the specialization of a generic class by type arguments found in *key*.

When defined on a class, `__class_getitem__()` is automatically a class method. As such, there is no need for it to be decorated with `@classmethod` when it is defined.

### 3.3.5.1. The purpose of `__class_getitem__`

The purpose of `__class_getitem__()` is to allow runtime parameterization of standard-library generic classes in order to more easily apply `type hints` to these classes.

To implement custom generic classes that can be parameterized at runtime and understood by static type-checkers, users should either inherit from a standard library class that already implements `__class_getitem__()`, or inherit from `typing.Generic`, which has its own implementation of `__class_getitem__()`.

Custom implementations of `__class_getitem__()` on classes defined outside of the standard library may not be understood by third-party type-checkers such as `mypy`. Using `__class_getitem__()` on any class for purposes other than type hinting is discouraged.

### 3.3.5.2. `__class_getitem__` versus `__getitem__`

Usually, the `subscription` of an object using square brackets will call the `__getitem__()` instance method defined on the object's class. However, if the object being subscribed is itself a class, the class method `__class_getitem__()` may be called instead. `__class_getitem__()` should return a `GenericAlias` object if it is

properly defined.

Presented with the [expression](#) `obj[x]`, the Python interpreter follows something like the following process to decide whether `__getitem__()` or `__class_getitem__()` should be called:

```
from inspect import isclass

def subscribe(obj, x):
    """Return the result of the expression 'obj[x]'''

    class_of_obj = type(obj)

    # If the class of obj defines __getitem__,
    # call class_of_obj.__getitem__(obj, x)
    if hasattr(class_of_obj, '__getitem__'):
        return class_of_obj.__getitem__(obj, x)

    # Else, if obj is a class and defines __class_getitem__
    # call obj.__class_getitem__(x)
    elif isclass(obj) and hasattr(obj, '__class_getitem__'):
        return obj.__class_getitem__(x)

    # Else, raise an exception
    else:
        raise TypeError(
            f"'{class_of_obj.__name__}' object is not subscriptable"
        )
```

In Python, all classes are themselves instances of other classes. The class of a class is known as that class's [metaclass](#), and most classes have the `type` class as their metaclass. `type` does not define `__getitem__()`, meaning that expressions such as `list[int]`, `dict[str, float]` and `tuple[str, bytes]` all result in `__class_getitem__()` being called:

```
>>> # list has class "type" as its metaclass, like most
>>> type(list)
<class 'type'>
>>> type(dict) == type(list) == type(tuple) == type(str)
```

```
True
```

```
>>> # "list[int]" calls "list.__class_getitem__(int)"
>>> list[int]
list[int]
>>> # list.__class_getitem__ returns a GenericAlias object
>>> type(list[int])
<class 'types.GenericAlias'>
```

However, if a class has a custom metaclass that defines `__getitem__()`, subscribing the class may result in different behaviour. An example of this can be found in the `enum` module:

```
>>> from enum import Enum
>>> class Menu(Enum):
...     """A breakfast menu"""
...     SPAM = 'spam'
...     BACON = 'bacon'
...
>>> # Enum classes have a custom metaclass:
>>> type(Menu)
<class 'enum.EnumMeta'>
>>> # EnumMeta defines __getitem__,
>>> # so __class_getitem__ is not called,
>>> # and the result is not a GenericAlias object:
>>> Menu['SPAM']
<Menu.SPAM: 'spam'>
>>> type(Menu['SPAM'])
<enum 'Menu'>
```

### **PEP 560** [<https://peps.python.org/pep-0560/>] - Core Support for typing module and generic types

Introducing `__class_getitem__()`, and outlining when a `subscription` results in `__class_getitem__()` being called instead of `__getitem__()`

## 3.3.6. Emulating callable objects

`object.__call__(self[, args...])`

Called when the instance is “called” as a function; if this method is defined, `x(arg1, arg2, ...)` roughly translates to `type(x).__call__(x, arg1, ...)`.

### 3.3.7. Emulating container types

The following methods can be defined to implement container objects. Containers usually are [sequences](#) (such as [lists](#) or [tuples](#)) or [mappings](#) (like [dictionaries](#)), but can represent other containers as well. The first set of methods is used either to emulate a sequence or to emulate a mapping; the difference is that for a sequence, the allowable keys should be the integers  $k$  for which  $0 \leq k < N$  where  $N$  is the length of the sequence, or [slice](#) objects, which define a range of items. It is also recommended that mappings provide the methods `keys()`, `values()`, `items()`, `get()`, `clear()`, `setdefault()`, `pop()`, `popitem()`, `copy()`, and `update()` behaving similar to those for Python’s standard [dictionary](#) objects. The [collections.abc](#) module provides a [MutableMapping](#) abstract base class to help create those methods from a base set of `__getitem__()`, `__setitem__()`, `__delitem__()`, and `keys()`. Mutable sequences should provide methods `append()`, `count()`, `index()`, `extend()`, `insert()`, `pop()`, `remove()`, `reverse()` and `sort()`, like Python standard [list](#) objects. Finally, sequence types should implement addition (meaning concatenation) and multiplication (meaning repetition) by defining the methods `__add__()`, `__radd__()`, `__iadd__()`, `__mul__()`, `__rmul__()` and `__imul__()` described below; they should not define other numerical operators. It is recommended that both mappings and sequences implement the `__contains__()` method to allow efficient use of the `in` operator; for mappings, `in` should search the mapping’s keys; for sequences, it should search through the values. It is further recommended that both mappings and sequences implement the `__iter__()` method to allow efficient iteration through the container; for mappings, `__iter__()` should iterate through the object’s keys; for sequences, it should iterate through the values.

`object.__len__(self)`

Called to implement the built-in function `len()`. Should return the length of the object, an integer  $\geq 0$ . Also, an object that doesn't define a `__bool__()` method and whose `__len__()` method returns zero is considered to be false in a Boolean context.

**CPython implementation detail:** In CPython, the length is required to be at most `sys.maxsize`. If the length is larger than `sys.maxsize` some features (such as `len()`) may raise `OverflowError`. To prevent raising `OverflowError` by truth value testing, an object must define a `__bool__()` method.

`object.__length_hint__(self)`

Called to implement `operator.length_hint()`. Should return an estimated length for the object (which may be greater or less than the actual length). The length must be an integer  $\geq 0$ . The return value may also be **NotImplemented**, which is treated the same as if the `__length_hint__` method didn't exist at all. This method is purely an optimization and is never required for correctness.

*New in version 3.4.*

## Note

Slicing is done exclusively with the following three methods. A call like

```
a[1:2] = b
```

is translated to

```
a[slice(1, 2, None)] = b
```

and so forth. Missing slice items are always filled in with `None`.

`object.__getitem__(self, key)`

Called to implement evaluation of `self[key]`. For [sequence](#) types, the accepted keys should be integers and slice objects. Note that the special interpretation of negative indexes (if the class wishes to emulate a [sequence](#) type) is up to the `__getitem__()` method. If `key` is of an inappropriate type, `TypeError` may be raised; if of a value outside the set of indexes for the sequence (after any special interpretation of negative values), `IndexError` should be raised. For [mapping](#) types, if `key` is missing (not in the container), `KeyError` should be raised.

### Note

`for` loops expect that an `IndexError` will be raised for illegal indexes to allow proper detection of the end of the sequence.

### Note

When [subscripting](#) a *class*, the special class method `__class_getitem__()` may be called instead of `__getitem__()`. See [\\_\\_class\\_getitem\\_\\_ versus \\_\\_getitem\\_\\_](#) for more details.

`object._setitem__(self, key, value)`

Called to implement assignment to `self[key]`. Same note as for `__getitem__()`. This should only be implemented for mappings if the objects support changes to the values for keys, or if new keys can be added, or for sequences if elements can be replaced. The same exceptions should be raised for improper `key` values as for the `__getitem__()` method.

`object._delitem__(self, key)`

Called to implement deletion of `self[key]`. Same note as for `__getitem__()`. This should only be implemented for mappings if the objects support removal of keys, or for

sequences if elements can be removed from the sequence. The same exceptions should be raised for improper *key* values as for the `__getitem__()` method.

`object._missing_(self, key)`

Called by `dict.__getitem__()` to implement `self[key]` for dict subclasses when *key* is not in the dictionary.

`object._iter_(self)`

This method is called when an *iterator* is required for a container. This method should return a new iterator object that can iterate over all the objects in the container. For mappings, it should iterate over the keys of the container.

`object._reversed_(self)`

Called (if present) by the `reversed()` built-in to implement reverse iteration. It should return a new iterator object that iterates over all the objects in the container in reverse order.

If the `__reversed__()` method is not provided, the `reversed()` built-in will fall back to using the sequence protocol (`__len__()` and `__getitem__()`). Objects that support the sequence protocol should only provide `__reversed__()` if they can provide an implementation that is more efficient than the one provided by `reversed()`.

The membership test operators (`in` and `not in`) are normally implemented as an iteration through a container. However, container objects can supply the following special method with a more efficient implementation, which also does not require the object be iterable.

`object._contains_(self, item)`

Called to implement membership test operators. Should return true if *item* is in *self*, false otherwise. For mapping objects, this should consider the keys of the mapping rather than the values or the key-item pairs.

For objects that don't define `__contains__()`, the membership test first tries iteration via `__iter__()`, then the old sequence iteration protocol via `__getitem__()`, see [this section in the language reference](#).

### 3.3.8. Emulating numeric types

The following methods can be defined to emulate numeric objects. Methods corresponding to operations that are not supported by the particular kind of number implemented (e.g., bitwise operations for non-integral numbers) should be left undefined.

```
object.__add__(self, other)
object.__sub__(self, other)
object.__mul__(self, other)
object.__matmul__(self, other)
object.__truediv__(self, other)
object.__floordiv__(self, other)
object.__mod__(self, other)
object.__divmod__(self, other)
object.__pow__(self, other[, modulo])
object.__lshift__(self, other)
object.__rshift__(self, other)
object.__and__(self, other)
object.__xor__(self, other)
object.__or__(self, other)
```

These methods are called to implement the binary arithmetic operations (+, -, \*, @, /, //, %, `divmod()`, `pow()`, \*\*, <<, >>, &, ^, |). For instance, to evaluate the expression `x + y`, where `x` is an instance of a class that has an `__add__()` method, `type(x).__add__(x, y)` is called. The `__divmod__()` method should be the equivalent to using `__floordiv__()` and `__mod__()`; it should not be related to `__truediv__()`. Note that `__pow__()` should be defined to accept an optional third argument if the ternary version of the built-in `pow()` function is to be supported.

If one of those methods does not support the operation with the supplied arguments, it should return `NotImplemented`.

```
object._radd_(self, other)
object._rsub_(self, other)
object._rmul_(self, other)
object._rmatmul_(self, other)
object._rtruediv_(self, other)
object._rfloordiv_(self, other)
object._rmod_(self, other)
object._rdivmod_(self, other)
object._rpow_(self, other[, modulo])
object._rlshift_(self, other)
object._rrshift_(self, other)
object._rand_(self, other)
object._rxor_(self, other)
object._ror_(self, other)
```

These methods are called to implement the binary arithmetic operations (+, −, \*, @, /, //, %, `divmod()`, `pow()`, \*\*, <<, >>, &, ^, |) with reflected (swapped) operands. These functions are only called if the left operand does not support the corresponding operation 3 and the operands are of different types. 4 For instance, to evaluate the expression `x − y`, where `y` is an instance of a class that has an `__rsub__()` method, `type(y).__rsub__(y, x)` is called if `type(x).__sub__(x, y)` returns *NotImplemented*.

Note that ternary `pow()` will not try calling `__rpow__()` (the coercion rules would become too complicated).

## Note

If the right operand's type is a subclass of the left operand's type and that subclass provides a different implementation of the reflected method for the operation, this method will be called before the left operand's non-reflected method. This behavior allows subclasses to

override their ancestors' operations.

```
object.__iadd__(self, other)
object.__isub__(self, other)
object.__imul__(self, other)
object.__imatmul__(self, other)
object.__itruediv__(self, other)
object.__ifloordiv__(self, other)
object.__imod__(self, other)
object.__ipow__(self, other[, modulo])
object.__lshift__(self, other)
object.__rshift__(self, other)
object.__iand__(self, other)
object.__ixor__(self, other)
object.__ior__(self, other)
```

These methods are called to implement the augmented arithmetic assignments ( $+=$ ,  $-=$ ,  $*=$ ,  $@=$ ,  $/=$ ,  $//=$ ,  $\%=$ ,  $**=$ ,  $<<=$ ,  $>>=$ ,  $\&=$ ,  $\^=$ ,  $|=$ ). These methods should attempt to do the operation in-place (modifying *self*) and return the result (which could be, but does not have to be, *self*). If a specific method is not defined, the augmented assignment falls back to the normal methods. For instance, if *x* is an instance of a class with an `__iadd__()` method,  $x += y$  is equivalent to  $x = x.__iadd__(y)$ . Otherwise,  $x.__add__(y)$  and  $y.__radd__(x)$  are considered, as with the evaluation of  $x + y$ . In certain situations, augmented assignment can result in unexpected errors (see [Why does a `tuple\[i\] += \['item'\]` raise an exception when the addition works?](#)), but this behavior is in fact part of the data model.

```
object.__neg__(self)
object.__pos__(self)
object.__abs__(self)
object.__invert__(self)
```

Called to implement the unary arithmetic operations ( $-$ ,  $+$ , `abs()` and `~`).

`object._complex_(self)`

`object._int_(self)`

`object._float_(self)`

Called to implement the built-in functions `complex()`, `int()` and `float()`. Should return a value of the appropriate type.

`object._index_(self)`

Called to implement `operator.index()`, and whenever Python needs to losslessly convert the numeric object to an integer object (such as in slicing, or in the built-in `bin()`, `hex()` and `oct()` functions). Presence of this method indicates that the numeric object is an integer type. Must return an integer.

If `__int__()`, `__float__()` and `__complex__()` are not defined then corresponding built-in functions `int()`, `float()` and `complex()` fall back to `__index__()`.

`object._round_(self[, ndigits])`

`object._trunc_(self)`

`object._floor_(self)`

`object._ceil_(self)`

Called to implement the built-in function `round()` and `math` functions `trunc()`, `floor()` and `ceil()`. Unless `ndigits` is passed to `__round__()` all these methods should return the value of the object truncated to an `Integral` (typically an `int`).

The built-in function `int()` falls back to `__trunc__()` if neither `__int__()` nor `__index__()` is defined.

*Changed in version 3.11:* The delegation of `int()` to `__trunc__()` is deprecated.

### 3.3.9. With Statement Context Managers

A *context manager* is an object that defines the runtime context to be established when executing a **with** statement. The context manager handles the entry into, and the exit from, the desired runtime context for the execution of the block of code. Context managers are normally invoked using the **with** statement (described in section [The with statement](#)), but can also be used by directly invoking their methods.

Typical uses of context managers include saving and restoring various kinds of global state, locking and unlocking resources, closing opened files, etc.

For more information on context managers, see [Context Manager Types](#).

`object._enter_(self)`

Enter the runtime context related to this object. The **with** statement will bind this method's return value to the target(s) specified in the **as** clause of the statement, if any.

`object._exit_(self, exc_type, exc_value, traceback)`

Exit the runtime context related to this object. The parameters describe the exception that caused the context to be exited. If the context was exited without an exception, all three arguments will be **None**.

If an exception is supplied, and the method wishes to suppress the exception (i.e., prevent it from being propagated), it should return a true value. Otherwise, the exception will be processed normally upon exit from this method.

Note that `__exit__()` methods should not reraise the passed-in exception; this is the caller's responsibility.

**See also**

### PEP 343 [<https://peps.python.org/pep-0343/>] - The “with” statement

The specification, background, and examples for the Python `with` statement.

### 3.3.10. Customizing positional arguments in class pattern matching

When using a class name in a pattern, positional arguments in the pattern are not allowed by default, i.e. `case MyClass(x, y)` is typically invalid without special support in `MyClass`. To be able to use that kind of pattern, the class needs to define a `__match_args__` attribute.

object.`__match_args__`

This class variable can be assigned a tuple of strings. When this class is used in a class pattern with positional arguments, each positional argument will be converted into a keyword argument, using the corresponding value in `__match_args__` as the keyword. The absence of this attribute is equivalent to setting it to `()`.

For example, if `MyClass.__match_args__` is `("left", "center", "right")` that means that `case MyClass(x, y)` is equivalent to `case MyClass(left=x, center=y)`. Note that the number of arguments in the pattern must be smaller than or equal to the number of elements in `__match_args__`; if it is larger, the pattern match attempt will raise a `TypeError`.

*New in version 3.10.*

See also

### PEP 634 [<https://peps.python.org/pep-0634/>] - Structural Pattern Matching

The specification for the Python `match` statement.

### 3.3.11. Special method lookup

For custom classes, implicit invocations of special methods are only guaranteed to work correctly if defined on an object's type, not in the object's instance dictionary. That behaviour is the reason why the following code raises an exception:

```
>>> class C:
...     pass
...
>>> c = C()
>>> c.__len__ = lambda: 5
>>> len(c)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object of type 'C' has no len()
```

The rationale behind this behaviour lies with a number of special methods such as `__hash__()` and `__repr__()` that are implemented by all objects, including type objects. If the implicit lookup of these methods used the conventional lookup process, they would fail when invoked on the type object itself:

```
>>> 1.__hash__() == hash(1)
True
>>> int.__hash__() == hash(int)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: descriptor '__hash__' of 'int' object needs a
```

Incorrectly attempting to invoke an unbound method of a class in this way is sometimes referred to as 'metaclass confusion', and is avoided by bypassing the instance when looking up special methods:

```
>>> type(1).__hash__(1) == hash(1)
True
>>> type(int).__hash__(int) == hash(int)
True
```

In addition to bypassing any instance attributes in the interest of correctness, implicit special method lookup generally also bypasses

the `__getattrattribute__()` method even of the object's metaclass:

```
>>> class Meta(type):
...     def __getattrattribute__(*args):
...         print("Metaclass getattrattribute invoked")
...         return type.__getattrattribute__(*args)
...
>>> class C(object, metaclass=Meta):
...     def __len__(self):
...         return 10
...     def __getattrattribute__(*args):
...         print("Class getattrattribute invoked")
...         return object.__getattrattribute__(*args)
...
>>> c = C()
>>> c.__len__()                                # Explicit lookup via in
Class getattrattribute invoked
10
>>> type(c).__len__(c)                          # Explicit lookup via ty
Metaclass getattrattribute invoked
10
>>> len(c)                                     # Implicit lookup
10
```

Bypassing the `__getattrattribute__()` machinery in this fashion provides significant scope for speed optimisations within the interpreter, at the cost of some flexibility in the handling of special methods (the special method *must* be set on the class object itself in order to be consistently invoked by the interpreter).

## 3.4. Coroutines

### 3.4.1. Awaitable Objects

An [awaitable](#) object generally implements an `__await__()` method. [Coroutine objects](#) returned from `async def` functions are awaitable.

## Note

The `generator iterator` objects returned from generators decorated with `types.coroutine()` are also awaitable, but they do not implement `__await__()`.

`object.__await__(self)`

Must return an `iterator`. Should be used to implement `awaitable` objects. For instance, `asyncio.Future` implements this method to be compatible with the `await` expression.

## Note

The language doesn't place any restriction on the type or value of the objects yielded by the iterator returned by `__await__`, as this is specific to the implementation of the asynchronous execution framework (e.g. `asyncio`) that will be managing the `awaitable` object.

*New in version 3.5.*

## See also

**PEP 492** [<https://peps.python.org/pep-0492/>] for additional information about awaitable objects.

## 3.4.2. Coroutine Objects

`Coroutine objects` are `awaitable` objects. A coroutine's execution can be controlled by calling `__await__()` and iterating over the result. When the coroutine has finished executing and returns, the iterator raises `StopIteration`, and the exception's `value` attribute holds the return value. If the coroutine raises an exception, it is propagated by the iterator. Coroutines should not directly raise unhandled `StopIteration` exceptions.

Coroutines also have the methods listed below, which are analogous to those of generators (see [Generator-iterator methods](#)). However, unlike generators, coroutines do not directly support iteration.

*Changed in version 3.5.2:* It is a `RuntimeError` to await on a coroutine more than once.

`coroutine.send(value)`

Starts or resumes execution of the coroutine. If `value` is `None`, this is equivalent to advancing the iterator returned by `__await__()`. If `value` is not `None`, this method delegates to the `send()` method of the iterator that caused the coroutine to suspend. The result (return value, `StopIteration`, or other exception) is the same as when iterating over the `__await__()` return value, described above.

`coroutine.throw(value)`

`coroutine.throw(type[, value[, traceback]])`

Raises the specified exception in the coroutine. This method delegates to the `throw()` method of the iterator that caused the coroutine to suspend, if it has such a method. Otherwise, the exception is raised at the suspension point. The result (return value, `StopIteration`, or other exception) is the same as when iterating over the `__await__()` return value, described above. If the exception is not caught in the coroutine, it propagates back to the caller.

`coroutine.close()`

Causes the coroutine to clean itself up and exit. If the coroutine is suspended, this method first delegates to the `close()` method of the iterator that caused the coroutine to suspend, if it has such a method. Then it raises `GeneratorExit` at the suspension point, causing the coroutine to immediately clean itself up. Finally, the coroutine is marked as having finished executing, even if it was never started.

Coroutine objects are automatically closed using the above process when they are about to be destroyed.

### 3.4.3. Asynchronous Iterators

An *asynchronous iterator* can call asynchronous code in its `__anext__` method.

Asynchronous iterators can be used in an `async for` statement.

`object.__aiter__(self)`

Must return an *asynchronous iterator* object.

`object.__anext__(self)`

Must return an *awaitable* resulting in a next value of the iterator. Should raise a `StopAsyncIteration` error when the iteration is over.

An example of an asynchronous iterable object:

```
class Reader:
    async def readline(self):
        ...

    def __aiter__(self):
        return self

    async def __anext__(self):
        val = await self.readline()
        if val == b'':
            raise StopAsyncIteration
        return val
```

*New in version 3.5.*

*Changed in version 3.7:* Prior to Python 3.7, `__aiter__()` could return an *awaitable* that would resolve to an *asynchronous iterator*.

Starting with Python 3.7, `__aiter__()` must return an asynchronous iterator object. Returning anything else will result in a `TypeError` error.

### 3.4.4. Asynchronous Context Managers

An *asynchronous context manager* is a *context manager* that is able to suspend execution in its `__aenter__` and `__aexit__` methods.

Asynchronous context managers can be used in an `async with` statement.

`object.__aenter__(self)`

Semantically similar to `__enter__()`, the only difference being that it must return an *awaitable*.

`object.__aexit__(self, exc_type, exc_value, traceback)`

Semantically similar to `__exit__()`, the only difference being that it must return an *awaitable*.

An example of an asynchronous context manager class:

```
class AsyncContextManager:
    async def __aenter__(self):
        await log('entering context')

    async def __aexit__(self, exc_type, exc, tb):
        await log('exiting context')
```

*New in version 3.5.*

## Footnotes

1

It is possible in some cases to change an object's type, under certain controlled conditions. It generally isn't a good idea though, since it can lead to some very strange behaviour if it is handled incorrectly.

2

The `__hash__()`, `__iter__()`, `__reversed__()`, and `__contains__()` methods have special handling for this;

others will still raise a `TypeError`, but may do so by relying on the behavior that `None` is not callable.

3

“Does not support” here means that the class has no such method, or the method returns `NotImplemented`. Do not set the method to `None` if you want to force fallback to the right operand’s reflected method—that will instead have the opposite effect of explicitly *blocking* such fallback.

4

For operands of the same type, it is assumed that if the non-reflected method – such as `__add__()` – fails then the overall operation is not supported, which is why the reflected method is not called.

# 4. Execution model

## 4.1. Structure of a program

A Python program is constructed from code blocks. A *block* is a piece of Python program text that is executed as a unit. The following are blocks: a module, a function body, and a class definition. Each command typed interactively is a block. A script file (a file given as standard input to the interpreter or specified as a command line argument to the interpreter) is a code block. A script command (a command specified on the interpreter command line with the `-c` option) is a code block. A module run as a top level script (as module `__main__`) from the command line using a `-m` argument is also a code block. The string argument passed to the built-in functions `eval()` and `exec()` is a code block.

A code block is executed in an *execution frame*. A frame contains some administrative information (used for debugging) and determines where and how execution continues after the code block's execution has completed.

## 4.2. Naming and binding

### 4.2.1. Binding of names

*Names* refer to objects. Names are introduced by name binding operations.

The following constructs bind names:

- formal parameters to functions,
- class definitions,
- function definitions,
- assignment expressions,
- `targets` that are identifiers if occurring in an assignment:

- `for` loop header,
- after `as` in a `with` statement, `except` clause, `except*` clause, or in the `as`-pattern in structural pattern matching,
- in a capture pattern in structural pattern matching
- `import` statements.

The `import` statement of the form `from ... import *` binds all names defined in the imported module, except those beginning with an underscore. This form may only be used at the module level.

A target occurring in a `del` statement is also considered bound for this purpose (though the actual semantics are to unbind the name).

Each assignment or import statement occurs within a block defined by a class or function definition or at the module level (the top-level code block).

If a name is bound in a block, it is a local variable of that block, unless declared as `nonlocal` or `global`. If a name is bound at the module level, it is a global variable. (The variables of the module code block are local and global.) If a variable is used in a code block but not defined there, it is a *free variable*.

Each occurrence of a name in the program text refers to the *binding* of that name established by the following name resolution rules.

### 4.2.2. Resolution of names

A *scope* defines the visibility of a name within a block. If a local variable is defined in a block, its scope includes that block. If the definition occurs in a function block, the scope extends to any blocks contained within the defining one, unless a contained block introduces a different binding for the name.

When a name is used in a code block, it is resolved using the nearest enclosing scope. The set of all such scopes visible to a code block is called the block's *environment*.

When a name is not found at all, a `NameError` exception is raised.

If the current scope is a function scope, and the name refers to a local variable that has not yet been bound to a value at the point where the name is used, an `UnboundLocalError` exception is raised. `UnboundLocalError` is a subclass of `NameError`.

If a name binding operation occurs anywhere within a code block, all uses of the name within the block are treated as references to the current block. This can lead to errors when a name is used within a block before it is bound. This rule is subtle. Python lacks declarations and allows name binding operations to occur anywhere within a code block. The local variables of a code block can be determined by scanning the entire text of the block for name binding operations. See [the FAQ entry on UnboundLocalError](#) for examples.

If the `global` statement occurs within a block, all uses of the names specified in the statement refer to the bindings of those names in the top-level namespace. Names are resolved in the top-level namespace by searching the global namespace, i.e. the namespace of the module containing the code block, and the builtins namespace, the namespace of the module `builtins`. The global namespace is searched first. If the names are not found there, the builtins namespace is searched. The `global` statement must precede all uses of the listed names.

The `global` statement has the same scope as a name binding operation in the same block. If the nearest enclosing scope for a free variable contains a global statement, the free variable is treated as a global.

The `nonlocal` statement causes corresponding names to refer to previously bound variables in the nearest enclosing function scope. `SyntaxError` is raised at compile time if the given name does not exist in any enclosing function scope.

The namespace for a module is automatically created the first time a module is imported. The main module for a script is always called `__main__`.

Class definition blocks and arguments to `exec()` and `eval()` are special in the context of name resolution. A class definition is an

executable statement that may use and define names. These references follow the normal rules for name resolution with an exception that unbound local variables are looked up in the global namespace. The namespace of the class definition becomes the attribute dictionary of the class. The scope of names defined in a class block is limited to the class block; it does not extend to the code blocks of methods – this includes comprehensions and generator expressions since they are implemented using a function scope. This means that the following will fail:

```
class A:
    a = 42
    b = list(a + i for i in range(10))
```

### 4.2.3. Builtins and restricted execution

**CPython implementation detail:** Users should not touch `__builtins__`; it is strictly an implementation detail. Users wanting to override values in the builtins namespace should `import` the `builtins` module and modify its attributes appropriately.

The builtins namespace associated with the execution of a code block is actually found by looking up the name `__builtins__` in its global namespace; this should be a dictionary or a module (in the latter case the module's dictionary is used). By default, when in the `__main__` module, `__builtins__` is the built-in module `builtins`; when in any other module, `__builtins__` is an alias for the dictionary of the `builtins` module itself.

### 4.2.4. Interaction with dynamic features

Name resolution of free variables occurs at runtime, not at compile time. This means that the following code will print 42:

```
i = 10
def f():
    print(i)
i = 42
f()
```

The `eval()` and `exec()` functions do not have access to the full environment for resolving names. Names may be resolved in the local and global namespaces of the caller. Free variables are not resolved in the nearest enclosing namespace, but in the global namespace. <sup>1</sup> The `exec()` and `eval()` functions have optional arguments to override the global and local namespace. If only one namespace is specified, it is used for both.

## 4.3. Exceptions

Exceptions are a means of breaking out of the normal flow of control of a code block in order to handle errors or other exceptional conditions. An exception is *raised* at the point where the error is detected; it may be *handled* by the surrounding code block or by any code block that directly or indirectly invoked the code block where the error occurred.

The Python interpreter raises an exception when it detects a run-time error (such as division by zero). A Python program can also explicitly raise an exception with the `raise` statement. Exception handlers are specified with the `try ... except` statement. The `finally` clause of such a statement can be used to specify cleanup code which does not handle the exception, but is executed whether an exception occurred or not in the preceding code.

Python uses the “termination” model of error handling: an exception handler can find out what happened and continue execution at an outer level, but it cannot repair the cause of the error and retry the failing operation (except by re-entering the offending piece of code from the top).

When an exception is not handled at all, the interpreter terminates execution of the program, or returns to its interactive main loop. In either case, it prints a stack traceback, except when the exception is `SystemExit`.

Exceptions are identified by class instances. The `except` clause is selected depending on the class of the instance: it must reference the class of the instance or a `non-virtual base class` thereof. The instance can be received by the handler and can carry additional

information about the exceptional condition.

### Note

Exception messages are not part of the Python API. Their contents may change from one version of Python to the next without warning and should not be relied on by code which will run under multiple versions of the interpreter.

See also the description of the `try` statement in section [The try statement](#) and `raise` statement in section [The raise statement](#).

### Footnotes

1

This limitation occurs because the code that is executed by these operations is not available at the time the module is compiled.

## 5. The import system

Python code in one `module` gains access to the code in another module by the process of `importing` it. The `import` statement is the most common way of invoking the import machinery, but it is not the only way. Functions such as `importlib.import_module()` and built-in `__import__()` can also be used to invoke the import machinery.

The `import` statement combines two operations; it searches for the named module, then it binds the results of that search to a name in the local scope. The search operation of the `import` statement is defined as a call to the `__import__()` function, with the appropriate arguments. The return value of `__import__()` is used to perform the name binding operation of the `import` statement. See the `import` statement for the exact details of that name binding operation.

A direct call to `__import__()` performs only the module search and, if found, the module creation operation. While certain side-effects may occur, such as the importing of parent packages, and the updating of various caches (including `sys.modules`), only the `import` statement performs a name binding operation.

When an `import` statement is executed, the standard builtin `__import__()` function is called. Other mechanisms for invoking the import system (such as `importlib.import_module()`) may choose to bypass `__import__()` and use their own solutions to implement import semantics.

When a module is first imported, Python searches for the module and if found, it creates a module object `1`, initializing it. If the named module cannot be found, a `ModuleNotFoundError` is raised. Python implements various strategies to search for the named module when the import machinery is invoked. These strategies can be modified and extended by using various hooks described in the sections below.

*Changed in version 3.3:* The import system has been updated to fully implement the second phase of [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/]. There is no longer any implicit import machinery - the full import system is exposed through `sys.meta_path`. In addition, native namespace package support has been implemented (see [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/]).

## 5.1. `importlib`

The `importlib` module provides a rich API for interacting with the import system. For example `importlib.import_module()` provides a recommended, simpler API than built-in `__import__()` for invoking the import machinery. Refer to the `importlib` library documentation for additional detail.

## 5.2. Packages

Python has only one type of module object, and all modules are of this type, regardless of whether the module is implemented in Python, C, or something else. To help organize modules and provide a naming hierarchy, Python has a concept of [packages](#).

You can think of packages as the directories on a file system and modules as files within directories, but don't take this analogy too literally since packages and modules need not originate from the file system. For the purposes of this documentation, we'll use this convenient analogy of directories and files. Like file system directories, packages are organized hierarchically, and packages may themselves contain subpackages, as well as regular modules.

It's important to keep in mind that all packages are modules, but not all modules are packages. Or put another way, packages are just a special kind of module. Specifically, any module that contains a `__path__` attribute is considered a package.

All modules have a name. Subpackage names are separated from their parent package name by a dot, akin to Python's standard attribute access syntax. Thus you might have a package called `email`, which in turn has a subpackage called `email.mime` and a

module within that subpackage called `email.mime.text`.

### 5.2.1. Regular packages

Python defines two types of packages, [regular packages](#) and [namespace packages](#). Regular packages are traditional packages as they existed in Python 3.2 and earlier. A regular package is typically implemented as a directory containing an `__init__.py` file. When a regular package is imported, this `__init__.py` file is implicitly executed, and the objects it defines are bound to names in the package's namespace. The `__init__.py` file can contain the same Python code that any other module can contain, and Python will add some additional attributes to the module when it is imported.

For example, the following file system layout defines a top level parent package with three subpackages:

```
parent/  
    __init__.py  
    one/  
        __init__.py  
    two/  
        __init__.py  
    three/  
        __init__.py
```

Importing `parent.one` will implicitly execute `parent/__init__.py` and `parent/one/__init__.py`. Subsequent imports of `parent.two` or `parent.three` will execute `parent/two/__init__.py` and `parent/three/__init__.py` respectively.

### 5.2.2. Namespace packages

A namespace package is a composite of various [portions](#), where each portion contributes a subpackage to the parent package. Portions may reside in different locations on the file system. Portions may also be found in zip files, on the network, or anywhere else that Python searches during import. Namespace

packages may or may not correspond directly to objects on the file system; they may be virtual modules that have no concrete representation.

Namespace packages do not use an ordinary list for their `__path__` attribute. They instead use a custom iterable type which will automatically perform a new search for package portions on the next import attempt within that package if the path of their parent package (or `sys.path` for a top level package) changes.

With namespace packages, there is no `parent/__init__.py` file. In fact, there may be multiple `parent` directories found during import search, where each one is provided by a different portion. Thus `parent/one` may not be physically located next to `parent/two`. In this case, Python will create a namespace package for the top-level `parent` package whenever it or one of its subpackages is imported.

See also [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/] for the namespace package specification.

## 5.3. Searching

To begin the search, Python needs the **fully qualified** name of the module (or package, but for the purposes of this discussion, the difference is immaterial) being imported. This name may come from various arguments to the `import` statement, or from the parameters to the `importlib.import_module()` or `__import__()` functions.

This name will be used in various phases of the import search, and it may be the dotted path to a submodule, e.g. `foo.bar.baz`. In this case, Python first tries to import `foo`, then `foo.bar`, and finally `foo.bar.baz`. If any of the intermediate imports fail, a `ModuleNotFoundError` is raised.

### 5.3.1. The module cache

The first place checked during import search is `sys.modules`. This mapping serves as a cache of all modules that have been

previously imported, including the intermediate paths. So if `foo.bar.baz` was previously imported, `sys.modules` will contain entries for `foo`, `foo.bar`, and `foo.bar.baz`. Each key will have as its value the corresponding module object.

During import, the module name is looked up in `sys.modules` and if present, the associated value is the module satisfying the import, and the process completes. However, if the value is `None`, then a `ModuleNotFoundError` is raised. If the module name is missing, Python will continue searching for the module.

`sys.modules` is writable. Deleting a key may not destroy the associated module (as other modules may hold references to it), but it will invalidate the cache entry for the named module, causing Python to search anew for the named module upon its next import. The key can also be assigned to `None`, forcing the next import of the module to result in a `ModuleNotFoundError`.

Beware though, as if you keep a reference to the module object, invalidate its cache entry in `sys.modules`, and then re-import the named module, the two module objects will *not* be the same. By contrast, `importlib.reload()` will reuse the *same* module object, and simply reinitialise the module contents by rerunning the module's code.

### 5.3.2. Finders and loaders

If the named module is not found in `sys.modules`, then Python's import protocol is invoked to find and load the module. This protocol consists of two conceptual objects, `finders` and `loaders`. A finder's job is to determine whether it can find the named module using whatever strategy it knows about. Objects that implement both of these interfaces are referred to as `importers` - they return themselves when they find that they can load the requested module.

Python includes a number of default finders and importers. The first one knows how to locate built-in modules, and the second knows how to locate frozen modules. A third default finder searches an `import path` for modules. The `import path` is a list of locations that may name file system paths or zip files. It can also be extended to search for any locatable resource, such as those identified by URLs.

The import machinery is extensible, so new finders can be added to extend the range and scope of module searching.

Finders do not actually load modules. If they can find the named module, they return a *module spec*, an encapsulation of the module's import-related information, which the import machinery then uses when loading the module.

The following sections describe the protocol for finders and loaders in more detail, including how you can create and register new ones to extend the import machinery.

*Changed in version 3.4:* In previous versions of Python, finders returned [loaders](#) directly, whereas now they return module specs which *contain* loaders. Loaders are still used during import but have fewer responsibilities.

### 5.3.3. Import hooks

The import machinery is designed to be extensible; the primary mechanism for this are the *import hooks*. There are two types of import hooks: *meta hooks* and *import path hooks*.

Meta hooks are called at the start of import processing, before any other import processing has occurred, other than [sys.modules](#) cache look up. This allows meta hooks to override [sys.path](#) processing, frozen modules, or even built-in modules. Meta hooks are registered by adding new finder objects to [sys.meta\\_path](#), as described below.

Import path hooks are called as part of [sys.path](#) (or `package.__path__`) processing, at the point where their associated path item is encountered. Import path hooks are registered by adding new callables to [sys.path\\_hooks](#) as described below.

### 5.3.4. The meta path

When the named module is not found in [sys.modules](#), Python next searches [sys.meta\\_path](#), which contains a list of meta path finder objects. These finders are queried in order to see if they know

how to handle the named module. Meta path finders must implement a method called `find_spec()` which takes three arguments: a name, an import path, and (optionally) a target module. The meta path finder can use any strategy it wants to determine whether it can handle the named module or not.

If the meta path finder knows how to handle the named module, it returns a spec object. If it cannot handle the named module, it returns `None`. If `sys.meta_path` processing reaches the end of its list without returning a spec, then a `ModuleNotFoundError` is raised. Any other exceptions raised are simply propagated up, aborting the import process.

The `find_spec()` method of meta path finders is called with two or three arguments. The first is the fully qualified name of the module being imported, for example `foo.bar.baz`. The second argument is the path entries to use for the module search. For top-level modules, the second argument is `None`, but for submodules or subpackages, the second argument is the value of the parent package's `__path__` attribute. If the appropriate `__path__` attribute cannot be accessed, a `ModuleNotFoundError` is raised. The third argument is an existing module object that will be the target of loading later. The import system passes in a target module only during reload.

The meta path may be traversed multiple times for a single import request. For example, assuming none of the modules involved has already been cached, importing `foo.bar.baz` will first perform a top level import, calling `mpf.find_spec("foo", None, None)` on each meta path finder (`mpf`). After `foo` has been imported, `foo.bar` will be imported by traversing the meta path a second time, calling `mpf.find_spec("foo.bar", foo.__path__, None)`. Once `foo.bar` has been imported, the final traversal will call `mpf.find_spec("foo.bar.baz", foo.bar.__path__, None)`.

Some meta path finders only support top level imports. These importers will always return `None` when anything other than `None` is passed as the second argument.

Python's default `sys.meta_path` has three meta path finders, one

that knows how to import built-in modules, one that knows how to import frozen modules, and one that knows how to import modules from an [import path](#) (i.e. the [path based finder](#)).

*Changed in version 3.4:* The `find_spec()` method of meta path finders replaced `find_module()`, which is now deprecated. While it will continue to work without change, the import machinery will try it only if the finder does not implement `find_spec()`.

*Changed in version 3.10:* Use of `find_module()` by the import system now raises `ImportWarning`.

## 5.4. Loading

If and when a module spec is found, the import machinery will use it (and the loader it contains) when loading the module. Here is an approximation of what happens during the loading portion of import:

```
module = None
if spec.loader is not None and hasattr(spec.loader, 'create_module'):
    # It is assumed 'exec_module' will also be defined on the loader
    module = spec.loader.create_module(spec)
if module is None:
    module = ModuleType(spec.name)
# The import-related module attributes get set here:
_init_module_attrs(spec, module)

if spec.loader is None:
    # unsupported
    raise ImportError

if spec.origin is None and spec.submodule_search_locations:
    # namespace package
    sys.modules[spec.name] = module
elif not hasattr(spec.loader, 'exec_module'):
    module = spec.loader.load_module(spec.name)
    # Set __loader__ and __package__ if missing.
else:
    sys.modules[spec.name] = module
```

```

try:
    spec.loader.exec_module(module)
except BaseException:
    try:
        del sys.modules[spec.name]
    except KeyError:
        pass
    raise
return sys.modules[spec.name]

```

Note the following details:

- If there is an existing module object with the given name in `sys.modules`, import will have already returned it.
- The module will exist in `sys.modules` before the loader executes the module code. This is crucial because the module code may (directly or indirectly) import itself; adding it to `sys.modules` beforehand prevents unbounded recursion in the worst case and multiple loading in the best.
- If loading fails, the failing module – and only the failing module – gets removed from `sys.modules`. Any module already in the `sys.modules` cache, and any module that was successfully loaded as a side-effect, must remain in the cache. This contrasts with reloading where even the failing module is left in `sys.modules`.
- After the module is created but before execution, the import machinery sets the import-related module attributes (“`_init_module_attrs`” in the pseudo-code example above), as summarized in a [later section](#).
- Module execution is the key moment of loading in which the module’s namespace gets populated. Execution is entirely delegated to the loader, which gets to decide

what gets populated and how.

- The module created during loading and passed to `exec_module()` may not be the one returned at the end of `import` 2.

*Changed in version 3.4:* The import system has taken over the boilerplate responsibilities of loaders. These were previously performed by the `importlib.abc.Loader.load_module()` method.

### 5.4.1. Loaders

Module loaders provide the critical function of loading: module execution. The import machinery calls the `importlib.abc.Loader.exec_module()` method with a single argument, the module object to execute. Any value returned from `exec_module()` is ignored.

Loaders must satisfy the following requirements:

- If the module is a Python module (as opposed to a built-in module or a dynamically loaded extension), the loader should execute the module's code in the module's global name space (`module.__dict__`).
- If the loader cannot execute the module, it should raise an `ImportError`, although any other exception raised during `exec_module()` will be propagated.

In many cases, the finder and loader can be the same object; in such cases the `find_spec()` method would just return a spec with the loader set to `self`.

Module loaders may opt in to creating the module object during loading by implementing a `create_module()` method. It takes one argument, the module spec, and returns the new module object to use during loading. `create_module()` does not need to set any attributes on the module object. If the method returns `None`, the import machinery will create the new module itself.

*New in version 3.4:* The `create_module()` method of loaders.

*Changed in version 3.4:* The `load_module()` method was replaced by `exec_module()` and the import machinery assumed all the boilerplate responsibilities of loading.

For compatibility with existing loaders, the import machinery will use the `load_module()` method of loaders if it exists and the loader does not also implement `exec_module()`. However, `load_module()` has been deprecated and loaders should implement `exec_module()` instead.

The `load_module()` method must implement all the boilerplate loading functionality described above in addition to executing the module. All the same constraints apply, with some additional clarification:

- If there is an existing module object with the given name in `sys.modules`, the loader must use that existing module. (Otherwise, `importlib.reload()` will not work correctly.) If the named module does not exist in `sys.modules`, the loader must create a new module object and add it to `sys.modules`.
- The module *must* exist in `sys.modules` before the loader executes the module code, to prevent unbounded recursion or multiple loading.
- If loading fails, the loader must remove any modules it has inserted into `sys.modules`, but it must remove **only** the failing module(s), and only if the loader itself has loaded the module(s) explicitly.

*Changed in version 3.5:* A `DeprecationWarning` is raised when `exec_module()` is defined but `create_module()` is not.

*Changed in version 3.6:* An `ImportError` is raised when `exec_module()` is defined but `create_module()` is not.

*Changed in version 3.10:* Use of `load_module()` will raise **ImportWarning**.

## 5.4.2. Submodules

When a submodule is loaded using any mechanism (e.g. `importlib` APIs, the `import` or `import-from` statements, or built-in `__import__()`) a binding is placed in the parent module's namespace to the submodule object. For example, if package `spam` has a submodule `foo`, after importing `spam.foo`, `spam` will have an attribute `foo` which is bound to the submodule. Let's say you have the following directory structure:

```
spam/  
    __init__.py  
    foo.py
```

and `spam/__init__.py` has the following line in it:

```
from .foo import Foo
```

then executing the following puts name bindings for `foo` and `Foo` in the `spam` module:

```
>>> import spam  
>>> spam.foo  
<module 'spam.foo' from '/tmp/imports/spam/foo.py'>  
>>> spam.Foo  
<class 'spam.foo.Foo'>
```

Given Python's familiar name binding rules this might seem surprising, but it's actually a fundamental feature of the import system. The invariant holding is that if you have `sys.modules['spam']` and `sys.modules['spam.foo']` (as you would after the above import), the latter must appear as the `foo` attribute of the former.

## 5.4.3. Module spec

The import machinery uses a variety of information about each

module during import, especially before loading. Most of the information is common to all modules. The purpose of a module's spec is to encapsulate this import-related information on a per-module basis.

Using a spec during import allows state to be transferred between import system components, e.g. between the finder that creates the module spec and the loader that executes it. Most importantly, it allows the import machinery to perform the boilerplate operations of loading, whereas without a module spec the loader had that responsibility.

The module's spec is exposed as the `__spec__` attribute on a module object. See [ModuleSpec](#) for details on the contents of the module spec.

*New in version 3.4.*

#### 5.4.4. Import-related module attributes

The import machinery fills in these attributes on each module object during loading, based on the module's spec, before the loader executes the module.

`__name__`

The `__name__` attribute must be set to the fully qualified name of the module. This name is used to uniquely identify the module in the import system.

`__loader__`

The `__loader__` attribute must be set to the loader object that the import machinery used when loading the module. This is mostly for introspection, but can be used for additional loader-specific functionality, for example getting data associated with a loader.

`__package__`

The module's `__package__` attribute must be set. Its value must be a string, but it can be the same value as its `__name__`. When the module is a package, its

`__package__` value should be set to its `__name__`. When the module is not a package, `__package__` should be set to the empty string for top-level modules, or for submodules, to the parent package's name. See [PEP 366](https://peps.python.org/pep-0366/) [https://peps.python.org/pep-0366/] for further details.

This attribute is used instead of `__name__` to calculate explicit relative imports for main modules, as defined in [PEP 366](https://peps.python.org/pep-0366/) [https://peps.python.org/pep-0366/]. It is expected to have the same value as `__spec__.parent`.

*Changed in version 3.6:* The value of `__package__` is expected to be the same as `__spec__.parent`.

## `__spec__`

The `__spec__` attribute must be set to the module spec that was used when importing the module. Setting `__spec__` appropriately applies equally to [modules initialized during interpreter startup](#). The one exception is `__main__`, where `__spec__` is [set to None in some cases](#).

When `__package__` is not defined, `__spec__.parent` is used as a fallback.

*New in version 3.4.*

*Changed in version 3.6:* `__spec__.parent` is used as a fallback when `__package__` is not defined.

## `__path__`

If the module is a package (either regular or namespace), the module object's `__path__` attribute must be set. The value must be iterable, but may be empty if `__path__` has no further significance. If `__path__` is not empty, it must produce strings when iterated over. More details on the semantics of `__path__` are given [below](#).

Non-package modules should not have a `__path__` attribute.

`__file__`

`__cached__`

`__file__` is optional (if set, value must be a string). It indicates the pathname of the file from which the module was loaded (if loaded from a file), or the pathname of the shared library file for extension modules loaded dynamically from a shared library. It might be missing for certain types of modules, such as C modules that are statically linked into the interpreter, and the import system may opt to leave it unset if it has no semantic meaning (e.g. a module loaded from a database).

If `__file__` is set then the `__cached__` attribute might also be set, which is the path to any compiled version of the code (e.g. byte-compiled file). The file does not need to exist to set this attribute; the path can simply point to where the compiled file would exist (see [PEP 3147](https://peps.python.org/pep-3147/) [https://peps.python.org/pep-3147/]).

Note that `__cached__` may be set even if `__file__` is not set. However, that scenario is quite atypical. Ultimately, the loader is what makes use of the module spec provided by the finder (from which `__file__` and `__cached__` are derived). So if a loader can load from a cached module but otherwise does not load from a file, that atypical scenario may be appropriate.

### 5.4.5. module.`__path__`

By definition, if a module has a `__path__` attribute, it is a package.

A package's `__path__` attribute is used during imports of its subpackages. Within the import machinery, it functions much the same as `sys.path`, i.e. providing a list of locations to search for modules during import. However, `__path__` is typically much more constrained than `sys.path`.

`__path__` must be an iterable of strings, but it may be empty. The

same rules used for `sys.path` also apply to a package's `__path__`, and `sys.path_hooks` (described below) are consulted when traversing a package's `__path__`.

A package's `__init__.py` file may set or alter the package's `__path__` attribute, and this was typically the way namespace packages were implemented prior to [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/]. With the adoption of [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/], namespace packages no longer need to supply `__init__.py` files containing only `__path__` manipulation code; the import machinery automatically sets `__path__` correctly for the namespace package.

### 5.4.6. Module reprs

By default, all modules have a usable repr, however depending on the attributes set above, and in the module's spec, you can more explicitly control the repr of module objects.

If the module has a spec (`__spec__`), the import machinery will try to generate a repr from it. If that fails or there is no spec, the import system will craft a default repr using whatever information is available on the module. It will try to use the `module.__name__`, `module.__file__`, and `module.__loader__` as input into the repr, with defaults for whatever information is missing.

Here are the exact rules used:

- If the module has a `__spec__` attribute, the information in the spec is used to generate the repr. The “name”, “loader”, “origin”, and “has\_location” attributes are consulted.
- If the module has a `__file__` attribute, this is used as part of the module's repr.
- If the module has no `__file__` but does have a `__loader__` that is not `None`, then the loader's repr is used as part of the module's repr.
- Otherwise, just use the module's `__name__` in the repr.

*Changed in version 3.4:* Use of `loader.module_repr()` has been deprecated and the module spec is now used by the import machinery to generate a module repr.

For backward compatibility with Python 3.3, the module repr will be generated by calling the loader's `module_repr()` method, if defined, before trying either approach described above. However, the method is deprecated.

*Changed in version 3.10:* Calling `module_repr()` now occurs after trying to use a module's `__spec__` attribute but before falling back on `__file__`. Use of `module_repr()` is slated to stop in Python 3.12.

### 5.4.7. Cached bytecode invalidation

Before Python loads cached bytecode from a `.pyc` file, it checks whether the cache is up-to-date with the source `.py` file. By default, Python does this by storing the source's last-modified timestamp and size in the cache file when writing it. At runtime, the import system then validates the cache file by checking the stored metadata in the cache file against the source's metadata.

Python also supports “hash-based” cache files, which store a hash of the source file's contents rather than its metadata. There are two variants of hash-based `.pyc` files: checked and unchecked. For checked hash-based `.pyc` files, Python validates the cache file by hashing the source file and comparing the resulting hash with the hash in the cache file. If a checked hash-based cache file is found to be invalid, Python regenerates it and writes a new checked hash-based cache file. For unchecked hash-based `.pyc` files, Python simply assumes the cache file is valid if it exists. Hash-based `.pyc` files validation behavior may be overridden with the `--check-hash-based-pycs` flag.

*Changed in version 3.7:* Added hash-based `.pyc` files. Previously, Python only supported timestamp-based invalidation of bytecode caches.

## 5.5. The Path Based Finder

As mentioned previously, Python comes with several default meta path finders. One of these, called the [path based finder](#) ([PathFinder](#)), searches an [import path](#), which contains a list of [path entries](#). Each path entry names a location to search for modules.

The path based finder itself doesn't know how to import anything. Instead, it traverses the individual path entries, associating each of them with a path entry finder that knows how to handle that particular kind of path.

The default set of path entry finders implement all the semantics for finding modules on the file system, handling special file types such as Python source code (`.py` files), Python byte code (`.pyc` files) and shared libraries (e.g. `.so` files). When supported by the [zipimport](#) module in the standard library, the default path entry finders also handle loading all of these file types (other than shared libraries) from zipfiles.

Path entries need not be limited to file system locations. They can refer to URLs, database queries, or any other location that can be specified as a string.

The path based finder provides additional hooks and protocols so that you can extend and customize the types of searchable path entries. For example, if you wanted to support path entries as network URLs, you could write a hook that implements HTTP semantics to find modules on the web. This hook (a callable) would return a [path entry finder](#) supporting the protocol described below, which was then used to get a loader for the module from the web.

A word of warning: this section and the previous both use the term *finder*, distinguishing between them by using the terms [meta path finder](#) and [path entry finder](#). These two types of finders are very similar, support similar protocols, and function in similar ways during the import process, but it's important to keep in mind that they are subtly different. In particular, meta path finders operate at the beginning of the import process, as keyed off the [sys.meta\\_path](#) traversal.

By contrast, path entry finders are in a sense an implementation

detail of the path based finder, and in fact, if the path based finder were to be removed from `sys.meta_path`, none of the path entry finder semantics would be invoked.

### 5.5.1. Path entry finders

The [path based finder](#) is responsible for finding and loading Python modules and packages whose location is specified with a string [path entry](#). Most path entries name locations in the file system, but they need not be limited to this.

As a meta path finder, the [path based finder](#) implements the [find\\_spec\(\)](#) protocol previously described, however it exposes additional hooks that can be used to customize how modules are found and loaded from the [import path](#).

Three variables are used by the [path based finder](#), `sys.path`, `sys.path_hooks` and `sys.path_importer_cache`. The `__path__` attributes on package objects are also used. These provide additional ways that the import machinery can be customized.

`sys.path` contains a list of strings providing search locations for modules and packages. It is initialized from the `PYTHONPATH` environment variable and various other installation- and implementation-specific defaults. Entries in `sys.path` can name directories on the file system, zip files, and potentially other “locations” (see the [site](#) module) that should be searched for modules, such as URLs, or database queries. Only strings should be present on `sys.path`; all other data types are ignored.

The [path based finder](#) is a [meta path finder](#), so the import machinery begins the [import path](#) search by calling the path based finder’s [find\\_spec\(\)](#) method as described previously. When the `path` argument to [find\\_spec\(\)](#) is given, it will be a list of string paths to traverse - typically a package’s `__path__` attribute for an import within that package. If the `path` argument is `None`, this indicates a top level import and `sys.path` is used.

The path based finder iterates over every entry in the search path, and for each of these, looks for an appropriate [path entry finder](#)

(`PathEntryFinder`) for the path entry. Because this can be an expensive operation (e.g. there may be `stat()` call overheads for this search), the path based finder maintains a cache mapping path entries to path entry finders. This cache is maintained in `sys.path_importer_cache` (despite the name, this cache actually stores finder objects rather than being limited to `importer` objects). In this way, the expensive search for a particular `path entry` location's `path entry finder` need only be done once. User code is free to remove cache entries from `sys.path_importer_cache` forcing the path based finder to perform the path entry search again 3.

If the path entry is not present in the cache, the path based finder iterates over every callable in `sys.path_hooks`. Each of the `path entry hooks` in this list is called with a single argument, the path entry to be searched. This callable may either return a `path entry finder` that can handle the path entry, or it may raise `ImportError`. An `ImportError` is used by the path based finder to signal that the hook cannot find a `path entry finder` for that `path entry`. The exception is ignored and `import path` iteration continues. The hook should expect either a string or bytes object; the encoding of bytes objects is up to the hook (e.g. it may be a file system encoding, UTF-8, or something else), and if the hook cannot decode the argument, it should raise `ImportError`.

If `sys.path_hooks` iteration ends with no `path entry finder` being returned, then the path based finder's `find_spec()` method will store `None` in `sys.path_importer_cache` (to indicate that there is no finder for this path entry) and return `None`, indicating that this `meta path finder` could not find the module.

If a `path entry finder` is returned by one of the `path entry hook` callables on `sys.path_hooks`, then the following protocol is used to ask the finder for a module spec, which is then used when loading the module.

The current working directory – denoted by an empty string – is handled slightly differently from other entries on `sys.path`. First, if the current working directory is found to not exist, no value is stored in `sys.path_importer_cache`. Second, the value for the current working directory is looked up fresh for each module

lookup. Third, the path used for `sys.path_importer_cache` and returned by `importlib.machinery.PathFinder.find_spec()` will be the actual current working directory and not the empty string.

### 5.5.2. Path entry finder protocol

In order to support imports of modules and initialized packages and also to contribute portions to namespace packages, path entry finders must implement the `find_spec()` method.

`find_spec()` takes two arguments: the fully qualified name of the module being imported, and the (optional) target module. `find_spec()` returns a fully populated spec for the module. This spec will always have “loader” set (with one exception).

To indicate to the import machinery that the spec represents a namespace [portion](#), the path entry finder sets “submodule\_search\_locations” to a list containing the portion.

*Changed in version 3.4:* `find_spec()` replaced `find_loader()` and `find_module()`, both of which are now deprecated, but will be used if `find_spec()` is not defined.

Older path entry finders may implement one of these two deprecated methods instead of `find_spec()`. The methods are still respected for the sake of backward compatibility. However, if `find_spec()` is implemented on the path entry finder, the legacy methods are ignored.

`find_loader()` takes one argument, the fully qualified name of the module being imported. `find_loader()` returns a 2-tuple where the first item is the loader and the second item is a namespace [portion](#).

For backwards compatibility with other implementations of the import protocol, many path entry finders also support the same, traditional `find_module()` method that meta path finders support. However path entry finder `find_module()` methods are never called with a `path` argument (they are expected to record the appropriate path information from the initial call to the path

hook).

The `find_module()` method on path entry finders is deprecated, as it does not allow the path entry finder to contribute portions to namespace packages. If both `find_loader()` and `find_module()` exist on a path entry finder, the import system will always call `find_loader()` in preference to `find_module()`.

*Changed in version 3.10:* Calls to `find_module()` and `find_loader()` by the import system will raise `ImportWarning`.

## 5.6. Replacing the standard import system

The most reliable mechanism for replacing the entire import system is to delete the default contents of `sys.meta_path`, replacing them entirely with a custom meta path hook.

If it is acceptable to only alter the behaviour of import statements without affecting other APIs that access the import system, then replacing the builtin `__import__()` function may be sufficient. This technique may also be employed at the module level to only alter the behaviour of import statements within that module.

To selectively prevent the import of some modules from a hook early on the meta path (rather than disabling the standard import system entirely), it is sufficient to raise `ModuleNotFoundError` directly from `find_spec()` instead of returning `None`. The latter indicates that the meta path search should continue, while raising an exception terminates it immediately.

## 5.7. Package Relative Imports

Relative imports use leading dots. A single leading dot indicates a relative import, starting with the current package. Two or more leading dots indicate a relative import to the parent(s) of the current package, one level per dot after the first. For example, given

the following package layout:

```
package/  
    __init__.py  
    subpackage1/  
        __init__.py  
        moduleX.py  
        moduleY.py  
    subpackage2/  
        __init__.py  
        moduleZ.py  
    moduleA.py
```

In either `subpackage1/moduleX.py` or `subpackage1/__init__.py`, the following are valid relative imports:

```
from .moduleY import spam  
from .moduleY import spam as ham  
from . import moduleY  
from ..subpackage1 import moduleY  
from ..subpackage2.moduleZ import eggs  
from ..moduleA import foo
```

Absolute imports may use either the `import <>` or `from <>` `import <>` syntax, but relative imports may only use the second form; the reason for this is that:

```
import XXX.YYY.ZZZ
```

should expose `XXX.YYY.ZZZ` as a usable expression, but `.moduleY` is not a valid expression.

## 5.8. Special considerations for `__main__`

The `__main__` module is a special case relative to Python's import system. As noted [elsewhere](#), the `__main__` module is directly initialized at interpreter startup, much like `sys` and `builtins`. However, unlike those two, it doesn't strictly qualify as a built-in module. This is because the manner in which `__main__` is initialized depends on the flags and other options with which the

interpreter is invoked.

### 5.8.1. `__main__.__spec__`

Depending on how `__main__` is initialized, `__main__.__spec__` gets set appropriately or to `None`.

When Python is started with the `-m` option, `__spec__` is set to the module spec of the corresponding module or package. `__spec__` is also populated when the `__main__` module is loaded as part of executing a directory, zipfile or other `sys.path` entry.

In the remaining cases `__main__.__spec__` is set to `None`, as the code used to populate the `__main__` does not correspond directly with an importable module:

- interactive prompt
- `-c` option
- running from stdin
- running directly from a source or bytecode file

Note that `__main__.__spec__` is always `None` in the last case, *even if* the file could technically be imported directly as a module instead. Use the `-m` switch if valid module metadata is desired in `__main__`.

Note also that even when `__main__` corresponds with an importable module and `__main__.__spec__` is set accordingly, they're still considered *distinct* modules. This is due to the fact that blocks guarded by `if __name__ == "__main__":` checks only execute when the module is used to populate the `__main__` namespace, and not during normal import.

## 5.9. References

The import machinery has evolved considerably since Python's early days. The original [specification for packages](https://www.python.org/doc/essays/packages/) [https://www.python.org/doc/essays/packages/] is still available to read, although some details have changed since the writing of that document.

The original specification for `sys.meta_path` was [PEP 302](https://peps.python.org/pep-302/) [https://peps.python.org/pep-302/], with subsequent extension in [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/].

[PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/] introduced `namespace packages` for Python 3.3. [PEP 420](https://peps.python.org/pep-0420/) [https://peps.python.org/pep-0420/] also introduced the `find_loader()` protocol as an alternative to `find_module()`.

[PEP 366](https://peps.python.org/pep-0366/) [https://peps.python.org/pep-0366/] describes the addition of the `__package__` attribute for explicit relative imports in main modules.

[PEP 328](https://peps.python.org/pep-0328/) [https://peps.python.org/pep-0328/] introduced absolute and explicit relative imports and initially proposed `__name__` for semantics [PEP 366](https://peps.python.org/pep-0366/) [https://peps.python.org/pep-0366/] would eventually specify for `__package__`.

[PEP 338](https://peps.python.org/pep-0338/) [https://peps.python.org/pep-0338/] defines executing modules as scripts.

[PEP 451](https://peps.python.org/pep-0451/) [https://peps.python.org/pep-0451/] adds the encapsulation of per-module import state in spec objects. It also off-loads most of the boilerplate responsibilities of loaders back onto the import machinery. These changes allow the deprecation of several APIs in the import system and also addition of new methods to finders and loaders.

## Footnotes

1

See `types.ModuleType`.

2

The `importlib` implementation avoids using the return value directly. Instead, it gets the module object by looking the module name up in `sys.modules`. The indirect effect of this is that an imported module may replace itself in `sys.modules`. This is implementation-specific behavior that is

not guaranteed to work in other Python implementations.

3

In legacy code, it is possible to find instances of `imp.NullImporter` in the `sys.path_importer_cache`. It is recommended that code be changed to use `None` instead. See [Porting Python code](#) for more details.

## 6. Expressions

This chapter explains the meaning of the elements of expressions in Python.

**Syntax Notes:** In this and the following chapters, extended BNF notation will be used to describe syntax, not lexical analysis. When (one alternative of) a syntax rule has the form

**name ::= othername**

and no semantics are given, the semantics of this form of `name` are the same as for `othername`.

### 6.1. Arithmetic conversions

When a description of an arithmetic operator below uses the phrase “the numeric arguments are converted to a common type”, this means that the operator implementation for built-in types works as follows:

- If either argument is a complex number, the other is converted to complex;
- otherwise, if either argument is a floating point number, the other is converted to floating point;
- otherwise, both must be integers and no conversion is necessary.

Some additional rules apply for certain operators (e.g., a string as a left argument to the ‘%’ operator). Extensions must define their own conversion behavior.

### 6.2. Atoms

Atoms are the most basic elements of expressions. The simplest atoms are identifiers or literals. Forms enclosed in parentheses, brackets or braces are also categorized syntactically as atoms. The syntax for atoms is:

```
atom      ::= identifier | literal | enclosure
enclosure ::= parenth_form | list_display | dict_display
           | generator_expression | yield_atom
```

### 6.2.1. Identifiers (Names)

An identifier occurring as an atom is a name. See section [Identifiers and keywords](#) for lexical definition and section [Naming and binding](#) for documentation of naming and binding.

When the name is bound to an object, evaluation of the atom yields that object. When a name is not bound, an attempt to evaluate it raises a [NameError](#) exception.

**Private name mangling:** When an identifier that textually occurs in a class definition begins with two or more underscore characters and does not end in two or more underscores, it is considered a *private name* of that class. Private names are transformed to a longer form before code is generated for them. The transformation inserts the class name, with leading underscores removed and a single underscore inserted, in front of the name. For example, the identifier `__spam` occurring in a class named `Ham` will be transformed to `_Ham__spam`. This transformation is independent of the syntactical context in which the identifier is used. If the transformed name is extremely long (longer than 255 characters), implementation defined truncation may happen. If the class name consists only of underscores, no transformation is done.

### 6.2.2. Literals

Python supports string and bytes literals and various numeric literals:

```
literal ::= stringliteral | bytesliteral  
           | integer | floatnumber | imagnumber
```

Evaluation of a literal yields an object of the given type (string, bytes, integer, floating point number, complex number) with the given value. The value may be approximated in the case of floating point and imaginary (complex) literals. See section [Literals](#) for details.

All literals correspond to immutable data types, and hence the object's identity is less important than its value. Multiple evaluations of literals with the same value (either the same occurrence in the program text or a different occurrence) may obtain the same object or a different object with the same value.

### 6.2.3. Parenthesized forms

A parenthesized form is an optional expression list enclosed in parentheses:

```
parenth_form ::= " (" [starred_expression] ") "
```

A parenthesized expression list yields whatever that expression list yields: if the list contains at least one comma, it yields a tuple; otherwise, it yields the single expression that makes up the expression list.

An empty pair of parentheses yields an empty tuple object. Since tuples are immutable, the same rules as for literals apply (i.e., two occurrences of the empty tuple may or may not yield the same object).

Note that tuples are not formed by the parentheses, but rather by use of the comma. The exception is the empty tuple, for which parentheses *are* required — allowing unparenthesized “nothing” in expressions would cause ambiguities and allow common typos to pass uncaught.

### 6.2.4. Displays for lists, sets and dictionaries

For constructing a list, a set or a dictionary Python provides special syntax called “displays”, each of them in two flavors:

- either the container contents are listed explicitly, or
- they are computed via a set of looping and filtering instructions, called a *comprehension*.

Common syntax elements for comprehensions are:

```
comprehension ::= assignment_expression comp_for
comp_for      ::= ["async"] "for" target_list "in" or_test
comp_iter     ::= comp_for | comp_if
comp_if       ::= "if" or_test [comp_iter]
```

The comprehension consists of a single expression followed by at least one **for** clause and zero or more **for** or **if** clauses. In this case, the elements of the new container are those that would be produced by considering each of the **for** or **if** clauses a block, nesting from left to right, and evaluating the expression to produce an element each time the innermost block is reached.

However, aside from the iterable expression in the leftmost **for** clause, the comprehension is executed in a separate implicitly nested scope. This ensures that names assigned to in the target list don’t “leak” into the enclosing scope.

The iterable expression in the leftmost **for** clause is evaluated directly in the enclosing scope and then passed as an argument to the implicitly nested scope. Subsequent **for** clauses and any filter condition in the leftmost **for** clause cannot be evaluated in the enclosing scope as they may depend on the values obtained from the leftmost iterable. For example: `[x*y for x in range(10) for y in range(x, x+10)]`.

To ensure the comprehension always results in a container of the appropriate type, `yield` and `yield from` expressions are prohibited in the implicitly nested scope.

Since Python 3.6, in an **async def** function, an **async for** clause may be used to iterate over a **asynchronous iterator**. A

comprehension in an **async def** function may consist of either a **for** or **async for** clause following the leading expression, may contain additional **for** or **async for** clauses, and may also use **await** expressions. If a comprehension contains either **async for** clauses or **await** expressions or other asynchronous comprehensions it is called an *asynchronous comprehension*. An asynchronous comprehension may suspend the execution of the coroutine function in which it appears. See also [PEP 530](https://peps.python.org/pep-0530/) [https://peps.python.org/pep-0530/].

*New in version 3.6:* Asynchronous comprehensions were introduced.

*Changed in version 3.8:* `yield` and `yield from` prohibited in the implicitly nested scope.

*Changed in version 3.11:* Asynchronous comprehensions are now allowed inside comprehensions in asynchronous functions. Outer comprehensions implicitly become asynchronous.

## 6.2.5. List displays

A list display is a possibly empty series of expressions enclosed in square brackets:

```
list_display ::= "[" [starred_list | comprehension] "]"
```

A list display yields a new list object, the contents being specified by either a list of expressions or a comprehension. When a comma-separated list of expressions is supplied, its elements are evaluated from left to right and placed into the list object in that order. When a comprehension is supplied, the list is constructed from the elements resulting from the comprehension.

## 6.2.6. Set displays

A set display is denoted by curly braces and distinguishable from dictionary displays by the lack of colons separating keys and values:

```
set_display ::= "{" (starred_list | comprehension) "}"
```

A set display yields a new mutable set object, the contents being specified by either a sequence of expressions or a comprehension. When a comma-separated list of expressions is supplied, its elements are evaluated from left to right and added to the set object. When a comprehension is supplied, the set is constructed from the elements resulting from the comprehension.

An empty set cannot be constructed with `{ }`; this literal constructs an empty dictionary.

### 6.2.7. Dictionary displays

A dictionary display is a possibly empty series of dict items (key/value pairs) enclosed in curly braces:

```
dict_display      ::= " {" [dict_item_list | dict_comprehension] "}"
dict_item_list    ::= dict_item ("," dict_item)* ["," dict_item]
dict_item         ::= expression ":" expression | "**" expression
dict_comprehension ::= expression ":" expression comp_for
```

A dictionary display yields a new dictionary object.

If a comma-separated sequence of dict items is given, they are evaluated from left to right to define the entries of the dictionary: each key object is used as a key into the dictionary to store the corresponding value. This means that you can specify the same key multiple times in the dict item list, and the final dictionary’s value for that key will be the last one given.

A double asterisk `**` denotes *dictionary unpacking*. Its operand must be a [mapping](#). Each mapping item is added to the new dictionary. Later values replace values already set by earlier dict items and earlier dictionary unpackings.

*New in version 3.5:* Unpacking into dictionary displays, originally proposed by [PEP 448](#) [<https://peps.python.org/pep-0448/>].

A dict comprehension, in contrast to list and set comprehensions, needs two expressions separated with a colon followed by the usual “for” and “if” clauses. When the comprehension is run, the resulting

key and value elements are inserted in the new dictionary in the order they are produced.

Restrictions on the types of the key values are listed earlier in section [The standard type hierarchy](#). (To summarize, the key type should be [hashable](#), which excludes all mutable objects.) Clashes between duplicate keys are not detected; the last value (textually rightmost in the display) stored for a given key value prevails.

*Changed in version 3.8:* Prior to Python 3.8, in dict comprehensions, the evaluation order of key and value was not well-defined. In CPython, the value was evaluated before the key. Starting with 3.8, the key is evaluated before the value, as proposed by [PEP 572](#) [<https://peps.python.org/pep-0572/>].

### 6.2.8. Generator expressions

A generator expression is a compact generator notation in parentheses:

```
generator_expression ::= " (" expression comp_for " ) "
```

A generator expression yields a new generator object. Its syntax is the same as for comprehensions, except that it is enclosed in parentheses instead of brackets or curly braces.

Variables used in the generator expression are evaluated lazily when the `__next__()` method is called for the generator object (in the same fashion as normal generators). However, the iterable expression in the leftmost **for** clause is immediately evaluated, so that an error produced by it will be emitted at the point where the generator expression is defined, rather than at the point where the first value is retrieved. Subsequent **for** clauses and any filter condition in the leftmost **for** clause cannot be evaluated in the enclosing scope as they may depend on the values obtained from the leftmost iterable. For example: `(x*y for x in range(10) for y in range(x, x+10))`.

The parentheses can be omitted on calls with only one argument. See section [Calls](#) for details.

To avoid interfering with the expected operation of the generator expression itself, `yield` and `yield from` expressions are prohibited in the implicitly defined generator.

If a generator expression contains either **`async for`** clauses or **`await`** expressions it is called an *asynchronous generator expression*. An asynchronous generator expression returns a new asynchronous generator object, which is an asynchronous iterator (see [Asynchronous Iterators](#)).

*New in version 3.6:* Asynchronous generator expressions were introduced.

*Changed in version 3.7:* Prior to Python 3.7, asynchronous generator expressions could only appear in **`async def`** coroutines. Starting with 3.7, any function can use asynchronous generator expressions.

*Changed in version 3.8:* `yield` and `yield from` prohibited in the implicitly nested scope.

## 6.2.9. Yield expressions

```
yield_atom      ::= "(" yield_expression ")"
yield_expression ::= "yield" [expression_list | "from"
```

The `yield` expression is used when defining a [generator](#) function or an [asynchronous generator](#) function and thus can only be used in the body of a function definition. Using a `yield` expression in a function's body causes that function to be a generator function, and using it in an **`async def`** function's body causes that coroutine function to be an asynchronous generator function. For example:

```
def gen(): # defines a generator function
    yield 123
```

```
async def agen(): # defines an asynchronous generator fu
    yield 123
```

Due to their side effects on the containing scope, `yield` expressions are not permitted as part of the implicitly defined

scopes used to implement comprehensions and generator expressions.

*Changed in version 3.8:* Yield expressions prohibited in the implicitly nested scopes used to implement comprehensions and generator expressions.

Generator functions are described below, while asynchronous generator functions are described separately in section [Asynchronous generator functions](#).

When a generator function is called, it returns an iterator known as a generator. That generator then controls the execution of the generator function. The execution starts when one of the generator's methods is called. At that time, the execution proceeds to the first yield expression, where it is suspended again, returning the value of `expression_list` to the generator's caller, or `None` if `expression_list` is omitted. By suspended, we mean that all local state is retained, including the current bindings of local variables, the instruction pointer, the internal evaluation stack, and the state of any exception handling. When the execution is resumed by calling one of the generator's methods, the function can proceed exactly as if the yield expression were just another external call. The value of the yield expression after resuming depends on the method which resumed the execution. If `__next__()` is used (typically via either a `for` or the `next()` builtin) then the result is `None`. Otherwise, if `send()` is used, then the result will be the value passed in to that method.

All of this makes generator functions quite similar to coroutines; they yield multiple times, they have more than one entry point and their execution can be suspended. The only difference is that a generator function cannot control where the execution should continue after it yields; the control is always transferred to the generator's caller.

Yield expressions are allowed anywhere in a `try` construct. If the generator is not resumed before it is finalized (by reaching a zero reference count or by being garbage collected), the generator-iterator's `close()` method will be called, allowing any pending `finally` clauses to execute.

When `yield from <expr>` is used, the supplied expression must be an iterable. The values produced by iterating that iterable are passed directly to the caller of the current generator's methods. Any values passed in with `send()` and any exceptions passed in with `throw()` are passed to the underlying iterator if it has the appropriate methods. If this is not the case, then `send()` will raise `AttributeError` or `TypeError`, while `throw()` will just raise the passed in exception immediately.

When the underlying iterator is complete, the `value` attribute of the raised `StopIteration` instance becomes the value of the yield expression. It can be either set explicitly when raising `StopIteration`, or automatically when the subiterator is a generator (by returning a value from the subgenerator).

*Changed in version 3.3:* Added `yield from <expr>` to delegate control flow to a subiterator.

The parentheses may be omitted when the yield expression is the sole expression on the right hand side of an assignment statement.

coroutine functions.

### 6.2.9.1. Generator-iterator methods

This subsection describes the methods of a generator iterator. They can be used to control the execution of a generator function.

Note that calling any of the generator methods below when the generator is already executing raises a **ValueError** exception.

`generator.__next__()`

Starts the execution of a generator function or resumes it at the last executed yield expression. When a generator function is resumed with a `__next__()` method, the current yield expression always evaluates to **None**. The execution then continues to the next yield expression, where the generator is suspended again, and the value of the `expression_list` is returned to `__next__()`'s caller. If the generator exits without yielding another value, a **StopIteration** exception is raised.

This method is normally called implicitly, e.g. by a **for** loop, or by the built-in `next()` function.

`generator.send(value)`

Resumes the execution and “sends” a value into the generator function. The *value* argument becomes the result of the current yield expression. The `send()` method returns the next value yielded by the generator, or raises **StopIteration** if the generator exits without yielding another value. When `send()` is called to start the generator, it must be called with **None** as the argument, because there is no yield expression that could receive the value.

`generator.throw(value)`

`generator.throw(type[, value[, traceback]])`

Raises an exception at the point where the generator was paused, and returns the next value yielded by the generator

function. If the generator exits without yielding another value, a `StopIteration` exception is raised. If the generator function does not catch the passed-in exception, or raises a different exception, then that exception propagates to the caller.

In typical use, this is called with a single exception instance similar to the way the `raise` keyword is used.

For backwards compatibility, however, the second signature is supported, following a convention from older versions of Python. The *type* argument should be an exception class, and *value* should be an exception instance. If the *value* is not provided, the *type* constructor is called to get an instance. If *traceback* is provided, it is set on the exception, otherwise any existing `__traceback__` attribute stored in *value* may be cleared.

`generator.close()`

Raises a `GeneratorExit` at the point where the generator function was paused. If the generator function then exits gracefully, is already closed, or raises `GeneratorExit` (by not catching the exception), `close` returns to its caller. If the generator yields a value, a `RuntimeError` is raised. If the generator raises any other exception, it is propagated to the caller. `close()` does nothing if the generator has already exited due to an exception or normal exit.

### 6.2.9.2. Examples

Here is a simple example that demonstrates the behavior of generators and generator functions:

```
>>> def echo(value=None):
...     print("Execution starts when 'next()' is called")
...     try:
...         while True:
...             try:
...                 value = (yield value)
```

```

...             except Exception as e:
...                 value = e
...         finally:
...             print("Don't forget to clean up when 'close()' is called.")
...
>>> generator = echo(1)
>>> print(next(generator))
Execution starts when 'next()' is called for the first time.
1
>>> print(next(generator))
None
>>> print(generator.send(2))
2
>>> generator.throw(TypeError, "spam")
TypeError('spam',)
>>> generator.close()
Don't forget to clean up when 'close()' is called.

```

For examples using `yield from`, see [PEP 380: Syntax for Delegating to a Subgenerator](#) in “What’s New in Python.”

### 6.2.9.3. Asynchronous generator functions

The presence of a `yield` expression in a function or method defined using **`async def`** further defines the function as an **asynchronous generator** function.

When an asynchronous generator function is called, it returns an asynchronous iterator known as an asynchronous generator object. That object then controls the execution of the generator function. An asynchronous generator object is typically used in an **`async for`** statement in a coroutine function analogously to how a generator object would be used in a **`for`** statement.

Calling one of the asynchronous generator’s methods returns an **awaitable** object, and the execution starts when this object is awaited on. At that time, the execution proceeds to the first `yield` expression, where it is suspended again, returning the value of **`expression_list`** to the awaiting coroutine. As with a generator, suspension means that all local state is retained, including the

current bindings of local variables, the instruction pointer, the internal evaluation stack, and the state of any exception handling. When the execution is resumed by awaiting on the next object returned by the asynchronous generator's methods, the function can proceed exactly as if the yield expression were just another external call. The value of the yield expression after resuming depends on the method which resumed the execution. If `__anext__()` is used then the result is `None`. Otherwise, if `asend()` is used, then the result will be the value passed in to that method.

If an asynchronous generator happens to exit early by `break`, the caller task being cancelled, or other exceptions, the generator's async cleanup code will run and possibly raise exceptions or access context variables in an unexpected context—perhaps after the lifetime of tasks it depends, or during the event loop shutdown when the async-generator garbage collection hook is called. To prevent this, the caller must explicitly close the async generator by calling `aclose()` method to finalize the generator and ultimately detach it from the event loop.

In an asynchronous generator function, yield expressions are allowed anywhere in a `try` construct. However, if an asynchronous generator is not resumed before it is finalized (by reaching a zero reference count or by being garbage collected), then a yield expression within a `try` construct could result in a failure to execute pending `finally` clauses. In this case, it is the responsibility of the event loop or scheduler running the asynchronous generator to call the asynchronous generator-iterator's `aclose()` method and run the resulting coroutine object, thus allowing any pending `finally` clauses to execute.

To take care of finalization upon event loop termination, an event loop should define a *finalizer* function which takes an asynchronous generator-iterator and presumably calls `aclose()` and executes the coroutine. This *finalizer* may be registered by calling `sys.set_asyncgen_hooks()`. When first iterated over, an asynchronous generator-iterator will store the registered *finalizer* to be called upon finalization. For a reference example of a *finalizer* method see the implementation of `asyncio.Loop.shutdown_asyncgens` in [Lib/asyncio/](#)

[base\\_events.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_events.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base\_events.py].

The expression `yield from <expr>` is a syntax error when used in an asynchronous generator function.

#### 6.2.9.4. Asynchronous generator-iterator methods

This subsection describes the methods of an asynchronous generator iterator, which are used to control the execution of a generator function.

*coroutine* `agen._anext_()`

Returns an awaitable which when run starts to execute the asynchronous generator or resumes it at the last executed yield expression. When an asynchronous generator function is resumed with an `__anext__()` method, the current yield expression always evaluates to `None` in the returned awaitable, which when run will continue to the next yield expression. The value of the `expression_list` of the yield expression is the value of the `StopIteration` exception raised by the completing coroutine. If the asynchronous generator exits without yielding another value, the awaitable instead raises a `StopAsyncIteration` exception, signalling that the asynchronous iteration has completed.

This method is normally called implicitly by a `async for` loop.

*coroutine* `agen.asend(value)`

Returns an awaitable which when run resumes the execution of the asynchronous generator. As with the `send()` method for a generator, this “sends” a value into the asynchronous generator function, and the `value` argument becomes the result of the current yield expression. The awaitable returned by the `asend()` method will return the next value yielded by the generator as the value of the raised `StopIteration`, or raises `StopAsyncIteration` if the asynchronous generator exits without yielding another value. When

**asend()** is called to start the asynchronous generator, it must be called with **None** as the argument, because there is no yield expression that could receive the value.

*coroutine* agen.athrow(*value*)

*coroutine* agen.athrow(*type*[, *value*[, *traceback*]])

Returns an awaitable that raises an exception of type *type* at the point where the asynchronous generator was paused, and returns the next value yielded by the generator function as the value of the raised **StopIteration** exception. If the asynchronous generator exits without yielding another value, a **StopAsyncIteration** exception is raised by the awaitable. If the generator function does not catch the passed-in exception, or raises a different exception, then when the awaitable is run that exception propagates to the caller of the awaitable.

*coroutine* agen.aclose()

Returns an awaitable that when run will throw a **GeneratorExit** into the asynchronous generator function at the point where it was paused. If the asynchronous generator function then exits gracefully, is already closed, or raises **GeneratorExit** (by not catching the exception), then the returned awaitable will raise a **StopIteration** exception. Any further awaitables returned by subsequent calls to the asynchronous generator will raise a **StopAsyncIteration** exception. If the asynchronous generator yields a value, a **RuntimeError** is raised by the awaitable. If the asynchronous generator raises any other exception, it is propagated to the caller of the awaitable. If the asynchronous generator has already exited due to an exception or normal exit, then further calls to **aclose()** will return an awaitable that does nothing.

## 6.3. Primaries

Primaries represent the most tightly bound operations of the language. Their syntax is:

**primary** ::= **atom** | **attributeref** | **subscription** | **slicing**

### 6.3.1. Attribute references

An attribute reference is a primary followed by a period and a name:

**attributeref** ::= **primary** "." **identifier**

The primary must evaluate to an object of a type that supports attribute references, which most objects do. This object is then asked to produce the attribute whose name is the identifier. This production can be customized by overriding the `__getattr__()` method. If this attribute is not available, the exception `AttributeError` is raised. Otherwise, the type and value of the object produced is determined by the object. Multiple evaluations of the same attribute reference may yield different objects.

### 6.3.2. Subscriptions

The subscription of an instance of a `container class` will generally select an element from the container. The subscription of a `generic class` will generally return a `GenericAlias` object.

**subscription** ::= **primary** "[" **expression\_list** "]"

When an object is subscripted, the interpreter will evaluate the primary and the expression list.

The primary must evaluate to an object that supports subscription. An object may support subscription through defining one or both of `__getitem__()` and `__class_getitem__()`. When the primary is subscripted, the evaluated result of the expression list will be passed to one of these methods. For more details on when `__class_getitem__` is called instead of `__getitem__`, see [\\_\\_class\\_getitem\\_\\_ versus \\_\\_getitem\\_\\_](#).

If the expression list contains at least one comma, it will evaluate to a **tuple** containing the items of the expression list. Otherwise, the expression list will evaluate to the value of the list's sole member.

For built-in objects, there are two types of objects that support subscription via `__getitem__()`:

1. Mappings. If the primary is a **mapping**, the expression list must evaluate to an object whose value is one of the keys of the mapping, and the subscription selects the value in the mapping that corresponds to that key. An example of a builtin mapping class is the **dict** class.
2. Sequences. If the primary is a **sequence**, the expression list must evaluate to an **int** or a **slice** (as discussed in the following section). Examples of builtin sequence classes include the **str**, **list** and **tuple** classes.

The formal syntax makes no special provision for negative indices in **sequences**. However, built-in sequences all provide a `__getitem__()` method that interprets negative indices by adding the length of the sequence to the index so that, for example, `x[-1]` selects the last item of `x`. The resulting value must be a nonnegative integer less than the number of items in the sequence, and the subscription selects the item whose index is that value (counting from zero). Since the support for negative indices and slicing occurs in the object's `__getitem__()` method, subclasses overriding this method will need to explicitly add that support.

A **string** is a special kind of sequence whose items are *characters*. A character is not a separate data type but a string of exactly one character.

### 6.3.3. Slicings

A slicing selects a range of items in a sequence object (e.g., a string, tuple or list). Slicings may be used as expressions or as targets in assignment or **del** statements. The syntax for a slicing:

```
slicing      ::= primary "[" slice_list "]"
slice_list   ::= slice_item ("," slice_item)* [","]
```

```

keywords_arguments ::= ("," " *" expression | "," " keyword_item | " " *" expression
keyword_item       ::= identifier "=" expression

```

An optional trailing comma may be present after the positional and keyword arguments but does not affect the semantics.

The primary must evaluate to a callable object (user-defined functions, built-in functions, methods of built-in objects, class objects, methods of class instances, and all objects having a `__call__()` method are callable). All argument expressions are evaluated before the call is attempted. Please refer to section [Function definitions](#) for the syntax of formal [parameter](#) lists.

If keyword arguments are present, they are first converted to positional arguments, as follows. First, a list of unfilled slots is created for the formal parameters. If there are *N* positional arguments, they are placed in the first *N* slots. Next, for each keyword argument, the identifier is used to determine the corresponding slot (if the identifier is the same as the first formal parameter name, the first slot is used, and so on). If the slot is already filled, a [TypeError](#) exception is raised. Otherwise, the argument is placed in the slot, filling it (even if the expression is `None`, it fills the slot). When all arguments have been processed, the slots that are still unfilled are filled with the corresponding default value from the function definition. (Default values are calculated, once, when the function is defined; thus, a mutable object such as a list or dictionary used as default value will be shared by all calls that don't specify an argument value for the corresponding slot; this should usually be avoided.) If there are any unfilled slots for which no default value is specified, a [TypeError](#) exception is raised. Otherwise, the list of filled slots is used as the argument list for the call.

**CPython implementation detail:** An implementation may provide built-in functions whose positional parameters do not have names, even if they are ‘named’ for the purpose of documentation, and which therefore cannot be supplied by keyword. In CPython, this is the case for functions implemented in C that use

`PyArg_ParseTuple()` to parse their arguments.

If there are more positional arguments than there are formal parameter slots, a `TypeError` exception is raised, unless a formal parameter using the syntax `*identifier` is present; in this case, that formal parameter receives a tuple containing the excess positional arguments (or an empty tuple if there were no excess positional arguments).

If any keyword argument does not correspond to a formal parameter name, a `TypeError` exception is raised, unless a formal parameter using the syntax `**identifier` is present; in this case, that formal parameter receives a dictionary containing the excess keyword arguments (using the keywords as keys and the argument values as corresponding values), or a (new) empty dictionary if there were no excess keyword arguments.

If the syntax `*expression` appears in the function call, `expression` must evaluate to an `iterable`. Elements from these iterables are treated as if they were additional positional arguments. For the call `f(x1, x2, *y, x3, x4)`, if `y` evaluates to a sequence `y1, ..., yM`, this is equivalent to a call with  $M + 4$  positional arguments `x1, x2, y1, ..., yM, x3, x4`.

A consequence of this is that although the `*expression` syntax may appear *after* explicit keyword arguments, it is processed *before* the keyword arguments (and any `**expression` arguments – see below). So:

```
>>> def f(a, b):
...     print(a, b)
...
>>> f(b=1, *(2,))
2 1
>>> f(a=1, *(2,))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: f() got multiple values for keyword argument
>>> f(1, *(2,))
1 2
```

It is unusual for both keyword arguments and the `*expression` syntax to be used in the same call, so in practice this confusion does not often arise.

If the syntax `**expression` appears in the function call, `expression` must evaluate to a [mapping](#), the contents of which are treated as additional keyword arguments. If a parameter matching a key has already been given a value (by an explicit keyword argument, or from another unpacking), a [TypeError](#) exception is raised.

When `**expression` is used, each key in this mapping must be a string. Each value from the mapping is assigned to the first formal parameter eligible for keyword assignment whose name is equal to the key. A key need not be a Python identifier (e.g. `"max-temp °F"` is acceptable, although it will not match any formal parameter that could be declared). If there is no match to a formal parameter the key-value pair is collected by the `**` parameter, if there is one, or if there is not, a [TypeError](#) exception is raised.

Formal parameters using the syntax `*identifier` or `**identifier` cannot be used as positional argument slots or as keyword argument names.

*Changed in version 3.5:* Function calls accept any number of `*` and `**` unpackings, positional arguments may follow iterable unpackings (`*`), and keyword arguments may follow dictionary unpackings (`**`). Originally proposed by [PEP 448](#) [<https://peps.python.org/pep-0448/>].

A call always returns some value, possibly `None`, unless it raises an exception. How this value is computed depends on the type of the callable object.

If it is—

a user-defined function:

The code block for the function is executed, passing it the argument list. The first thing the code block will do is bind the formal parameters to the arguments; this is described in section [Function definitions](#). When the code block executes a

**return** statement, this specifies the return value of the function call.

a built-in function or method:

The result is up to the interpreter; see [Built-in Functions](#) for the descriptions of built-in functions and methods.

a class object:

A new instance of that class is returned.

a class instance method:

The corresponding user-defined function is called, with an argument list that is one longer than the argument list of the call: the instance becomes the first argument.

a class instance:

The class must define a `__call__()` method; the effect is then the same as if that method was called.

## 6.4. Await expression

Suspend the execution of [coroutine](#) on an [awaitable](#) object. Can only be used inside a [coroutine function](#).

```
await_expr ::= "await" primary
```

*New in version 3.5.*

## 6.5. The power operator

The power operator binds more tightly than unary operators on its left; it binds less tightly than unary operators on its right. The syntax is:

```
power ::= (await\_expr | primary) ["**" u\_expr]
```

Thus, in an unparenthesized sequence of power and unary

operators, the operators are evaluated from right to left (this does not constrain the evaluation order for the operands): `-1**2` results in `-1`.

The power operator has the same semantics as the built-in `pow()` function, when called with two arguments: it yields its left argument raised to the power of its right argument. The numeric arguments are first converted to a common type, and the result is of that type.

For int operands, the result has the same type as the operands unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, `10**2` returns `100`, but `10** -2` returns `0.01`.

Raising `0.0` to a negative power results in a `ZeroDivisionError`. Raising a negative number to a fractional power results in a `complex` number. (In earlier versions it raised a `ValueError`.)

This operation can be customized using the special `__pow__()` method.

## 6.6. Unary arithmetic and bitwise operations

All unary arithmetic and bitwise operations have the same priority:

`u_expr ::= power | "-" u_expr | "+" u_expr | "~" u_expr`

The unary `-` (minus) operator yields the negation of its numeric argument; the operation can be overridden with the `__neg__()` special method.

The unary `+` (plus) operator yields its numeric argument unchanged; the operation can be overridden with the `__pos__()` special method.

The unary `~` (invert) operator yields the bitwise inversion of its

integer argument. The bitwise inversion of  $x$  is defined as  $-(x+1)$ . It only applies to integral numbers or to custom objects that override the `__invert__()` special method.

In all three cases, if the argument does not have the proper type, a `TypeError` exception is raised.

## 6.7. Binary arithmetic operations

The binary arithmetic operations have the conventional priority levels. Note that some of these operations also apply to certain non-numeric types. Apart from the power operator, there are only two levels, one for multiplicative operators and one for additive operators:

```
m_expr ::= u_expr | m_expr "*" u_expr | m_expr "@" m_expr
          m_expr "//" u_expr | m_expr "/" u_expr |
          m_expr "%" u_expr
a_expr ::= m_expr | a_expr "+" m_expr | a_expr "-" m_expr
```

The `*` (multiplication) operator yields the product of its arguments. The arguments must either both be numbers, or one argument must be an integer and the other must be a sequence. In the former case, the numbers are converted to a common type and then multiplied together. In the latter case, sequence repetition is performed; a negative repetition factor yields an empty sequence.

This operation can be customized using the special `__mul__()` and `__rmul__()` methods.

The `@` (at) operator is intended to be used for matrix multiplication. No builtin Python types implement this operator.

*New in version 3.5.*

The `/` (division) and `//` (floor division) operators yield the quotient of their arguments. The numeric arguments are first converted to a common type. Division of integers yields a float, while floor division of integers results in an integer; the result is

that of mathematical division with the ‘floor’ function applied to the result. Division by zero raises the `ZeroDivisionError` exception.

This operation can be customized using the special `__truediv__()` and `__floordiv__()` methods.

The `%` (modulo) operator yields the remainder from the division of the first argument by the second. The numeric arguments are first converted to a common type. A zero right argument raises the `ZeroDivisionError` exception. The arguments may be floating point numbers, e.g., `3.14%0.7` equals `0.34` (since `3.14` equals `4*0.7 + 0.34`.) The modulo operator always yields a result with the same sign as its second operand (or zero); the absolute value of the result is strictly smaller than the absolute value of the second operand [1](#).

The floor division and modulo operators are connected by the following identity:  $x == (x//y) * y + (x\%y)$ . Floor division and modulo are also connected with the built-in function `divmod()`:  $divmod(x, y) == (x//y, x\%y)$ . [2](#).

In addition to performing the modulo operation on numbers, the `%` operator is also overloaded by string objects to perform old-style string formatting (also known as interpolation). The syntax for string formatting is described in the Python Library Reference, section [printf-style String Formatting](#).

The *modulo* operation can be customized using the special `__mod__()` method.

The floor division operator, the modulo operator, and the `divmod()` function are not defined for complex numbers. Instead, convert to a floating point number using the `abs()` function if appropriate.

The `+` (addition) operator yields the sum of its arguments. The arguments must either both be numbers or both be sequences of the same type. In the former case, the numbers are converted to a common type and then added together. In the latter case, the sequences are concatenated.

This operation can be customized using the special `__add__()` and `__radd__()` methods.

The `-` (subtraction) operator yields the difference of its arguments. The numeric arguments are first converted to a common type.

This operation can be customized using the special `__sub__()` method.

## 6.8. Shifting operations

The shifting operations have lower priority than the arithmetic operations:

```
shift_expr ::= a_expr | shift_expr ("<<" | ">>") a_expr
```

These operators accept integers as arguments. They shift the first argument to the left or right by the number of bits given by the second argument.

This operation can be customized using the special `__lshift__()` and `__rshift__()` methods.

A right shift by  $n$  bits is defined as floor division by `pow(2, n)`. A left shift by  $n$  bits is defined as multiplication with `pow(2, n)`.

## 6.9. Binary bitwise operations

Each of the three bitwise operations has a different priority level:

```
and_expr ::= shift_expr | and_expr "&" shift_expr
xor_expr ::= and_expr | xor_expr "^" and_expr
or_expr  ::= xor_expr | or_expr "|" xor_expr
```

The `&` operator yields the bitwise AND of its arguments, which must be integers or one of them must be a custom object overriding `__and__()` or `__rand__()` special methods.

The `^` operator yields the bitwise XOR (exclusive OR) of its arguments, which must be integers or one of them must be a custom object overriding `__xor__()` or `__rxor__()` special methods.

The `|` operator yields the bitwise (inclusive) OR of its arguments, which must be integers or one of them must be a custom object overriding `__or__()` or `__ror__()` special methods.

## 6.10. Comparisons

Unlike C, all comparison operations in Python have the same priority, which is lower than that of any arithmetic, shifting or bitwise operation. Also unlike C, expressions like `a < b < c` have the interpretation that is conventional in mathematics:

```
comparison      ::= or_expr (comp_operator or_expr) *
comp_operator    ::= "<" | ">" | "==" | ">=" | "<=" | "!="
                  | "is" ["not"] | ["not"] "in"
```

Comparisons yield boolean values: `True` or `False`. Custom *rich comparison methods* may return non-boolean values. In this case Python will call `bool()` on such value in boolean contexts.

Comparisons can be chained arbitrarily, e.g., `x < y <= z` is equivalent to `x < y` and `y <= z`, except that `y` is evaluated only once (but in both cases `z` is not evaluated at all when `x < y` is found to be false).

Formally, if `a, b, c, ..., y, z` are expressions and `op1, op2, ..., opN` are comparison operators, then `a op1 b op2 c ... y opN z` is equivalent to `a op1 b` and `b op2 c` and `... y opN z`, except that each expression is evaluated at most once.

Note that `a op1 b op2 c` doesn't imply any kind of comparison between `a` and `c`, so that, e.g., `x < y > z` is perfectly legal (though perhaps not pretty).

### 6.10.1. Value comparisons

The operators `<`, `>`, `==`, `>=`, `<=`, and `!=` compare the values of two objects. The objects do not need to have the same type.

Chapter [Objects, values and types](#) states that objects have a value (in addition to type and identity). The value of an object is a rather abstract notion in Python: For example, there is no canonical access method for an object's value. Also, there is no requirement that the value of an object should be constructed in a particular way, e.g. comprised of all its data attributes. Comparison operators implement a particular notion of what the value of an object is. One can think of them as defining the value of an object indirectly, by means of their comparison implementation.

Because all types are (direct or indirect) subtypes of [object](#), they inherit the default comparison behavior from [object](#). Types can customize their comparison behavior by implementing *rich comparison methods* like `__lt__()`, described in [Basic customization](#).

The default behavior for equality comparison (`==` and `!=`) is based on the identity of the objects. Hence, equality comparison of instances with the same identity results in equality, and equality comparison of instances with different identities results in inequality. A motivation for this default behavior is the desire that all objects should be reflexive (i.e. `x is y` implies `x == y`).

A default order comparison (`<`, `>`, `<=`, and `>=`) is not provided; an attempt raises [TypeError](#). A motivation for this default behavior is the lack of a similar invariant as for equality.

The behavior of the default equality comparison, that instances with different identities are always unequal, may be in contrast to what types will need that have a sensible definition of object value and value-based equality. Such types will need to customize their comparison behavior, and in fact, a number of built-in types have done that.

The following list describes the comparison behavior of the most important built-in types.

- Numbers of built-in numeric types ([Numeric Types — int](#),

`float`, `complex`) and of the standard library types `fractions.Fraction` and `decimal.Decimal` can be compared within and across their types, with the restriction that complex numbers do not support order comparison. Within the limits of the types involved, they compare mathematically (algorithmically) correct without loss of precision.

The not-a-number values `float('NaN')` and `decimal.Decimal('NaN')` are special. Any ordered comparison of a number to a not-a-number value is false. A counter-intuitive implication is that not-a-number values are not equal to themselves. For example, if `x = float('NaN')`, `3 < x`, `x < 3` and `x == x` are all false, while `x != x` is true. This behavior is compliant with IEEE 754.

- `None` and `NotImplemented` are singletons. **PEP 8** [<https://peps.python.org/pep-0008/>] advises that comparisons for singletons should always be done with `is` or `is not`, never the equality operators.
- Binary sequences (instances of `bytes` or `bytearray`) can be compared within and across their types. They compare lexicographically using the numeric values of their elements.
- Strings (instances of `str`) compare lexicographically using the numerical Unicode code points (the result of the built-in function `ord()`) of their characters. **3**

Strings and binary sequences cannot be directly compared.

- Sequences (instances of `tuple`, `list`, or `range`) can be compared only within each of their types, with the restriction that ranges do not support order comparison. Equality comparison across these types results in inequality, and ordering comparison across these types raises `TypeError`.

Sequences compare lexicographically using comparison of corresponding elements. The built-in containers typically assume identical objects are equal to themselves. That lets

them bypass equality tests for identical objects to improve performance and to maintain their internal invariants.

Lexicographical comparison between built-in collections works as follows:

- For two collections to compare equal, they must be of the same type, have the same length, and each pair of corresponding elements must compare equal (for example, `[1, 2] == (1, 2)` is false because the type is not the same).
- Collections that support order comparison are ordered the same as their first unequal elements (for example, `[1, 2, x] <= [1, 2, y]` has the same value as `x <= y`). If a corresponding element does not exist, the shorter collection is ordered first (for example, `[1, 2] < [1, 2, 3]` is true).
- Mappings (instances of `dict`) compare equal if and only if they have equal `(key, value)` pairs. Equality comparison of the keys and values enforces reflexivity.

Order comparisons (`<`, `>`, `<=`, and `>=`) raise `TypeError`.

- Sets (instances of `set` or `frozenset`) can be compared within and across their types.

They define order comparison operators to mean subset and superset tests. Those relations do not define total orderings (for example, the two sets `{1, 2}` and `{2, 3}` are not equal, nor subsets of one another, nor supersets of one another). Accordingly, sets are not appropriate arguments for functions which depend on total ordering (for example, `min()`, `max()`, and `sorted()` produce undefined results given a list of sets as inputs).

Comparison of sets enforces reflexivity of its elements.

- Most other built-in types have no comparison methods implemented, so they inherit the default comparison behavior.

User-defined classes that customize their comparison behavior should follow some consistency rules, if possible:

- Equality comparison should be reflexive. In other words, identical objects should compare equal:

$x \text{ is } y \text{ implies } x == y$

- Comparison should be symmetric. In other words, the following expressions should have the same result:

$x == y \text{ and } y == x$

$x != y \text{ and } y != x$

$x < y \text{ and } y > x$

$x <= y \text{ and } y >= x$

- Comparison should be transitive. The following (non-exhaustive) examples illustrate that:

$x > y \text{ and } y > z \text{ implies } x > z$

$x < y \text{ and } y <= z \text{ implies } x < z$

- Inverse comparison should result in the boolean negation. In other words, the following expressions should have the same result:

$x == y \text{ and } \text{not } x != y$

$x < y \text{ and } \text{not } x >= y \text{ (for total ordering)}$

$x > y \text{ and } \text{not } x <= y \text{ (for total ordering)}$

The last two expressions apply to totally ordered collections (e.g. to sequences, but not to sets or mappings). See also the [`total\_ordering\(\)`](#) decorator.

- The [`hash\(\)`](#) result should be consistent with equality. Objects that are equal should either have the same hash value, or be marked as unhashable.

Python does not enforce these consistency rules. In fact, the not-a-number values are an example for not following these rules.

### 6.10.2. Membership test operations

The operators `in` and `not in` test for membership. `x in s` evaluates to `True` if `x` is a member of `s`, and `False` otherwise. `x not in s` returns the negation of `x in s`. All built-in sequences and set types support this as well as dictionary, for which `in` tests whether the dictionary has a given key. For container types such as list, tuple, set, frozenset, dict, or collections.deque, the expression `x in y` is equivalent to `any(x is e or x == e for e in y)`.

For the string and bytes types, `x in y` is `True` if and only if `x` is a substring of `y`. An equivalent test is `y.find(x) != -1`. Empty strings are always considered to be a substring of any other string, so `"" in "abc"` will return `True`.

For user-defined classes which define the `__contains__()` method, `x in y` returns `True` if `y.__contains__(x)` returns a true value, and `False` otherwise.

For user-defined classes which do not define `__contains__()` but do define `__iter__()`, `x in y` is `True` if some value `z`, for which the expression `x is z or x == z` is true, is produced while iterating over `y`. If an exception is raised during the iteration, it is as if `in` raised that exception.

Lastly, the old-style iteration protocol is tried: if a class defines `__getitem__()`, `x in y` is `True` if and only if there is a non-negative integer index `i` such that `x is y[i] or x == y[i]`, and no lower integer index raises the `IndexError` exception. (If any other exception is raised, it is as if `in` raised that exception).

The operator `not in` is defined to have the inverse truth value of `in`.

### 6.10.3. Identity comparisons

The operators `is` and `is not` test for an object's identity: `x is`

`y` is true if and only if `x` and `y` are the same object. An Object's identity is determined using the `id()` function. `x is not y` yields the inverse truth value. 4

## 6.11. Boolean operations

```
or_test    ::= and_test | or_test "or" and_test
and_test   ::= not_test  | and_test "and" not_test
not_test    ::= comparison | "not" not_test
```

In the context of Boolean operations, and also when expressions are used by control flow statements, the following values are interpreted as false: `False`, `None`, numeric zero of all types, and empty strings and containers (including strings, tuples, lists, dictionaries, sets and frozensets). All other values are interpreted as true. User-defined objects can customize their truth value by providing a `__bool__()` method.

The operator `not` yields `True` if its argument is false, `False` otherwise.

The expression `x and y` first evaluates `x`; if `x` is false, its value is returned; otherwise, `y` is evaluated and the resulting value is returned.

The expression `x or y` first evaluates `x`; if `x` is true, its value is returned; otherwise, `y` is evaluated and the resulting value is returned.

Note that neither `and` nor `or` restrict the value and type they return to `False` and `True`, but rather return the last evaluated argument. This is sometimes useful, e.g., if `s` is a string that should be replaced by a default value if it is empty, the expression `s or 'foo'` yields the desired value. Because `not` has to create a new value, it returns a boolean value regardless of the type of its argument (for example, `not 'foo'` produces `False` rather than `''`.)

## 6.12. Assignment expressions

**assignment\_expression** ::= [**identifier** "!="] **expression**

An assignment expression (sometimes also called a “named expression” or “walrus”) assigns an **expression** to an **identifier**, while also returning the value of the **expression**.

One common use case is when handling matched regular expressions:

```
if matching := pattern.search(data):  
    do_something(matching)
```

Or, when processing a file stream in chunks:

```
while chunk := file.read(9000):  
    process(chunk)
```

Assignment expressions must be surrounded by parentheses when used as sub-expressions in slicing, conditional, lambda, keyword-argument, and comprehension-if expressions and in `assert` and `with` statements. In all other places where they can be used, parentheses are not required, including in `if` and `while` statements.

*New in version 3.8:* See [PEP 572](https://peps.python.org/pep-0572/) [https://peps.python.org/pep-0572/] for more details about assignment expressions.

## 6.13. Conditional expressions

**conditional\_expression** ::= **or\_test** ["if" **or\_test** "else"  
**expression** ::= **conditional\_expression** | **lambda**

Conditional expressions (sometimes called a “ternary operator”) have the lowest priority of all Python operations.

The expression `x if C else y` first evaluates the condition, `C` rather than `x`. If `C` is true, `x` is evaluated and its value is returned; otherwise, `y` is evaluated and its value is returned.

See [PEP 308](https://peps.python.org/pep-0308/) [https://peps.python.org/pep-0308/] for more details about conditional expressions.

## 6.14. Lambdas

```
lambda_expr ::= "lambda" [parameter_list] ":" expression
```

Lambda expressions (sometimes called lambda forms) are used to create anonymous functions. The expression `lambda parameters: expression` yields a function object. The unnamed object behaves like a function object defined with:

```
def <lambda>(parameters):  
    return expression
```

See section [Function definitions](#) for the syntax of parameter lists. Note that functions created with lambda expressions cannot contain statements or annotations.

## 6.15. Expression lists

```
expression_list    ::= expression ("," expression) * ["  
starred_list      ::= starred_item ("," starred_item) *  
starred_expression ::= expression | (starred_item "," ) *  
starred_item      ::= assignment_expression | "*" or_e
```

Except when part of a list or set display, an expression list containing at least one comma yields a tuple. The length of the tuple is the number of expressions in the list. The expressions are evaluated from left to right.

An asterisk `*` denotes *iterable unpacking*. Its operand must be an [iterable](#). The iterable is expanded into a sequence of items, which are included in the new tuple, list, or set, at the site of the unpacking.

*New in version 3.5:* Iterable unpacking in expression lists, originally

proposed by [PEP 448](https://peps.python.org/pep-0448/) [https://peps.python.org/pep-0448/].

The trailing comma is required only to create a single tuple (a.k.a. a *singleton*); it is optional in all other cases. A single expression without a trailing comma doesn't create a tuple, but rather yields the value of that expression. (To create an empty tuple, use an empty pair of parentheses: `()`.)

## 6.16. Evaluation order

Python evaluates expressions from left to right. Notice that while evaluating an assignment, the right-hand side is evaluated before the left-hand side.

In the following lines, expressions will be evaluated in the arithmetic order of their suffixes:

```
expr1, expr2, expr3, expr4
(expr1, expr2, expr3, expr4)
{expr1: expr2, expr3: expr4}
expr1 + expr2 * (expr3 - expr4)
expr1(expr2, expr3, *expr4, **expr5)
expr3, expr4 = expr1, expr2
```

## 6.17. Operator precedence

The following table summarizes the operator precedence in Python, from highest precedence (most binding) to lowest precedence (least binding). Operators in the same box have the same precedence. Unless the syntax is explicitly given, operators are binary. Operators in the same box group left to right (except for exponentiation and conditional expressions, which group from right to left).

Note that comparisons, membership tests, and identity tests, all have the same precedence and have a left-to-right chaining feature as described in the [Comparisons](#) section.

Description
-------------

Binding or parenthesized expression, list display, dictionary
---

`display, setdisplay.], {key: value...},`

`{expressions...}`

Subscription, slicing, call, attribute reference

`x.attribute`

Await expression

Exponentiation **5**

Positive, negative, bitwise NOT

Multiplication, matrix multiplication, division, floor division, remainder **6**

Addition and subtraction

Shifts **>**

Bitwise AND

Bitwise XOR

Bitwise OR

Comparisons, including membership tests and identity tests

Boolean NOT

Boolean AND

Boolean OR

Conditional expression

Lambda expression

Assignment expression

## Footnotes

**1**

While  $\text{abs}(x\%y) < \text{abs}(y)$  is true mathematically, for floats it may not be true numerically due to roundoff. For example, and assuming a platform on which a Python float is an IEEE 754 double-precision number, in order that  $-1\text{e-}100 \% 1\text{e}100$  have the same sign as  $1\text{e}100$ , the computed result is  $-1\text{e-}100 + 1\text{e}100$ , which is numerically exactly equal to  $1\text{e}100$ . The function `math.fmod()` returns a result whose sign matches the sign of the first argument instead, and so returns  $-1\text{e-}100$  in this case. Which approach is more appropriate depends on the application.

**2**

If  $x$  is very close to an exact integer multiple of  $y$ , it's possible for  $x//y$  to be one larger than  $(x-x\%y)//y$  due to rounding.

In such cases, Python returns the latter result, in order to preserve that `divmod(x, y)[0] * y + x % y` be very close to `x`.

3

The Unicode standard distinguishes between *code points* (e.g. U+0041) and *abstract characters* (e.g. “LATIN CAPITAL LETTER A”). While most abstract characters in Unicode are only represented using one code point, there is a number of abstract characters that can in addition be represented using a sequence of more than one code point. For example, the abstract character “LATIN CAPITAL LETTER C WITH CEDILLA” can be represented as a single *precomposed character* at code position U+00C7, or as a sequence of a *base character* at code position U+0043 (LATIN CAPITAL LETTER C), followed by a *combining character* at code position U+0327 (COMBINING CEDILLA).

The comparison operators on strings compare at the level of Unicode code points. This may be counter-intuitive to humans. For example, `"\u00C7" == "\u0043\u0327"` is `False`, even though both strings represent the same abstract character “LATIN CAPITAL LETTER C WITH CEDILLA”.

To compare strings at the level of abstract characters (that is, in a way intuitive to humans), use `unicodedata.normalize()`.

4

Due to automatic garbage-collection, free lists, and the dynamic nature of descriptors, you may notice seemingly unusual behaviour in certain uses of the `is` operator, like those involving comparisons between instance methods, or constants. Check their documentation for more info.

5

The power operator `**` binds less tightly than an arithmetic or bitwise unary operator on its right, that is, `2**-1` is `0.5`.

6

The `%` operator is also used for string formatting; the same

precedence applies.

# 7. Simple statements

A simple statement is comprised within a single logical line. Several simple statements may occur on a single line separated by semicolons. The syntax for simple statements is:

```
simple_stmt ::= expression_stmt
              | assert_stmt
              | assignment_stmt
              | augmented_assignment_stmt
              | annotated_assignment_stmt
              | pass_stmt
              | del_stmt
              | return_stmt
              | yield_stmt
              | raise_stmt
              | break_stmt
              | continue_stmt
              | import_stmt
              | future_stmt
              | global_stmt
              | nonlocal_stmt
```

## 7.1. Expression statements

Expression statements are used (mostly interactively) to compute and write a value, or (usually) to call a procedure (a function that returns no meaningful result; in Python, procedures return the value `None`). Other uses of expression statements are allowed and occasionally useful. The syntax for an expression statement is:

```
expression_stmt ::= starred_expression
```

An expression statement evaluates the expression list (which may be a single expression).

In interactive mode, if the value is not `None`, it is converted to a string using the built-in `repr()` function and the resulting string is written to standard output on a line by itself (except if the result is `None`, so that procedure calls do not cause any output.)

## 7.2. Assignment statements

Assignment statements are used to (re)bind names to values and to modify attributes or items of mutable objects:

```
assignment_stmt ::= (target_list "=") + (starred_expression)
target_list      ::= target ("," target) * [" "]
target          ::= identifier
                  | "(" [target_list] ")"
                  | "[" [target_list] "]"
                  | attributeref
                  | subscription
                  | slicing
                  | "*" target
```

(See section [Primitives](#) for the syntax definitions for *attributeref*, *subscription*, and *slicing*.)

An assignment statement evaluates the expression list (remember that this can be a single expression or a comma-separated list, the latter yielding a tuple) and assigns the single resulting object to each of the target lists, from left to right.

Assignment is defined recursively depending on the form of the target (list). When a target is part of a mutable object (an attribute reference, subscription or slicing), the mutable object must ultimately perform the assignment and decide about its validity, and may raise an exception if the assignment is unacceptable. The rules observed by various types and the exceptions raised are given with the definition of the object types (see section [The standard type hierarchy](#)).

Assignment of an object to a target list, optionally enclosed in parentheses or square brackets, is recursively defined as follows.

- If the target list is a single target with no trailing comma, optionally in parentheses, the object is assigned to that target.
- Else:
  - If the target list contains one target prefixed with an asterisk, called a “starred” target: The object must be an iterable with at least as many items as there are targets in the target list, minus one. The first items of the iterable are assigned, from left to right, to the targets before the starred target. The final items of the iterable are assigned to the targets after the starred target. A list of the remaining items in the iterable is then assigned to the starred target (the list can be empty).
  - Else: The object must be an iterable with the same number of items as there are targets in the target list, and the items are assigned, from left to right, to the corresponding targets.

Assignment of an object to a single target is recursively defined as follows.

- If the target is an identifier (name):
  - If the name does not occur in a `global` or `nonlocal` statement in the current code block: the name is bound to the object in the current local namespace.
  - Otherwise: the name is bound to the object in the global namespace or the outer namespace determined by `nonlocal`, respectively.

The name is rebound if it was already bound. This may cause the reference count for the object previously bound to the name to reach zero, causing the object to be deallocated and its destructor (if it has one) to be called.

- If the target is an attribute reference: The primary expression in the reference is evaluated. It should yield an object with assignable attributes; if this is not the case, `TypeError` is raised. That object is then asked to assign the assigned object

to the given attribute; if it cannot perform the assignment, it raises an exception (usually but not necessarily `AttributeError`).

Note: If the object is a class instance and the attribute reference occurs on both sides of the assignment operator, the right-hand side expression, `a.x` can access either an instance attribute or (if no instance attribute exists) a class attribute. The left-hand side target `a.x` is always set as an instance attribute, creating it if necessary. Thus, the two occurrences of `a.x` do not necessarily refer to the same attribute: if the right-hand side expression refers to a class attribute, the left-hand side creates a new instance attribute as the target of the assignment:

```
class Cls:
    x = 3                # class variable
inst = Cls()
inst.x = inst.x + 1     # writes inst.x as 4 leaving
```

This description does not necessarily apply to descriptor attributes, such as properties created with `property()`.

- If the target is a subscription: The primary expression in the reference is evaluated. It should yield either a mutable sequence object (such as a list) or a mapping object (such as a dictionary). Next, the subscript expression is evaluated.

If the primary is a mutable sequence object (such as a list), the subscript must yield an integer. If it is negative, the sequence's length is added to it. The resulting value must be a nonnegative integer less than the sequence's length, and the sequence is asked to assign the assigned object to its item with that index. If the index is out of range, `IndexError` is raised (assignment to a subscripted sequence cannot add new items to a list).

If the primary is a mapping object (such as a dictionary), the subscript must have a type compatible with the mapping's key type, and the mapping is then asked to create a key/value pair which maps the subscript to the assigned object. This can

either replace an existing key/value pair with the same key value, or insert a new key/value pair (if no key with the same value existed).

For user-defined objects, the `__setitem__()` method is called with appropriate arguments.

- If the target is a slicing: The primary expression in the reference is evaluated. It should yield a mutable sequence object (such as a list). The assigned object should be a sequence object of the same type. Next, the lower and upper bound expressions are evaluated, insofar they are present; defaults are zero and the sequence's length. The bounds should evaluate to integers. If either bound is negative, the sequence's length is added to it. The resulting bounds are clipped to lie between zero and the sequence's length, inclusive. Finally, the sequence object is asked to replace the slice with the items of the assigned sequence. The length of the slice may be different from the length of the assigned sequence, thus changing the length of the target sequence, if the target sequence allows it.

**CPython implementation detail:** In the current implementation, the syntax for targets is taken to be the same as for expressions, and invalid syntax is rejected during the code generation phase, causing less detailed error messages.

Although the definition of assignment implies that overlaps between the left-hand side and the right-hand side are ‘simultaneous’ (for example `a, b = b, a` swaps two variables), overlaps *within* the collection of assigned-to variables occur left-to-right, sometimes resulting in confusion. For instance, the following program prints `[0, 2]`:

```
x = [0, 1]
i = 0
i, x[i] = 1, 2          # i is updated, then x[i] is updated
print(x)
```

**See also**

## PEP 3132 [https://peps.python.org/pep-3132/] - Extended Iterable Unpacking

The specification for the `*target` feature.

### 7.2.1. Augmented assignment statements

Augmented assignment is the combination, in a single statement, of a binary operation and an assignment statement:

```
augmented_assignment_stmt ::= augtarget augop (expression_list)
augtarget                  ::= identifier | attributeref
augop                      ::= "+" | "-" | "*" | "@" | ">>=" | "<<=" | "&=" |
```

(See section [Primitives](#) for the syntax definitions of the last three symbols.)

An augmented assignment evaluates the target (which, unlike normal assignment statements, cannot be an unpacking) and the expression list, performs the binary operation specific to the type of assignment on the two operands, and assigns the result to the original target. The target is only evaluated once.

An augmented assignment expression like `x += 1` can be rewritten as `x = x + 1` to achieve a similar, but not exactly equal effect. In the augmented version, `x` is only evaluated once. Also, when possible, the actual operation is performed *in-place*, meaning that rather than creating a new object and assigning that to the target, the old object is modified instead.

Unlike normal assignments, augmented assignments evaluate the left-hand side *before* evaluating the right-hand side. For example, `a[i] += f(x)` first looks-up `a[i]`, then it evaluates `f(x)` and performs the addition, and lastly, it writes the result back to `a[i]`.

With the exception of assigning to tuples and multiple targets in a single statement, the assignment done by augmented assignment statements is handled the same way as normal assignments. Similarly, with the exception of the possible *in-place* behavior, the

binary operation performed by augmented assignment is the same as the normal binary operations.

For targets which are attribute references, the same [caveat about class and instance attributes](#) applies as for regular assignments.

### 7.2.2. Annotated assignment statements

[Annotation](#) assignment is the combination, in a single statement, of a variable or attribute annotation and an optional assignment statement:

```
annotated_assignment_stmt ::= augtarget ":" expression  
                           [ "=" (starred_expression
```

The difference from normal [Assignment statements](#) is that only a single target is allowed.

For simple names as assignment targets, if in class or module scope, the annotations are evaluated and stored in a special class or module attribute `__annotations__` that is a dictionary mapping from variable names (mangled if private) to evaluated annotations. This attribute is writable and is automatically created at the start of class or module body execution, if annotations are found statically.

For expressions as assignment targets, the annotations are evaluated if in class or module scope, but not stored.

If a name is annotated in a function scope, then this name is local for that scope. Annotations are never evaluated and stored in function scopes.

If the right hand side is present, an annotated assignment performs the actual assignment before evaluating annotations (where applicable). If the right hand side is not present for an expression target, then the interpreter evaluates the target except for the last `__setitem__()` or `__setattr__()` call.

The proposal that added syntax for annotating the types of variables (including class variables and instance variables), instead of expressing them through comments.

## PEP 484 [<https://peps.python.org/pep-0484/>] - Type hints

The proposal that added the `typing` module to provide a standard syntax for type annotations that can be used in static analysis tools and IDEs.

*Changed in version 3.8:* Now annotated assignments allow the same expressions in the right hand side as regular assignments. Previously, some expressions (like un-parenthesized tuple expressions) caused a syntax error.

## 7.3. The `assert` statement

Assert statements are a convenient way to insert debugging assertions into a program:

```
assert_stmt ::= "assert" expression ["," expression]
```

The simple form, `assert expression`, is equivalent to

```
if __debug__:
    if not expression: raise AssertionError
```

The extended form, `assert expression1, expression2`, is equivalent to

```
if __debug__:
    if not expression1: raise AssertionError(expression2)
```

These equivalences assume that `__debug__` and `AssertionError` refer to the built-in variables with those names. In the current implementation, the built-in variable `__debug__` is `True` under normal circumstances, `False` when optimization is requested (command line option `-O`). The current code generator

emits no code for an assert statement when optimization is requested at compile time. Note that it is unnecessary to include the source code for the expression that failed in the error message; it will be displayed as part of the stack trace.

Assignments to `__debug__` are illegal. The value for the built-in variable is determined when the interpreter starts.

## 7.4. The `pass` statement

```
pass_stmt ::= "pass"
```

`pass` is a null operation — when it is executed, nothing happens. It is useful as a placeholder when a statement is required syntactically, but no code needs to be executed, for example:

```
def f(arg): pass      # a function that does nothing (yet)
```

```
class C: pass         # a class with no methods (yet)
```

## 7.5. The `del` statement

```
del_stmt ::= "del" target_list
```

Deletion is recursively defined very similar to the way assignment is defined. Rather than spelling it out in full details, here are some hints.

Deletion of a target list recursively deletes each target, from left to right.

Deletion of a name removes the binding of that name from the local or global namespace, depending on whether the name occurs in a `global` statement in the same code block. If the name is unbound, a `NameError` exception will be raised.

Deletion of attribute references, subscriptions and slicings is passed to the primary object involved; deletion of a slicing is in general

equivalent to assignment of an empty slice of the right type (but even this is determined by the sliced object).

*Changed in version 3.2:* Previously it was illegal to delete a name from the local namespace if it occurs as a free variable in a nested block.

## 7.6. The `return` statement

```
return_stmt ::= "return" [expression_list]
```

**return** may only occur syntactically nested in a function definition, not within a nested class definition.

If an expression list is present, it is evaluated, else `None` is substituted.

**return** leaves the current function call with the expression list (or `None`) as return value.

When **return** passes control out of a **try** statement with a **finally** clause, that **finally** clause is executed before really leaving the function.

In a generator function, the **return** statement indicates that the generator is done and will cause **StopIteration** to be raised. The returned value (if any) is used as an argument to construct **StopIteration** and becomes the **StopIteration.value** attribute.

In an asynchronous generator function, an empty **return** statement indicates that the asynchronous generator is done and will cause **StopAsyncIteration** to be raised. A non-empty **return** statement is a syntax error in an asynchronous generator function.

## 7.7. The `yield` statement

**yield\_stmt ::= yield\_expression**

A **yield** statement is semantically equivalent to a **yield expression**. The yield statement can be used to omit the parentheses that would otherwise be required in the equivalent yield expression statement. For example, the yield statements

```
yield <expr>
yield from <expr>
```

are equivalent to the yield expression statements

```
(yield <expr>)
(yield from <expr>)
```

Yield expressions and statements are only used when defining a **generator** function, and are only used in the body of the generator function. Using yield in a function definition is sufficient to cause that definition to create a generator function instead of a normal function.

For full details of **yield** semantics, refer to the [Yield expressions](#) section.

## 7.8. The **raise** statement

**raise\_stmt ::= "raise" [expression ["from" expression]]**

If no expressions are present, **raise** re-raises the exception that is currently being handled, which is also known as the *active exception*. If there isn't currently an active exception, a **RuntimeError** exception is raised indicating that this is an error.

Otherwise, **raise** evaluates the first expression as the exception object. It must be either a subclass or an instance of **BaseException**. If it is a class, the exception instance will be obtained when needed by instantiating the class with no arguments.

The *type* of the exception is the exception instance's class, the *value* is the instance itself.

A traceback object is normally created automatically when an exception is raised and attached to it as the `__traceback__` attribute, which is writable. You can create an exception and set your own traceback in one step using the `with_traceback()` exception method (which returns the same exception instance, with its traceback set to its argument), like so:

```
raise Exception("foo occurred").with_traceback(traceback)
```

The `from` clause is used for exception chaining: if given, the second *expression* must be another exception class or instance. If the second expression is an exception instance, it will be attached to the raised exception as the `__cause__` attribute (which is writable). If the expression is an exception class, the class will be instantiated and the resulting exception instance will be attached to the raised exception as the `__cause__` attribute. If the raised exception is not handled, both exceptions will be printed:

```
>>> try:
...     print(1 / 0)
... except Exception as exc:
...     raise RuntimeError("Something bad happened") from exc
...
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
ZeroDivisionError: division by zero
```

The above exception was the direct cause of the following exception:

```
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError: Something bad happened
```

A similar mechanism works implicitly if a new exception is raised when an exception is already being handled. An exception may be handled when an `except` or `finally` clause, or a `with` statement, is used. The previous exception is then attached as the new exception's `__context__` attribute:

```
>>> try:
```

```
...     print(1 / 0)
... except:
...     raise RuntimeError("Something bad happened")
...
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
ZeroDivisionError: division by zero
```

During handling of the above exception, another exception occurred

```
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError: Something bad happened
```

Exception chaining can be explicitly suppressed by specifying **None** in the `from` clause:

```
>>> try:
...     print(1 / 0)
... except:
...     raise RuntimeError("Something bad happened") from None
...
Traceback (most recent call last):
  File "<stdin>", line 4, in <module>
RuntimeError: Something bad happened
```

Additional information on exceptions can be found in section [Exceptions](#), and information about handling exceptions is in section [The try statement](#).

*Changed in version 3.3:* **None** is now permitted as `Y` in `raise X from Y`.

*New in version 3.3:* The `__suppress_context__` attribute to suppress automatic display of the exception context.

*Changed in version 3.11:* If the traceback of the active exception is modified in an **except** clause, a subsequent `raise` statement re-raises the exception with the modified traceback. Previously, the exception was re-raised with the traceback it had when it was

caught.

## 7.9. The `break` statement

```
break_stmt ::= "break"
```

`break` may only occur syntactically nested in a `for` or `while` loop, but not nested in a function or class definition within that loop.

It terminates the nearest enclosing loop, skipping the optional `else` clause if the loop has one.

If a `for` loop is terminated by `break`, the loop control target keeps its current value.

When `break` passes control out of a `try` statement with a `finally` clause, that `finally` clause is executed before really leaving the loop.

## 7.10. The `continue` statement

```
continue_stmt ::= "continue"
```

`continue` may only occur syntactically nested in a `for` or `while` loop, but not nested in a function or class definition within that loop. It continues with the next cycle of the nearest enclosing loop.

When `continue` passes control out of a `try` statement with a `finally` clause, that `finally` clause is executed before really starting the next loop cycle.

## 7.11. The `import` statement

```
import_stmt ::= "import" module ["as" identifier] ( | "from" relative_module "import" i
```

```

                                ("," identifier ["as" identifier]) *
                                | "from" relative_module "import" "
                                ("," identifier ["as" identifier]) *
                                | "from" relative_module "import" "
module ::= (identifier ".") * identifier
relative_module ::= "." * module | "." +

```

The basic import statement (no **from** clause) is executed in two steps:

1. find a module, loading and initializing it if necessary
2. define a name or names in the local namespace for the scope where the **import** statement occurs.

When the statement contains multiple clauses (separated by commas) the two steps are carried out separately for each clause, just as though the clauses had been separated out into individual import statements.

The details of the first step, finding and loading modules, are described in greater detail in the section on the [import system](#), which also describes the various types of packages and modules that can be imported, as well as all the hooks that can be used to customize the import system. Note that failures in this step may indicate either that the module could not be located, *or* that an error occurred while initializing the module, which includes execution of the module's code.

If the requested module is retrieved successfully, it will be made available in the local namespace in one of three ways:

- If the module name is followed by **as**, then the name following **as** is bound directly to the imported module.
- If no other name is specified, and the module being imported is a top level module, the module's name is bound in the local namespace as a reference to the imported module
- If the module being imported is *not* a top level module, then the name of the top level package that contains the module is bound in the local namespace as a reference to the top level package. The imported module must be accessed using its full qualified name rather than directly

The `from` form uses a slightly more complex process:

1. find the module specified in the `from` clause, loading and initializing it if necessary;
2. for each of the identifiers specified in the `import` clauses:
  1. check if the imported module has an attribute by that name
  2. if not, attempt to import a submodule with that name and then check the imported module again for that attribute
  3. if the attribute is not found, `ImportError` is raised.
  4. otherwise, a reference to that value is stored in the local namespace, using the name in the `as` clause if it is present, otherwise using the attribute name

Examples:

```
import foo                # foo imported and bound locally
import foo.bar.baz        # foo, foo.bar, and foo.bar.baz
import foo.bar.baz as fbb # foo, foo.bar, and foo.bar.baz
from foo.bar import baz    # foo, foo.bar, and foo.bar.baz
from foo import attr       # foo imported and foo.attr bound
```

If the list of identifiers is replaced by a star (`'*'`), all public names defined in the module are bound in the local namespace for the scope where the `import` statement occurs.

The *public names* defined by a module are determined by checking the module's namespace for a variable named `__all__`; if defined, it must be a sequence of strings which are names defined or imported by that module. The names given in `__all__` are all considered public and are required to exist. If `__all__` is not defined, the set of public names includes all names found in the module's namespace which do not begin with an underscore character (`'_'`). `__all__` should contain the entire public API. It is intended to avoid accidentally exporting items that are not part of the API (such as library modules which were imported and used within the module).

The wild card form of import — `from module import *` — is only allowed at the module level. Attempting to use it in class or

function definitions will raise a `SyntaxError`.

When specifying what module to import you do not have to specify the absolute name of the module. When a module or package is contained within another package it is possible to make a relative import within the same top package without having to mention the package name. By using leading dots in the specified module or package after `from` you can specify how high to traverse up the current package hierarchy without specifying exact names. One leading dot means the current package where the module making the import exists. Two dots means up one package level. Three dots is up two levels, etc. So if you execute `from . import mod` from a module in the `pkg` package then you will end up importing `pkg.mod`. If you execute `from ..subpkg2 import mod` from within `pkg.subpkg1` you will import `pkg.subpkg2.mod`. The specification for relative imports is contained in the [Package Relative Imports](#) section.

`importlib.import_module()` is provided to support applications that determine dynamically the modules to be loaded.

Raises an `auditing event` `import` with arguments `module`, `filename`, `sys.path`, `sys.meta_path`, `sys.path_hooks`.

### 7.11.1. Future statements

A *future statement* is a directive to the compiler that a particular module should be compiled using syntax or semantics that will be available in a specified future release of Python where the feature becomes standard.

The future statement is intended to ease migration to future versions of Python that introduce incompatible changes to the language. It allows use of the new features on a per-module basis before the release in which the feature becomes standard.

```
future_stmt ::= "from" "__future__" "import" feature ["(" "feature ["as" identifier])*  
| "from" "__future__" "import" "(" feat
```

```
        ("," feature ["as" identifier]) * [","]
feature ::= identifier
```

A future statement must appear near the top of the module. The only lines that can appear before a future statement are:

- the module docstring (if any),
- comments,
- blank lines, and
- other future statements.

The only feature that requires using the future statement is annotations (see [PEP 563](https://peps.python.org/pep-0563/) [https://peps.python.org/pep-0563/]).

All historical features enabled by the future statement are still recognized by Python 3. The list includes `absolute_import`, `division`, `generators`, `generator_stop`, `unicode_literals`, `print_function`, `nested_scopes` and `with_statement`. They are all redundant because they are always enabled, and only kept for backwards compatibility.

A future statement is recognized and treated specially at compile time: Changes to the semantics of core constructs are often implemented by generating different code. It may even be the case that a new feature introduces new incompatible syntax (such as a new reserved word), in which case the compiler may need to parse the module differently. Such decisions cannot be pushed off until runtime.

For any given release, the compiler knows which feature names have been defined, and raises a compile-time error if a future statement contains a feature not known to it.

The direct runtime semantics are the same as for any import statement: there is a standard module `__future__`, described later, and it will be imported in the usual way at the time the future statement is executed.

The interesting runtime semantics depend on the specific feature enabled by the future statement.

Note that there is nothing special about the statement:

```
import __future__ [as name]
```

That is not a future statement; it's an ordinary import statement with no special semantics or syntax restrictions.

Code compiled by calls to the built-in functions `exec()` and `compile()` that occur in a module `M` containing a future statement will, by default, use the new syntax or semantics associated with the future statement. This can be controlled by optional arguments to `compile()` — see the documentation of that function for details.

A future statement typed at an interactive interpreter prompt will take effect for the rest of the interpreter session. If an interpreter is started with the `-i` option, is passed a script name to execute, and the script includes a future statement, it will be in effect in the interactive session started after the script is executed.

The original proposal for the `__future__` mechanism.

## 7.12. The `global` statement

```
global_stmt ::= "global" identifier ("," identifier) *
```

The `global` statement is a declaration which holds for the entire current code block. It means that the listed identifiers are to be interpreted as globals. It would be impossible to assign to a global variable without `global`, although free variables may refer to globals without being declared global.

Names listed in a `global` statement must not be used in the same code block textually preceding that `global` statement.

Names listed in a `global` statement must not be defined as formal parameters, or as targets in `with` statements or `except` clauses, or in a `for` target list, `class` definition, function definition, `import` statement, or variable annotation.

**CPython implementation detail:** The current implementation does not enforce some of these restrictions, but programs should not abuse this freedom, as future implementations may enforce them or silently change the meaning of the program.

**Programmer's note:** `global` is a directive to the parser. It applies only to code parsed at the same time as the `global` statement. In particular, a `global` statement contained in a string or code object supplied to the built-in `exec()` function does not affect the code block *containing* the function call, and code contained in such a string is unaffected by `global` statements in the code containing the function call. The same applies to the `eval()` and `compile()` functions.

## 7.13. The `nonlocal` statement

```
nonlocal_stmt ::= "nonlocal" identifier ("," identifier
```

The `nonlocal` statement causes the listed identifiers to refer to previously bound variables in the nearest enclosing scope excluding globals. This is important because the default behavior for binding is to search the local namespace first. The statement allows encapsulated code to rebind variables outside of the local scope besides the global (module) scope.

Names listed in a `nonlocal` statement, unlike those listed in a `global` statement, must refer to pre-existing bindings in an enclosing scope (the scope in which a new binding should be created cannot be determined unambiguously).

Names listed in a `nonlocal` statement must not collide with pre-existing bindings in the local scope.

**See also**

## **PEP 3104** [<https://peps.python.org/pep-3104/>] - Access to Names in Outer Scopes

The specification for the `nonlocal` statement.

## 8. Compound statements

Compound statements contain (groups of) other statements; they affect or control the execution of those other statements in some way. In general, compound statements span multiple lines, although in simple incarnations a whole compound statement may be contained in one line.

The **if**, **while** and **for** statements implement traditional control flow constructs. **try** specifies exception handlers and/or cleanup code for a group of statements, while the **with** statement allows the execution of initialization and finalization code around a block of code. Function and class definitions are also syntactically compound statements.

A compound statement consists of one or more ‘clauses.’ A clause consists of a header and a ‘suite.’ The clause headers of a particular compound statement are all at the same indentation level. Each clause header begins with a uniquely identifying keyword and ends with a colon. A suite is a group of statements controlled by a clause. A suite can be one or more semicolon-separated simple statements on the same line as the header, following the header’s colon, or it can be one or more indented statements on subsequent lines. Only the latter form of a suite can contain nested compound statements; the following is illegal, mostly because it wouldn’t be clear to which **if** clause a following **else** clause would belong:

```
if test1: if test2: print(x)
```

Also note that the semicolon binds tighter than the colon in this context, so that in the following example, either all or none of the **print()** calls are executed:

```
if x < y < z: print(x); print(y); print(z)
```

Summarizing:

```

compound_stmt ::= if_stmt
                  | while_stmt
                  | for_stmt
                  | try_stmt
                  | with_stmt
                  | match_stmt
                  | funcdef
                  | classdef
                  | async_with_stmt
                  | async_for_stmt
                  | async_funcdef

suite          ::= stmt_list NEWLINE | NEWLINE INDENT stmt_list DEDENT
statement     ::= stmt_list NEWLINE | compound_stmt
stmt_list      ::= simple_stmt (";" simple_stmt) * [";"]

```

Note that statements always end in a `NEWLINE` possibly followed by a `DEDENT`. Also note that optional continuation clauses always begin with a keyword that cannot start a statement, thus there are no ambiguities (the ‘dangling `else`’ problem is solved in Python by requiring nested `if` statements to be indented).

The formatting of the grammar rules in the following sections places each clause on a separate line for clarity.

## 8.1. The `if` statement

The `if` statement is used for conditional execution:

```

if_stmt ::= "if" assignment_expression ":" suite
            ("elif" assignment_expression ":" suite) *
            ["else" ":" suite]

```

It selects exactly one of the suites by evaluating the expressions one by one until one is found to be true (see section [Boolean operations](#) for the definition of true and false); then that suite is executed (and no other part of the `if` statement is executed or evaluated). If all expressions are false, the suite of the `else` clause, if present, is

executed.

## 8.2. The **while** statement

The **while** statement is used for repeated execution as long as an expression is true:

```
while_stmt ::= "while" assignment_expression ":" suite
               ["else" ":" suite]
```

This repeatedly tests the expression and, if it is true, executes the first suite; if the expression is false (which may be the first time it is tested) the suite of the **else** clause, if present, is executed and the loop terminates.

A **break** statement executed in the first suite terminates the loop without executing the **else** clause's suite. A **continue** statement executed in the first suite skips the rest of the suite and goes back to testing the expression.

## 8.3. The **for** statement

The **for** statement is used to iterate over the elements of a sequence (such as a string, tuple or list) or other iterable object:

```
for_stmt ::= "for" target_list "in" starred_list ":" suite
               ["else" ":" suite]
```

The `starred_list` expression is evaluated once; it should yield an **iterable** object. An **iterator** is created for that iterable. The first item provided by the iterator is then assigned to the target list using the standard rules for assignments (see [Assignment statements](#)), and the suite is executed. This repeats for each item provided by the iterator. When the iterator is exhausted, the suite in the **else** clause, if present, is executed, and the loop terminates.

A **break** statement executed in the first suite terminates the loop without executing the **else** clause's suite. A **continue** statement

executed in the first suite skips the rest of the suite and continues with the next item, or with the **else** clause if there is no next item.

The for-loop makes assignments to the variables in the target list. This overwrites all previous assignments to those variables including those made in the suite of the for-loop:

```
for i in range(10):
    print(i)
    i = 5                                # this will not affect the for-loop
                                        # because i will be overwritten with
                                        # index in the range
```

Names in the target list are not deleted when the loop is finished, but if the sequence is empty, they will not have been assigned to at all by the loop. Hint: the built-in type `range()` represents immutable arithmetic sequences of integers. For instance, iterating `range(3)` successively yields 0, 1, and then 2.

*Changed in version 3.11:* Starred elements are now allowed in the expression list.

## 8.4. The **try** statement

The **try** statement specifies exception handlers and/or cleanup code for a group of statements:

```
try_stmt ::= try1_stmt | try2_stmt | try3_stmt
try1_stmt ::= "try" ":" suite
              ("except" [expression ["as" identifier]]
               ["else" ":" suite]
               ["finally" ":" suite])
try2_stmt ::= "try" ":" suite
              ("except" "*" expression ["as" identifier]
               ["else" ":" suite]
               ["finally" ":" suite])
try3_stmt ::= "try" ":" suite
              "finally" ":" suite
```

Additional information on exceptions can be found in section [Exceptions](#), and information on using the `raise` statement to generate exceptions may be found in section [The raise statement](#).

### 8.4.1. `except` clause

The `except` clause(s) specify one or more exception handlers. When no exception occurs in the `try` clause, no exception handler is executed. When an exception occurs in the `try` suite, a search for an exception handler is started. This search inspects the `except` clauses in turn until one is found that matches the exception. An expression-less `except` clause, if present, must be last; it matches any exception. For an `except` clause with an expression, that expression is evaluated, and the clause matches the exception if the resulting object is “compatible” with the exception. An object is compatible with an exception if the object is the class or a [non-virtual base class](#) of the exception object, or a tuple containing an item that is the class or a non-virtual base class of the exception object.

If no `except` clause matches the exception, the search for an exception handler continues in the surrounding code and on the invocation stack. [1](#)

If the evaluation of an expression in the header of an `except` clause raises an exception, the original search for a handler is canceled and a search starts for the new exception in the surrounding code and on the call stack (it is treated as if the entire `try` statement raised the exception).

When a matching `except` clause is found, the exception is assigned to the target specified after the `as` keyword in that `except` clause, if present, and the `except` clause’s suite is executed. All `except` clauses must have an executable block. When the end of this block is reached, execution continues normally after the entire `try` statement. (This means that if two nested handlers exist for the same exception, and the exception occurs in the `try` clause of the inner handler, the outer handler will not handle the exception.)

When an exception has been assigned using `as target`, it is

cleared at the end of the **except** clause. This is as if

```
except E as N:  
    foo
```

was translated to

```
except E as N:  
    try:  
        foo  
    finally:  
        del N
```

This means the exception must be assigned to a different name to be able to refer to it after the **except** clause. Exceptions are cleared because with the traceback attached to them, they form a reference cycle with the stack frame, keeping all locals in that frame alive until the next garbage collection occurs.

Before an **except** clause's suite is executed, the exception is stored in the **sys** module, where it can be accessed from within the body of the **except** clause by calling **sys.exception()**. When leaving an exception handler, the exception stored in the **sys** module is reset to its previous value:

```
>>> print(sys.exception())  
None  
>>> try:  
...     raise TypeError  
... except:  
...     print(repr(sys.exception()))  
...     try:  
...         raise ValueError  
...     except:  
...         print(repr(sys.exception()))  
...     print(repr(sys.exception()))  
...  
TypeError()  
ValueError()  
TypeError()
```

```
>>> print(sys.exception())
None
```

## 8.4.2. **except\*** clause

The **except\*** clause(s) are used for handling [ExceptionGroups](#). The exception type for matching is interpreted as in the case of [except](#), but in the case of exception groups we can have partial matches when the type matches some of the exceptions in the group. This means that multiple **except\*** clauses can execute, each handling part of the exception group. Each clause executes at most once and handles an exception group of all matching exceptions. Each exception in the group is handled by at most one **except\*** clause, the first that matches it.

```
>>> try:
...     raise ExceptionGroup("eg",
...                           [ValueError(1), TypeError(2), OSError(3), OS
... except* TypeError as e:
...     print(f'caught {type(e)} with nested {e.exceptions}')
... except* OSError as e:
...     print(f'caught {type(e)} with nested {e.exceptions}')
...
caught <class 'ExceptionGroup'> with nested (TypeError(2),
caught <class 'ExceptionGroup'> with nested (OSError(3),
+ Exception Group Traceback (most recent call last):
|   File "<stdin>", line 2, in <module>
|   ExceptionGroup: eg
+-+----- 1 -----
|   ValueError: 1
+-----
```

Any remaining exceptions that were not handled by any **except\*** clause are re-raised at the end, combined into an exception group along with all exceptions that were raised from within **except\*** clauses.

From version 3.11.4, when the entire [ExceptionGroup](#) is handled and only one exception is raised from an **except\*** clause, this exception is no longer wrapped to form a new [ExceptionGroup](#).

If the raised exception is not an exception group and its type matches one of the **except\*** clauses, it is caught and wrapped by an exception group with an empty message string.

```
>>> try:
...     raise BlockingIOError
... except* BlockingIOError as e:
...     print(repr(e))
...
ExceptionGroup('', (BlockingIOError()))
```

An **except\*** clause must have a matching type, and this type cannot be a subclass of **BaseExceptionGroup**. It is not possible to mix **except** and **except\*** in the same **try**. **break**, **continue** and **return** cannot appear in an **except\*** clause.

### 8.4.3. **else** clause

The optional **else** clause is executed if the control flow leaves the **try** suite, no exception was raised, and no **return**, **continue**, or **break** statement was executed. Exceptions in the **else** clause are not handled by the preceding **except** clauses.

### 8.4.4. **finally** clause

If **finally** is present, it specifies a ‘cleanup’ handler. The **try** clause is executed, including any **except** and **else** clauses. If an exception occurs in any of the clauses and is not handled, the exception is temporarily saved. The **finally** clause is executed. If there is a saved exception it is re-raised at the end of the **finally** clause. If the **finally** clause raises another exception, the saved exception is set as the context of the new exception. If the **finally** clause executes a **return**, **break** or **continue** statement, the saved exception is discarded:

```
>>> def f():
...     try:
...         1/0
...     finally:
...         return 42
```

```
...
>>> f()
42
```

The exception information is not available to the program during execution of the **finally** clause.

When a **return**, **break** or **continue** statement is executed in the **try** suite of a **try...finally** statement, the **finally** clause is also executed ‘on the way out.’

The return value of a function is determined by the last **return** statement executed. Since the **finally** clause always executes, a **return** statement executed in the **finally** clause will always be the last one executed:

```
>>> def foo():
...     try:
...         return 'try'
...     finally:
...         return 'finally'
...
>>> foo()
'finally'
```

*Changed in version 3.8:* Prior to Python 3.8, a **continue** statement was illegal in the **finally** clause due to a problem with the implementation.

## 8.5. The **with** statement

The **with** statement is used to wrap the execution of a block with methods defined by a context manager (see section [With Statement Context Managers](#)). This allows common **try...except...finally** usage patterns to be encapsulated for convenient reuse.

```
with_stmt          ::=  "with" ( "(" with_stmt_contents
with_stmt_contents ::=  with_item ( "," with_item ) *
with_item         ::=  expression [ "as" target ]
```

The execution of the `with` statement with one “item” proceeds as follows:

1. The context expression (the expression given in the `with_item`) is evaluated to obtain a context manager.
2. The context manager’s `__enter__()` is loaded for later use.
3. The context manager’s `__exit__()` is loaded for later use.
4. The context manager’s `__enter__()` method is invoked.
5. If a target was included in the `with` statement, the return value from `__enter__()` is assigned to it.

### Note

The `with` statement guarantees that if the `__enter__()` method returns without an error, then `__exit__()` will always be called. Thus, if an error occurs during the assignment to the target list, it will be treated the same as an error occurring within the suite would be. See step 7 below.

6. The suite is executed.
7. The context manager’s `__exit__()` method is invoked. If an exception caused the suite to be exited, its type, value, and traceback are passed as arguments to `__exit__()`. Otherwise, three `None` arguments are supplied.

If the suite was exited due to an exception, and the return value from the `__exit__()` method was false, the exception is reraised. If the return value was true, the exception is suppressed, and execution continues with the statement following the `with` statement.

If the suite was exited for any reason other than an exception, the return value from `__exit__()` is ignored, and execution proceeds at the normal location for the kind of exit that was

taken.

The following code:

```
with EXPRESSION as TARGET:
    SUITE
```

is semantically equivalent to:

```
manager = (EXPRESSION)
enter = type(manager).__enter__
exit = type(manager).__exit__
value = enter(manager)
hit_except = False

try:
    TARGET = value
    SUITE
except:
    hit_except = True
    if not exit(manager, *sys.exc_info()):
        raise
finally:
    if not hit_except:
        exit(manager, None, None, None)
```

With more than one item, the context managers are processed as if multiple **with** statements were nested:

```
with A() as a, B() as b:
    SUITE
```

is semantically equivalent to:

```
with A() as a:
    with B() as b:
        SUITE
```

You can also write multi-item context managers in multiple lines if the items are surrounded by parentheses. For example:

```
with (
    A() as a,
    B() as b,
):
    SUITE
```

*Changed in version 3.1:* Support for multiple context expressions.

*Changed in version 3.10:* Support for using grouping parentheses to break the statement in multiple lines.

### See also

**PEP 343** [<https://peps.python.org/pep-0343/>] - The “with” statement

The specification, background, and examples for the Python **with** statement.

## 8.6. The `match` statement

*New in version 3.10.*

The `match` statement is used for pattern matching. Syntax:

```
match_stmt ::= 'match' subject_expr ":" NEWLINE INDENT
subject_expr ::= star_named_expression ", " star_named_e
                | named_expression
case_block ::= 'case' patterns [guard] ":" block
```

### Note

This section uses single quotes to denote **soft keywords**.

Pattern matching takes a pattern as input (following `case`) and a subject value (following `match`). The pattern (which may contain subpatterns) is matched against the subject value. The outcomes are:

- A match success or failure (also termed a pattern success or failure).
- Possible binding of matched values to a name. The prerequisites for this are further discussed below.

The `match` and `case` keywords are [soft keywords](#).

- [PEP 634](https://peps.python.org/pep-0634/) [https://peps.python.org/pep-0634/] – Structural Pattern Matching: Specification
- [PEP 636](https://peps.python.org/pep-0636/) [https://peps.python.org/pep-0636/] – Structural Pattern Matching: Tutorial

### 8.6.1. Overview

Here's an overview of the logical flow of a match statement:

1. The subject expression `subject_expr` is evaluated and a resulting subject value obtained. If the subject expression contains a comma, a tuple is constructed using [the standard rules](#).
2. Each pattern in a `case_block` is attempted to match with the subject value. The specific rules for success or failure are described below. The match attempt can also bind some or all of the standalone names within the pattern. The precise pattern binding rules vary per pattern type and are specified below. **Name bindings made during a successful pattern match outlive the executed block and can be used after the match statement.**

#### Note

During failed pattern matches, some subpatterns may succeed. Do not rely on bindings being made for a failed match. Conversely, do not rely on variables remaining unchanged after a failed match.

The exact behavior is dependent on implementation and may vary. This is an intentional decision made to allow different implementations to add optimizations.

3. If the pattern succeeds, the corresponding guard (if present) is evaluated. In this case all name bindings are guaranteed to have happened.

- If the guard evaluates as true or is missing, the `block` inside `case_block` is executed.
- Otherwise, the next `case_block` is attempted as described above.
- If there are no further case blocks, the match statement is completed.

## Note

Users should generally never rely on a pattern being evaluated. Depending on implementation, the interpreter may cache values or use other optimizations which skip repeated evaluations.

A sample match statement:

```
>>> flag = False
>>> match (100, 200):
...     case (100, 300): # Mismatch: 200 != 300
...         print('Case 1')
...     case (100, 200) if flag: # Successful match, but
...         print('Case 2')
...     case (100, y): # Matches and binds y to 200
...         print(f'Case 3, y: {y}')
...     case _: # Pattern not attempted
...         print('Case 4, I match anything!')
...
Case 3, y: 200
```

In this case, `if flag` is a guard. Read more about that in the next section.

## 8.6.2. Guards

**guard** ::= `"if" named_expression`

A `guard` (which is part of the `case`) must succeed for code inside the `case` block to execute. It takes the form: `if` followed by an expression.

The logical flow of a `case` block with a `guard` follows:

1. Check that the pattern in the `case` block succeeded. If the pattern failed, the `guard` is not evaluated and the next `case` block is checked.
2. If the pattern succeeded, evaluate the `guard`.
  - If the `guard` condition evaluates as true, the case block is selected.
  - If the `guard` condition evaluates as false, the case block is not selected.
  - If the `guard` raises an exception during evaluation, the exception bubbles up.

Guards are allowed to have side effects as they are expressions. Guard evaluation must proceed from the first to the last case block, one at a time, skipping case blocks whose pattern(s) don't all succeed. (I.e., guard evaluation must happen in order.) Guard evaluation must stop once a case block is selected.

## 8.6.3. Irrefutable Case Blocks

An irrefutable case block is a match-all case block. A match statement may have at most one irrefutable case block, and it must be last.

A case block is considered irrefutable if it has no guard and its pattern is irrefutable. A pattern is considered irrefutable if we can prove from its syntax alone that it will always succeed. Only the

following patterns are irrefutable:

- [AS Patterns](#) whose left-hand side is irrefutable
- [OR Patterns](#) containing at least one irrefutable pattern
- [Capture Patterns](#)
- [Wildcard Patterns](#)
- parenthesized irrefutable patterns

## 8.6.4. Patterns

### Note

This section uses grammar notations beyond standard EBNF:

- the notation `SEP . RULE+` is shorthand for `RULE (SEP RULE) *`
- the notation `!RULE` is shorthand for a negative lookahead assertion

The top-level syntax for `patterns` is:

```
patterns      ::= open_sequence_pattern | pattern
pattern       ::= as_pattern | or_pattern
closed_pattern ::=
    | literal_pattern
    | capture_pattern
    | wildcard_pattern
    | value_pattern
    | group_pattern
    | sequence_pattern
    | mapping_pattern
    | class_pattern
```

The descriptions below will include a description “in simple terms” of what a pattern does for illustration purposes (credits to Raymond Hettinger for a document that inspired most of the descriptions). Note that these descriptions are purely for illustration purposes and **may not** reflect the underlying implementation. Furthermore, they do not cover all valid forms.

### 8.6.4.1. OR Patterns

An OR pattern is two or more patterns separated by vertical bars `|`. Syntax:

```
or_pattern ::= " | ".closed_pattern+
```

Only the final subpattern may be [irrefutable](#), and each subpattern must bind the same set of names to avoid ambiguity.

An OR pattern matches each of its subpatterns in turn to the subject value, until one succeeds. The OR pattern is then considered successful. Otherwise, if none of the subpatterns succeed, the OR pattern fails.

In simple terms, `P1 | P2 | ...` will try to match `P1`, if it fails it will try to match `P2`, succeeding immediately if any succeeds, failing otherwise.

### 8.6.4.2. AS Patterns

An AS pattern matches an OR pattern on the left of the `as` keyword against a subject. Syntax:

```
as_pattern ::= or_pattern "as" capture_pattern
```

If the OR pattern fails, the AS pattern fails. Otherwise, the AS pattern binds the subject to the name on the right of the `as` keyword and succeeds. `capture_pattern` cannot be a `_`.

In simple terms `P as NAME` will match with `P`, and on success it will set `NAME = <subject>`.

### 8.6.4.3. Literal Patterns

A literal pattern corresponds to most [literals](#) in Python. Syntax:

```

literal_pattern ::= signed_number
                    | signed_number "+" NUMBER
                    | signed_number "-" NUMBER
                    | strings
                    | "None"
                    | "True"
                    | "False"
                    | signed_number: NUMBER | "-" NUMBER

```

The rule `strings` and the token `NUMBER` are defined in the [standard Python grammar](#). Triple-quoted strings are supported. Raw strings and byte strings are supported. [Formatted string literals](#) are not supported.

The forms `signed_number '+' NUMBER` and `signed_number '-' NUMBER` are for expressing [complex numbers](#); they require a real number on the left and an imaginary number on the right. E.g. `3 + 4j`.

In simple terms, `LITERAL` will succeed only if `<subject> == LITERAL`. For the singletons `None`, `True` and `False`, the [is](#) operator is used.

#### 8.6.4.4. Capture Patterns

A capture pattern binds the subject value to a name. Syntax:

```

capture_pattern ::= !'_' NAME

```

A single underscore `_` is not a capture pattern (this is what `! '_'` expresses). It is instead treated as a [wildcard pattern](#).

In a given pattern, a given name can only be bound once. E.g. `case x, x: ...` is invalid while `case [x] | x: ...` is allowed.

Capture patterns always succeed. The binding follows scoping rules established by the assignment expression operator in [PEP 572](#) [<https://peps.python.org/pep-0572/>]; the name becomes a local variable in

the closest containing function scope unless there's an applicable `global` or `nonlocal` statement.

In simple terms `NAME` will always succeed and it will set `NAME = <subject>`.

#### 8.6.4.5. Wildcard Patterns

A wildcard pattern always succeeds (matches anything) and binds no name. Syntax:

```
wildcard_pattern ::=  '_'
```

`_` is a `soft keyword` within any pattern, but only within patterns. It is an identifier, as usual, even within `match` subject expressions, guards, and `case` blocks.

In simple terms, `_` will always succeed.

#### 8.6.4.6. Value Patterns

A value pattern represents a named value in Python. Syntax:

```
value_pattern ::=  attr  
attr           ::=  name_or_attr "." NAME  
name_or_attr  ::=  attr | NAME
```

The dotted name in the pattern is looked up using standard Python `name resolution rules`. The pattern succeeds if the value found compares equal to the subject value (using the `==` equality operator).

In simple terms `NAME1.NAME2` will succeed only if `<subject> == NAME1.NAME2`

#### Note

If the same value occurs multiple times in the same match

statement, the interpreter may cache the first value found and reuse it rather than repeat the same lookup. This cache is strictly tied to a given execution of a given match statement.

#### 8.6.4.7. Group Patterns

A group pattern allows users to add parentheses around patterns to emphasize the intended grouping. Otherwise, it has no additional syntax. Syntax:

```
group_pattern ::= " (" pattern ") "
```

In simple terms  $(P)$  has the same effect as  $P$ .

#### 8.6.4.8. Sequence Patterns

A sequence pattern contains several subpatterns to be matched against sequence elements. The syntax is similar to the unpacking of a list or tuple.

```
sequence_pattern      ::= " [" [maybe_sequence_pattern]
                             | " (" [open_sequence_pattern]
open_sequence_pattern ::= maybe_star_pattern ", " [maybe
maybe_sequence_pattern ::= ", ".maybe_star_pattern+ ", "?
maybe_star_pattern    ::= star_pattern | pattern
star_pattern           ::= "*" (capture_pattern | wildcard)
```

There is no difference if parentheses or square brackets are used for sequence patterns (i.e.  $(...)$  vs  $[...]$ ).

#### Note

A single pattern enclosed in parentheses without a trailing comma (e.g.  $(3 \mid 4)$ ) is a **group pattern**. While a single pattern enclosed in square brackets (e.g.  $[3 \mid 4]$ ) is still a sequence pattern.

At most one star subpattern may be in a sequence pattern. The star subpattern may occur in any position. If no star subpattern is present, the sequence pattern is a fixed-length sequence pattern; otherwise it is a variable-length sequence pattern.

The following is the logical flow for matching a sequence pattern against a subject value:

1. If the subject value is not a sequence [2](#), the sequence pattern fails.
2. If the subject value is an instance of `str`, `bytes` or `bytearray` the sequence pattern fails.
3. The subsequent steps depend on whether the sequence pattern is fixed or variable-length.

If the sequence pattern is fixed-length:

1. If the length of the subject sequence is not equal to the number of subpatterns, the sequence pattern fails
2. Subpatterns in the sequence pattern are matched to their corresponding items in the subject sequence from left to right. Matching stops as soon as a subpattern fails. If all subpatterns succeed in matching their corresponding item, the sequence pattern succeeds.

Otherwise, if the sequence pattern is variable-length:

1. If the length of the subject sequence is less than the number of non-star subpatterns, the sequence pattern fails.
2. The leading non-star subpatterns are matched to their corresponding items as for fixed-length sequences.
3. If the previous step succeeds, the star subpattern matches a list formed of the remaining subject items, excluding the remaining items corresponding to non-star subpatterns following the star subpattern.
4. Remaining non-star subpatterns are matched to their corresponding subject items, as for a fixed-length sequence.

## Note

The length of the subject sequence is obtained via `len()` (i.e. via the `__len__()` protocol). This length may be cached by the interpreter in a similar manner as [value patterns](#).

In simple terms `[P1, P2, P3, ... , P<N>]` matches only if all the following happens:

- check `<subject>` is a sequence
- `len(subject) == <N>`
- `P1` matches `<subject>[0]` (note that this match can also bind names)
- `P2` matches `<subject>[1]` (note that this match can also bind names)
- ... and so on for the corresponding pattern/element.

### 8.6.4.9. Mapping Patterns

A mapping pattern contains one or more key-value patterns. The syntax is similar to the construction of a dictionary. Syntax:

```
mapping_pattern      ::=  "{" [items_pattern] "}"
items_pattern        ::=  ", ".key_value_pattern+ ", "?
key_value_pattern    ::=  (literal_pattern | value_pattern
                          | double_star_pattern
double_star_pattern  ::=  "***" capture_pattern
```

At most one double star pattern may be in a mapping pattern. The double star pattern must be the last subpattern in the mapping pattern.

Duplicate keys in mapping patterns are disallowed. Duplicate literal keys will raise a [SyntaxError](#). Two keys that otherwise have the same value will raise a [ValueError](#) at runtime.

The following is the logical flow for matching a mapping pattern

against a subject value:

1. If the subject value is not a mapping [3](#), the mapping pattern fails.
2. If every key given in the mapping pattern is present in the subject mapping, and the pattern for each key matches the corresponding item of the subject mapping, the mapping pattern succeeds.
3. If duplicate keys are detected in the mapping pattern, the pattern is considered invalid. A [SyntaxError](#) is raised for duplicate literal values; or a [ValueError](#) for named keys of the same value.

## Note

Key-value pairs are matched using the two-argument form of the mapping subject's `get()` method. Matched key-value pairs must already be present in the mapping, and not created on-the-fly via `__missing__()` or `__getitem__()`.

In simple terms `{KEY1: P1, KEY2: P2, ... }` matches only if all the following happens:

- check `<subject>` is a mapping
- `KEY1` in `<subject>`
- `P1` matches `<subject>[KEY1]`
- ... and so on for the corresponding KEY/pattern pair.

### 8.6.4.10. Class Patterns

A class pattern represents a class and its positional and keyword arguments (if any). Syntax:

```
class_pattern      ::= name_or_attr "(" [pattern_argument
pattern_arguments  ::= positional_patterns ["," keyword_patterns
                        | keyword_patterns
positional_patterns ::= "," ".pattern+
keyword_patterns    ::= "," ".keyword_pattern+
```

**keyword\_pattern** ::= NAME "=" **pattern**

The same keyword should not be repeated in class patterns.

The following is the logical flow for matching a class pattern against a subject value:

1. If `name_or_attr` is not an instance of the builtin **type**, raise **TypeError**.
2. If the subject value is not an instance of `name_or_attr` (tested via **isinstance()**), the class pattern fails.
3. If no pattern arguments are present, the pattern succeeds. Otherwise, the subsequent steps depend on whether keyword or positional argument patterns are present.

For a number of built-in types (specified below), a single positional subpattern is accepted which will match the entire subject; for these types keyword patterns also work as for other types.

If only keyword patterns are present, they are processed as follows, one by one:

- I. The keyword is looked up as an attribute on the subject.
    - If this raises an exception other than **AttributeError**, the exception bubbles up.
    - If this raises **AttributeError**, the class pattern has failed.
    - Else, the subpattern associated with the keyword pattern is matched against the subject's attribute value. If this fails, the class pattern fails; if this succeeds, the match proceeds to the next keyword.
  - II. If all keyword patterns succeed, the class pattern succeeds.
- If any positional patterns are present, they are converted to

keyword patterns using the `__match_args__` attribute on the class `name_or_attr` before matching:

I. The equivalent of `getattr(cls, "__match_args__", ())` is called.

- If this raises an exception, the exception bubbles up.
- If the returned value is not a tuple, the conversion fails and `TypeError` is raised.
- If there are more positional patterns than `len(cls.__match_args__)`, `TypeError` is raised.
- Otherwise, positional pattern `i` is converted to a keyword pattern using `__match_args__[i]` as the keyword. `__match_args__[i]` must be a string; if not `TypeError` is raised.
- If there are duplicate keywords, `TypeError` is raised.

### See also

[Customizing positional arguments in class pattern matching](#)

II. Once all positional patterns have been converted to keyword patterns,  
the match proceeds as if there were only keyword patterns.

For the following built-in types the handling of positional subpatterns is different:

- `bool`
- `bytearray`
- `bytes`
- `dict`

- `float`
- `frozenset`
- `int`
- `list`
- `set`
- `str`
- `tuple`

These classes accept a single positional argument, and the pattern there is matched against the whole object rather than an attribute. For example `int(0|1)` matches the value `0`, but not the value `0.0`.

In simple terms `CLS(P1, attr=P2)` matches only if the following happens:

- `isinstance(<subject>, CLS)`
- `convert P1 to a keyword pattern using`  
`CLS.__match_args__`
- For each keyword argument `attr=P2`:
  - `hasattr(<subject>, "attr")`
  - `P2 matches <subject>.attr`
- ... and so on for the corresponding keyword argument/pattern pair.

## 8.7. Function definitions

A function definition defines a user-defined function object (see section [The standard type hierarchy](#)):

<b>funcdef</b>	<b>::=</b>	<b>[</b> <a href="#">decorators</a> <b>]</b> <b>"def"</b> <a href="#">funcname</a> <b>[</b> <b>"-&gt;"</b> <a href="#">expression</a> <b>]</b> <b>":"</b> <a href="#">suite</a>
<b>decorators</b>	<b>::=</b>	<a href="#">decorator</a> <b>+</b>
<b>decorator</b>	<b>::=</b>	<b>"@"</b> <a href="#">assignment_expression</a>
<b>parameter_list</b>	<b>::=</b>	<a href="#">defparameter</a> <b>(</b> <b>"</b> <a href="#">defparameter</a> <b> </b> <a href="#">parameter_list_no_posonly</a> <b>)</b>
<b>parameter_list_no_posonly</b>	<b>::=</b>	<a href="#">defparameter</a> <b>(</b> <b>"</b> <a href="#">defparameter</a> <b> </b> <a href="#">parameter_list_starargs</a> <b>)</b>
<b>parameter_list_starargs</b>	<b>::=</b>	<b>"*" [</b> <a href="#">parameter</a> <b>]</b> <b>(</b> <b>"</b> <a href="#">defparameter</a> <b> </b> <b>"**" parameter [</b> <b>"</b> <b>]</b> <b>)</b>
<b>parameter</b>	<b>::=</b>	<a href="#">identifier</a> <b>[</b> <b>":"</b> <a href="#">expression</a> <b>]</b>
<b>defparameter</b>	<b>::=</b>	<a href="#">parameter</a> <b>[</b> <b>"="</b> <a href="#">expression</a> <b>]</b>
<b>funcname</b>	<b>::=</b>	<a href="#">identifier</a>

A function definition is an executable statement. Its execution binds the function name in the current local namespace to a function object (a wrapper around the executable code for the function). This function object contains a reference to the current global namespace as the global namespace to be used when the function is called.

The function definition does not execute the function body; this gets executed only when the function is called. 4

A function definition may be wrapped by one or more [decorator](#) expressions. Decorator expressions are evaluated when the function is defined, in the scope that contains the function definition. The result must be a callable, which is invoked with the function object as the only argument. The returned value is bound to the function name instead of the function object. Multiple decorators are applied in nested fashion. For example, the following code

```
@f1(arg)
@f2
def func(): pass
```

is roughly equivalent to

```
def func(): pass
```

```
func = f1(arg)(f2(func))
```

except that the original function is not temporarily bound to the name `func`.

*Changed in version 3.9:* Functions may be decorated with any valid [assignment\\_expression](#). Previously, the grammar was much more restrictive; see [PEP 614](#) [<https://peps.python.org/pep-0614/>] for details.

When one or more [parameters](#) have the form *parameter = expression*, the function is said to have “default parameter values.” For a parameter with a default value, the corresponding [argument](#) may be omitted from a call, in which case the parameter’s default value is substituted. If a parameter has a default value, all following parameters up until the “\*” must also have a default value — this is a syntactic restriction that is not expressed by the grammar.

**Default parameter values are evaluated from left to right when the function definition is executed.** This means that the expression is evaluated once, when the function is defined, and that the same “pre-computed” value is used for each call. This is especially important to understand when a default parameter value is a mutable object, such as a list or a dictionary: if the function modifies the object (e.g. by appending an item to a list), the default parameter value is in effect modified. This is generally not what was intended. A way around this is to use `None` as the default, and explicitly test for it in the body of the function, e.g.:

```
def whats_on_the_telly(penguin=None):
    if penguin is None:
        penguin = []
    penguin.append("property of the zoo")
    return penguin
```

Function call semantics are described in more detail in section [Calls](#). A function call always assigns values to all parameters mentioned in the parameter list, either from positional arguments, from keyword arguments, or from default values. If the form “\**identifier*” is present, it is initialized to a tuple receiving any excess positional parameters, defaulting to the empty tuple. If the form

“`**identifier`” is present, it is initialized to a new ordered mapping receiving any excess keyword arguments, defaulting to a new empty mapping of the same type. Parameters after “`*`” or “`**identifier`” are keyword-only parameters and may only be passed by keyword arguments. Parameters before “`/`” are positional-only parameters and may only be passed by positional arguments.

*Changed in version 3.8:* The `/` function parameter syntax may be used to indicate positional-only parameters. See [PEP 570](https://peps.python.org/pep-0570/) [https://peps.python.org/pep-0570/] for details.

Parameters may have an [annotation](#) of the form “`: expression`” following the parameter name. Any parameter may have an annotation, even those of the form `*identifier` or `**identifier`. Functions may have “return” annotation of the form “`-> expression`” after the parameter list. These annotations can be any valid Python expression. The presence of annotations does not change the semantics of a function. The annotation values are available as values of a dictionary keyed by the parameters’ names in the `__annotations__` attribute of the function object. If the `annotations` import from [\\_\\_future\\_\\_](#) is used, annotations are preserved as strings at runtime which enables postponed evaluation. Otherwise, they are evaluated when the function definition is executed. In this case annotations may be evaluated in a different order than they appear in the source code.

It is also possible to create anonymous functions (functions not bound to a name), for immediate use in expressions. This uses lambda expressions, described in section [Lambdas](#). Note that the lambda expression is merely a shorthand for a simplified function definition; a function defined in a “`def`” statement can be passed around or assigned to another name just like a function defined by a lambda expression. The “`def`” form is actually more powerful since it allows the execution of multiple statements and annotations.

**Programmer’s note:** Functions are first-class objects. A “`def`” statement executed inside a function definition defines a local function that can be returned or passed around. Free variables used in the nested function can access the local variables of the function

containing the def. See section [Naming and binding](#) for details.

Support for forward references within annotations by preserving annotations in a string form at runtime instead of eager evaluation.

## 8.8. Class definitions

A class definition defines a class object (see section [The standard type hierarchy](#)):

```
classdef      ::=  [decorators] "class" classname [inheritance]  
inheritance ::=  "(" [argument_list] ")"  
classname   ::=  identifier
```

A class definition is an executable statement. The inheritance list usually gives a list of base classes (see [Metaclasses](#) for more advanced uses), so each item in the list should evaluate to a class object which allows subclassing. Classes without an inheritance list inherit, by default, from the base class [object](#); hence,

```
class Foo:
    pass
```

is equivalent to

```
class Foo(object):
    pass
```

The class's suite is then executed in a new execution frame (see [Naming and binding](#)), using a newly created local namespace and the original global namespace. (Usually, the suite contains mostly function definitions.) When the class's suite finishes execution, its execution frame is discarded but its local namespace is saved. <sup>5</sup> A class object is then created using the inheritance list for the base classes and the saved local namespace for the attribute dictionary. The class name is bound to this class object in the original local namespace.

The order in which attributes are defined in the class body is preserved in the new class's `__dict__`. Note that this is reliable only right after the class is created and only for classes that were defined using the definition syntax.

Class creation can be customized heavily using [metaclasses](#).

Classes can also be decorated: just like when decorating functions,

```
@f1(arg)
@f2
class Foo: pass
```

is roughly equivalent to

```
class Foo: pass
Foo = f1(arg)(f2(Foo))
```

The evaluation rules for the decorator expressions are the same as for function decorators. The result is then bound to the class name.

*Changed in version 3.9:* Classes may be decorated with any valid [assignment\\_expression](#). Previously, the grammar was much

more restrictive; see [PEP 614](https://peps.python.org/pep-0614/) [https://peps.python.org/pep-0614/] for details.

**Programmer’s note:** Variables defined in the class definition are class attributes; they are shared by instances. Instance attributes can be set in a method with `self.name = value`. Both class and instance attributes are accessible through the notation “`self.name`”, and an instance attribute hides a class attribute with the same name when accessed in this way. Class attributes can be used as defaults for instance attributes, but using mutable values there can lead to unexpected results. [Descriptors](#) can be used to create instance variables with different implementation details.

The proposal that added class decorators. Function and method decorators were introduced in [PEP 318](https://peps.python.org/pep-0318/) [https://peps.python.org/pep-0318/].

## 8.9. Coroutines

*New in version 3.5.*

### 8.9.1. Coroutine function definition

```
async_funcdef ::= [decorators] "async" "def" funcname "  
                    ["->" expression] ":" suite
```

Execution of Python coroutines can be suspended and resumed at many points (see [coroutine](#)). `await` expressions, `async for` and `async with` can only be used in the body of a coroutine function.

Functions defined with `async def` syntax are always coroutine functions, even if they do not contain `await` or `async` keywords.

It is a **SyntaxError** to use a `yield` from expression inside the body of a coroutine function.

An example of a coroutine function:

```
async def func(param1, param2):
    do_stuff()
    await some_coroutine()
```

*Changed in version 3.7:* `await` and `async` are now keywords; previously they were only treated as such inside the body of a coroutine function.

### 8.9.2. The `async for` statement

**`async_for_stmt`** ::= `"async"` **`for_stmt`**

An **asynchronous iterable** provides an `__aiter__` method that directly returns an **asynchronous iterator**, which can call asynchronous code in its `__anext__` method.

The `async for` statement allows convenient iteration over asynchronous iterables.

The following code:

```
async for TARGET in ITER:
    SUITE
else:
    SUITE2
```

Is semantically equivalent to:

```
iter = (ITER)
iter = type(iter).__aiter__(iter)
running = True
```

```

while running:
    try:
        TARGET = await type(iter).__anext__(iter)
    except StopAsyncIteration:
        running = False
    else:
        SUITE
else:
    SUITE2

```

See also `__aiter__()` and `__anext__()` for details.

It is a **SyntaxError** to use an `async` for statement outside the body of a coroutine function.

### 8.9.3. The `async with` statement

**`async_with_stmt`** ::= "async" **`with_stmt`**

An **asynchronous context manager** is a **context manager** that is able to suspend execution in its *enter* and *exit* methods.

The following code:

```

async with EXPRESSION as TARGET:
    SUITE

```

is semantically equivalent to:

```

manager = (EXPRESSION)
aenter = type(manager).__aenter__
aexit = type(manager).__aexit__
value = await aenter(manager)
hit_except = False

try:
    TARGET = value
    SUITE
except:

```

```

hit_except = True
if not await aexit(manager, *sys.exc_info()):
    raise
finally:
    if not hit_except:
        await aexit(manager, None, None, None)

```

See also `__aenter__()` and `__aexit__()` for details.

It is a **SyntaxError** to use an `async` with statement outside the body of a coroutine function.

## See also

**PEP 492** [<https://peps.python.org/pep-0492/>] - **Coroutines with `async` and `await` syntax**

The proposal that made coroutines a proper standalone concept in Python, and added supporting syntax.

## Footnotes

1

The exception is propagated to the invocation stack unless there is a **finally** clause which happens to raise another exception. That new exception causes the old one to be lost.

2

In pattern matching, a sequence is defined as one of the following:

- a class that inherits from `collections.abc.Sequence`
- a Python class that has been registered as `collections.abc.Sequence`
- a builtin class that has its (CPython) `Py_TPFLAGS_SEQUENCE` bit set
- a class that inherits from any of the above

The following standard library classes are sequences:

- `array.array`
- `collections.deque`
- `list`
- `memoryview`
- `range`
- `tuple`

### Note

Subject values of type `str`, `bytes`, and `bytearray` do not match sequence patterns.

## 3

In pattern matching, a mapping is defined as one of the following:

- a class that inherits from `collections.abc.Mapping`
- a Python class that has been registered as `collections.abc.Mapping`
- a builtin class that has its (CPython) `Py_TPFLAGS_MAPPING` bit set
- a class that inherits from any of the above

The standard library classes `dict` and `types.MappingProxyType` are mappings.

## 4

A string literal appearing as the first statement in the function body is transformed into the function's `__doc__` attribute and therefore the function's `docstring`.

## 5

A string literal appearing as the first statement in the class body is transformed into the namespace's `__doc__` item and therefore the class's `docstring`.

## 9. Top-level components

The Python interpreter can get its input from a number of sources: from a script passed to it as standard input or as program argument, typed in interactively, from a module source file, etc. This chapter gives the syntax used in these cases.

### 9.1. Complete Python programs

While a language specification need not prescribe how the language interpreter is invoked, it is useful to have a notion of a complete Python program. A complete Python program is executed in a minimally initialized environment: all built-in and standard modules are available, but none have been initialized, except for `sys` (various system services), `builtins` (built-in functions, exceptions and `None`) and `__main__`. The latter is used to provide the local and global namespace for execution of the complete program.

The syntax for a complete Python program is that for file input, described in the next section.

The interpreter may also be invoked in interactive mode; in this case, it does not read and execute a complete program but reads and executes one statement (possibly compound) at a time. The initial environment is identical to that of a complete program; each statement is executed in the namespace of `__main__`.

A complete program can be passed to the interpreter in three forms: with the `-c string` command line option, as a file passed as the first command line argument, or as standard input. If the file or standard input is a tty device, the interpreter enters interactive mode; otherwise, it executes the file as a complete program.

### 9.2. File input

All input read from non-interactive files has the same form:

```
file_input ::= (NEWLINE | statement) *
```

This syntax is used in the following situations:

- when parsing a complete Python program (from a file or from a string);
- when parsing a module;
- when parsing a string passed to the `exec()` function;

## 9.3. Interactive input

Input in interactive mode is parsed using the following grammar:

```
interactive_input ::= [stmt_list] NEWLINE | compound_stmt
```

Note that a (top-level) compound statement must be followed by a blank line in interactive mode; this is needed to help the parser detect the end of the input.

## 9.4. Expression input

`eval()` is used for expression input. It ignores leading whitespace. The string argument to `eval()` must have the following form:

```
eval_input ::= expression_list NEWLINE *
```

# 10. Full Grammar specification

This is the full Python grammar, derived directly from the grammar used to generate the CPython parser (see [Grammar/python.gram](https://github.com/python/cpython/tree/3.11/Grammar/python.gram) [https://github.com/python/cpython/tree/3.11/Grammar/python.gram]). The version here omits details related to code generation and error recovery.

The notation is a mixture of [EBNF](https://en.wikipedia.org/wiki/Extended_Backus%E2%80%93Naur_form) [https://en.wikipedia.org/wiki/Extended\_Backus%E2%80%93Naur\_form] and [PEG](https://en.wikipedia.org/wiki/Parsing_expression_grammar) [https://en.wikipedia.org/wiki/Parsing\_expression\_grammar]. In particular, `&` followed by a symbol, token or parenthesized group indicates a positive lookahead (i.e., is required to match but not consumed), while `!` indicates a negative lookahead (i.e., is required *not* to match). We use the `|` separator to mean PEG's "ordered choice" (written as `/` in traditional PEG grammars). See [PEP 617](https://peps.python.org/pep-0617/) [https://peps.python.org/pep-0617/] for more details on the grammar's syntax.

```
# PEG grammar for Python
```

```
# ===== START OF THE GRAMMAR =====
```

```
# General grammatical elements and rules:
```

```
#
# * Strings with double quotes (") denote SOFT KEYWORDS
# * Strings with single quotes (') denote KEYWORDS
# * Upper case names (NAME) denote tokens in the Grammar
# * Rule names starting with "invalid_" are used for spe
#     - These rules are NOT used in the first pass of th
#     - Only if the first pass fails to parse, a second
#       rules will be executed.
#     - If the parser fails in the second phase with a g
#       location of the generic failure of the first pas
```

```

#         reporting incorrect locations due to the invalid
#         - The order of the alternatives involving invalid
#         (like any rule in PEG).
#
# Grammar Syntax (see PEP 617 for more information):
#
# rule_name: expression
#     Optionally, a type can be included right after the rule name.
#     specifies the return type of the C or Python function.
#     rule:
# rule_name[return_type]: expression
#     If the return type is omitted, then a void * is returned.
#     Python.
# e1 e2
#     Match e1, then match e2.
# e1 | e2
#     Match e1 or e2.
#     The first alternative can also appear on the line after the first
#     for formatting purposes. In that case, a | must be used for the
#     alternative, like so:
#         rule_name[return_type]:
#             | first_alt
#             | second_alt
# ( e )
#     Match e (allows also to use other operators in the grammar).
# [ e ] or e?
#     Optionally match e.
# e*
#     Match zero or more occurrences of e.
# e+
#     Match one or more occurrences of e.
# s.e+
#     Match one or more occurrences of e, separated by s.
#     s does not include the separator. This is otherwise identical to
#     &e
#     Succeed if e can be parsed, without consuming any input.
# !e
#     Fail if e can be parsed, without consuming any input.

```

```

# ~
#   Commit to the current alternative, even if it fails
#

# The Python Standard Library

While [The Python Language Reference](#) describes the exact syntax and semantics of the Python language, this library reference manual describes the standard library that is distributed with Python. It also describes some of the optional components that are commonly included in Python distributions.

Python's standard library is very extensive, offering a wide range of facilities as indicated by the long table of contents listed below. The library contains built-in modules (written in C) that provide access to system functionality such as file I/O that would otherwise be inaccessible to Python programmers, as well as modules written in Python that provide standardized solutions for many problems that occur in everyday programming. Some of these modules are explicitly designed to encourage and enhance the portability of Python programs by abstracting away platform-specifics into platform-neutral APIs.

The Python installers for the Windows platform usually include the entire standard library and often also include many additional components. For Unix-like operating systems Python is normally provided as a collection of packages, so it may be necessary to use the packaging tools provided with the operating system to obtain some or all of the optional components.

In addition to the standard library, there is an active collection of hundreds of thousands of components (from individual programs and modules to packages and entire application development frameworks), available from the [Python Package Index](https://pypi.org) [https://pypi.org].

- [Introduction](#)
  - [Notes on availability](#)
- [Built-in Functions](#)

- Built-in Constants
  - Constants added by the `site` module
- Built-in Types
  - Truth Value Testing
  - Boolean Operations — `and`, `or`, `not`
  - Comparisons
  - Numeric Types — `int`, `float`, `complex`
  - Iterator Types
  - Sequence Types — `list`, `tuple`, `range`
  - Text Sequence Type — `str`
  - Binary Sequence Types — `bytes`, `bytearray`, `memoryview`
  - Set Types — `set`, `frozenset`
  - Mapping Types — `dict`
  - Context Manager Types
  - Type Annotation Types — Generic Alias, Union
  - Other Built-in Types
  - Special Attributes
  - Integer string conversion length limitation
- Built-in Exceptions
  - Exception context
  - Inheriting from built-in exceptions
  - Base classes
  - Concrete exceptions
  - Warnings
  - Exception groups
  - Exception hierarchy
- Text Processing Services
  - `string` — Common string operations
  - `re` — Regular expression operations
  - `difflib` — Helpers for computing deltas
  - `textwrap` — Text wrapping and filling
  - `unicodedata` — Unicode Database
  - `stringprep` — Internet String Preparation

- **readline** — GNU readline interface
- **rlcompleter** — Completion function for GNU readline
- Binary Data Services
  - **struct** — Interpret bytes as packed binary data
  - **codecs** — Codec registry and base classes
- Data Types
  - **datetime** — Basic date and time types
  - **zoneinfo** — IANA time zone support
  - **calendar** — General calendar-related functions
  - **collections** — Container datatypes
  - **collections.abc** — Abstract Base Classes for Containers
  - **heapq** — Heap queue algorithm
  - **bisect** — Array bisection algorithm
  - **array** — Efficient arrays of numeric values
  - **weakref** — Weak references
  - **types** — Dynamic type creation and names for built-in types
  - **copy** — Shallow and deep copy operations
  - **pprint** — Data pretty printer
  - **reprlib** — Alternate **repr()** implementation
  - **enum** — Support for enumerations
  - **graphlib** — Functionality to operate with graph-like structures
- Numeric and Mathematical Modules
  - **numbers** — Numeric abstract base classes
  - **math** — Mathematical functions
  - **cmath** — Mathematical functions for complex numbers
  - **decimal** — Decimal fixed point and floating point arithmetic
  - **fractions** — Rational numbers
  - **random** — Generate pseudo-random numbers
  - **statistics** — Mathematical statistics functions

- Functional Programming Modules
  - **itertools** — Functions creating iterators for efficient looping
  - **functools** — Higher-order functions and operations on callable objects
  - **operator** — Standard operators as functions
- File and Directory Access
  - **pathlib** — Object-oriented filesystem paths
  - **os.path** — Common pathname manipulations
  - **fileinput** — Iterate over lines from multiple input streams
  - **stat** — Interpreting **stat()** results
  - **filecmp** — File and Directory Comparisons
  - **tempfile** — Generate temporary files and directories
  - **glob** — Unix style pathname pattern expansion
  - **fnmatch** — Unix filename pattern matching
  - **linecache** — Random access to text lines
  - **shutil** — High-level file operations
- Data Persistence
  - **pickle** — Python object serialization
  - **copyreg** — Register **pickle** support functions
  - **shelve** — Python object persistence
  - **marshal** — Internal Python object serialization
  - **dbm** — Interfaces to Unix “databases”
  - **sqlite3** — DB-API 2.0 interface for SQLite databases
- Data Compression and Archiving
  - **zlib** — Compression compatible with **gzip**
  - **gzip** — Support for **gzip** files
  - **bz2** — Support for **bzip2** compression
  - **lzma** — Compression using the LZMA algorithm
  - **zipfile** — Work with ZIP archives
  - **tarfile** — Read and write tar archive files
- File Formats

- **csv** — CSV File Reading and Writing
- **configparser** — Configuration file parser
- **tomllib** — Parse TOML files
- **netrc** — netrc file processing
- **plistlib** — Generate and parse Apple **.plist** files
- Cryptographic Services
  - **hashlib** — Secure hashes and message digests
  - **hmac** — Keyed-Hashing for Message Authentication
  - **secrets** — Generate secure random numbers for managing secrets
- Generic Operating System Services
  - **os** — Miscellaneous operating system interfaces
  - **io** — Core tools for working with streams
  - **time** — Time access and conversions
  - **argparse** — Parser for command-line options, arguments and sub-commands
  - **getopt** — C-style parser for command line options
  - **logging** — Logging facility for Python
  - **logging.config** — Logging configuration
  - **logging.handlers** — Logging handlers
  - **getpass** — Portable password input
  - **curses** — Terminal handling for character-cell displays
  - **curses.textpad** — Text input widget for curses programs
  - **curses.ascii** — Utilities for ASCII characters
  - **curses.panel** — A panel stack extension for curses
  - **platform** — Access to underlying platform's identifying data
  - **errno** — Standard errno system symbols
  - **ctypes** — A foreign function library for Python
- Concurrent Execution
  - **threading** — Thread-based parallelism
  - **multiprocessing** — Process-based parallelism
  - **multiprocessing.shared\_memory** — Shared

- memory for direct access across processes
- The **concurrent** package
- **concurrent.futures** — Launching parallel tasks
- **subprocess** — Subprocess management
- **sched** — Event scheduler
- **queue** — A synchronized queue class
- **contextvars** — Context Variables
- **\_thread** — Low-level threading API
- Networking and Interprocess Communication
  - **asyncio** — Asynchronous I/O
  - **socket** — Low-level networking interface
  - **ssl** — TLS/SSL wrapper for socket objects
  - **select** — Waiting for I/O completion
  - **selectors** — High-level I/O multiplexing
  - **signal** — Set handlers for asynchronous events
  - **mmap** — Memory-mapped file support
- Internet Data Handling
  - **email** — An email and MIME handling package
  - **json** — JSON encoder and decoder
  - **mailbox** — Manipulate mailboxes in various formats
  - **mimetypes** — Map filenames to MIME types
  - **base64** — Base16, Base32, Base64, Base85 Data Encodings
  - **binascii** — Convert between binary and ASCII
  - **quopri** — Encode and decode MIME quoted-printable data
- Structured Markup Processing Tools
  - **html** — HyperText Markup Language support
  - **html.parser** — Simple HTML and XHTML parser
  - **html.entities** — Definitions of HTML general entities
  - XML Processing Modules
  - **xml.etree.ElementTree** — The ElementTree XML API
  - **xml.dom** — The Document Object Model API

- **xml.dom.minidom** — Minimal DOM implementation
  - **xml.dom.pulldom** — Support for building partial DOM trees
  - **xml.sax** — Support for SAX2 parsers
  - **xml.sax.handler** — Base classes for SAX handlers
  - **xml.sax.saxutils** — SAX Utilities
  - **xml.sax.xmlreader** — Interface for XML parsers
  - **xml.parsers.expat** — Fast XML parsing using Expat
- Internet Protocols and Support
    - **webbrowser** — Convenient web-browser controller
    - **wsgiref** — WSGI Utilities and Reference Implementation
    - **urllib** — URL handling modules
    - **urllib.request** — Extensible library for opening URLs
    - **urllib.response** — Response classes used by urllib
    - **urllib.parse** — Parse URLs into components
    - **urllib.error** — Exception classes raised by urllib.request
    - **urllib.robotparser** — Parser for robots.txt
    - **http** — HTTP modules
    - **http.client** — HTTP protocol client
    - **ftplib** — FTP protocol client
    - **poplib** — POP3 protocol client
    - **imaplib** — IMAP4 protocol client
    - **smtplib** — SMTP protocol client
    - **uuid** — UUID objects according to **RFC 4122**
    - **socketserver** — A framework for network servers
    - **http.server** — HTTP servers
    - **http.cookies** — HTTP state management
    - **http.cookiejar** — Cookie handling for HTTP clients
    - **xmlrpc** — XMLRPC server and client modules
    - **xmlrpc.client** — XML-RPC client access
    - **xmlrpc.server** — Basic XML-RPC servers
    - **ipaddress** — IPv4/IPv6 manipulation library
  - Multimedia Services
    - **wave** — Read and write WAV files

- **colorsys** — Conversions between color systems
- Internationalization
  - **gettext** — Multilingual internationalization services
  - **locale** — Internationalization services
- Program Frameworks
  - **turtle** — Turtle graphics
  - **cmd** — Support for line-oriented command interpreters
  - **shlex** — Simple lexical analysis
- Graphical User Interfaces with Tk
  - **tkinter** — Python interface to Tcl/Tk
  - **tkinter.colorchooser** — Color choosing dialog
  - **tkinter.font** — Tkinter font wrapper
  - Tkinter Dialogs
  - **tkinter.messagebox** — Tkinter message prompts
  - **tkinter.scrolledtext** — Scrolled Text Widget
  - **tkinter.dnd** — Drag and drop support
  - **tkinter.ttk** — Tk themed widgets
  - **tkinter.tix** — Extension widgets for Tk
  - IDLE
- Development Tools
  - **typing** — Support for type hints
  - **pydoc** — Documentation generator and online help system
  - Python Development Mode
  - Effects of the Python Development Mode
  - ResourceWarning Example
  - Bad file descriptor error example
  - **doctest** — Test interactive Python examples
  - **unittest** — Unit testing framework
  - **unittest.mock** — mock object library
  - **unittest.mock** — getting started
  - 2to3 — Automated Python 2 to 3 code translation
  - **test** — Regression tests package for Python

- **test.support** — Utilities for the Python test suite
- **test.support.socket\_helper** — Utilities for socket tests
- **test.support.script\_helper** — Utilities for the Python execution tests
- **test.support.bytecode\_helper** — Support tools for testing correct bytecode generation
- **test.support.threading\_helper** — Utilities for threading tests
- **test.support.os\_helper** — Utilities for os tests
- **test.support.import\_helper** — Utilities for import tests
- **test.support.warnings\_helper** — Utilities for warnings tests
- Debugging and Profiling
  - Audit events table
  - **bdb** — Debugger framework
  - **faulthandler** — Dump the Python traceback
  - **pdb** — The Python Debugger
  - The Python Profilers
  - **timeit** — Measure execution time of small code snippets
  - **trace** — Trace or track Python statement execution
  - **tracemalloc** — Trace memory allocations
- Software Packaging and Distribution
  - **distutils** — Building and installing Python modules
  - **ensurepip** — Bootstrapping the **pip** installer
  - **venv** — Creation of virtual environments
  - **zipapp** — Manage executable Python zip archives
- Python Runtime Services
  - **sys** — System-specific parameters and functions
  - **sysconfig** — Provide access to Python's configuration information
  - **builtins** — Built-in objects
  - **\_\_main\_\_** — Top-level code environment

- **warnings** — Warning control
- **dataclasses** — Data Classes
- **contextlib** — Utilities for **with**-statement contexts
- **abc** — Abstract Base Classes
- **atexit** — Exit handlers
- **traceback** — Print or retrieve a stack traceback
- **\_\_future\_\_** — Future statement definitions
- **gc** — Garbage Collector interface
- **inspect** — Inspect live objects
- **site** — Site-specific configuration hook
- Custom Python Interpreters
  - **code** — Interpreter base classes
  - **codeop** — Compile Python code
- Importing Modules
  - **zipimport** — Import modules from Zip archives
  - **pkgutil** — Package extension utility
  - **modulefinder** — Find modules used by a script
  - **runpy** — Locating and executing Python modules
  - **importlib** — The implementation of **import**
  - **importlib.resources** – Resources
  - Deprecated functions
  - **importlib.resources.abc** – Abstract base classes for resources
  - Using **importlib.metadata**
  - The initialization of the **sys.path** module search path
- Python Language Services
  - **ast** — Abstract Syntax Trees
  - **symtable** — Access to the compiler's symbol tables
  - **token** — Constants used with Python parse trees
  - **keyword** — Testing for Python keywords
  - **tokenize** — Tokenizer for Python source
  - **tabnanny** — Detection of ambiguous indentation
  - **pyclbr** — Python module browser support
  - **py\_compile** — Compile Python source files
  - **compileall** — Byte-compile Python libraries

- **dis** — Disassembler for Python bytecode
- **pickletools** — Tools for pickle developers
- MS Windows Specific Services
  - **msvcrt** — Useful routines from the MS VC++ runtime
  - **winreg** — Windows registry access
  - **winsound** — Sound-playing interface for Windows
- Unix Specific Services
  - **posix** — The most common POSIX system calls
  - **pwd** — The password database
  - **grp** — The group database
  - **termios** — POSIX style tty control
  - **tty** — Terminal control functions
  - **pty** — Pseudo-terminal utilities
  - **fcntl** — The **fcntl** and **ioctl** system calls
  - **resource** — Resource usage information
  - **syslog** — Unix syslog library routines
- Superseded Modules
  - **aifc** — Read and write AIFF and AIFC files
  - **asynchat** — Asynchronous socket command/response handler
  - **asyncore** — Asynchronous socket handler
  - **audioop** — Manipulate raw audio data
  - **cgi** — Common Gateway Interface support
  - **cgitb** — Traceback manager for CGI scripts
  - **chunk** — Read IFF chunked data
  - **crypt** — Function to check Unix passwords
  - **imghdr** — Determine the type of an image
  - **imp** — Access the import internals
  - **mailcap** — Mailcap file handling
  - **msilib** — Read and write Microsoft Installer files
  - **nis** — Interface to Sun's NIS (Yellow Pages)
  - **nntplib** — NNTP protocol client
  - **optparse** — Parser for command line options
  - **ossaudiodev** — Access to OSS-compatible audio

devices

- **pipes** — Interface to shell pipelines
- **smtpd** — SMTP Server
- **sndhdr** — Determine type of sound file
- **spwd** — The shadow password database
- **sunau** — Read and write Sun AU files
- **telnetlib** — Telnet client
- **uu** — Encode and decode uuencode files
- **xdrlib** — Encode and decode XDR data

- Security Considerations

# Introduction

The “Python library” contains several different kinds of components.

It contains data types that would normally be considered part of the “core” of a language, such as numbers and lists. For these types, the Python language core defines the form of literals and places some constraints on their semantics, but does not fully define the semantics. (On the other hand, the language core does define syntactic properties like the spelling and priorities of operators.)

The library also contains built-in functions and exceptions — objects that can be used by all Python code without the need of an `import` statement. Some of these are defined by the core language, but many are not essential for the core semantics and are only described here.

The bulk of the library, however, consists of a collection of modules. There are many ways to dissect this collection. Some modules are written in C and built in to the Python interpreter; others are written in Python and imported in source form. Some modules provide interfaces that are highly specific to Python, like printing a stack trace; some provide interfaces that are specific to particular operating systems, such as access to specific hardware; others provide interfaces that are specific to a particular application domain, like the World Wide Web. Some modules are available in all versions and ports of Python; others are only available when the underlying system supports or requires them; yet others are available only when a particular configuration option was chosen at the time when Python was compiled and installed.

This manual is organized “from the inside out:” it first describes the built-in functions, data types and exceptions, and finally the modules, grouped in chapters of related modules.

This means that if you start reading this manual from the start, and

skip to the next chapter when you get bored, you will get a reasonable overview of the available modules and application areas that are supported by the Python library. Of course, you don't *have* to read it like a novel — you can also browse the table of contents (in front of the manual), or look for a specific function, module or term in the index (in the back). And finally, if you enjoy learning about random subjects, you choose a random page number (see module [random](#)) and read a section or two. Regardless of the order in which you read the sections of this manual, it helps to start with chapter [Built-in Functions](#), as the remainder of the manual assumes familiarity with this material.

Let the show begin!

## Notes on availability

- An “Availability: Unix” note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim “Availability: Unix” are supported on macOS, which builds on a Unix core.
- If an availability note contains both a minimum Kernel version and a minimum libc version, then both conditions must hold. For example a feature with note *Availability: Linux >= 3.17 with glibc >= 2.27* requires both Linux 3.17 or newer and glibc 2.27 or newer.

## WebAssembly platforms

The [WebAssembly](https://webassembly.org/) [https://webassembly.org/] platforms `wasm32-emscripten` ([Emscripten](https://emscripten.org/) [https://emscripten.org/]) and `wasm32-wasi` ([WASI](https://wasi.dev/) [https://wasi.dev/]) provide a subset of POSIX APIs. WebAssembly runtimes and browsers are sandboxed and have limited access to the host and external resources. Any Python standard library module that uses processes, threading, networking, signals, or other forms of inter-process communication (IPC), is either not available or may not work as on other Unix-like systems. File I/O, file system, and Unix permission-related functions are restricted, too. Emscripten does not permit blocking I/O. Other

blocking operations like `sleep()` block the browser event loop.

The properties and behavior of Python on WebAssembly platforms depend on the [Emscripten](https://emscripten.org/) [https://emscripten.org/] SDK or [WASI](https://wasi.dev/) [https://wasi.dev/] SDK version, WASM runtimes (browser, NodeJS, [wasmtime](https://wasmtime.dev/) [https://wasmtime.dev/]), and Python build time flags. WebAssembly, Emscripten, and WASI are evolving standards; some features like networking may be supported in the future.

For Python in the browser, users should consider [Pyodide](https://pyodide.org/) [https://pyodide.org/] or [PyScript](https://pyscript.net/) [https://pyscript.net/]. PyScript is built on top of Pyodide, which itself is built on top of CPython and Emscripten. Pyodide provides access to browsers' JavaScript and DOM APIs as well as limited networking capabilities with JavaScript's XMLHttpRequest and Fetch APIs.

- Process-related APIs are not available or always fail with an error. That includes APIs that spawn new processes (`fork()`, `execve()`), wait for processes (`waitpid()`), send signals (`kill()`), or otherwise interact with processes. The `subprocess` is importable but does not work.
- The `socket` module is available, but is limited and behaves differently from other platforms. On Emscripten, sockets are always non-blocking and require additional JavaScript code and helpers on the server to proxy TCP through WebSockets; see [Emscripten Networking](https://emscripten.org/docs/porting/networking.html) [https://emscripten.org/docs/porting/networking.html] for more information. WASI snapshot preview 1 only permits sockets from an existing file descriptor.
- Some functions are stubs that either don't do anything and always return hardcoded values.
- Functions related to file descriptors, file permissions, file ownership, and links are limited and don't support some operations. For example, WASI does not permit symlinks with absolute file names.

## Built-in Functions

The Python interpreter has a number of functions and types built into it that are always available. They are listed here in alphabetical order.

## Built-in Functions

## R

[illegible]

`abs(x)`

Return the absolute value of a number. The argument may be an integer, a floating point number, or an object implementing `__abs__()`. If the argument is a complex number, its magnitude is returned.

`aiter(async_iterable)`

Return an [asynchronous iterator](#) for an [asynchronous iterable](#). Equivalent to calling `x.__aiter__()`.

Note: Unlike `iter()`, `aiter()` has no 2-argument variant.

*New in version 3.10.*

`all(iterable)`

Return `True` if all elements of the *iterable* are true (or if the iterable is empty). Equivalent to:

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

`awaitable anext(async_iterator)`

`awaitable anext(async_iterator, default)`

When awaited, return the next item from the given [asynchronous iterator](#), or *default* if given and the iterator is exhausted.

This is the async variant of the `next()` builtin, and behaves similarly.

This calls the `__anext__()` method of *async\_iterator*, returning an [awaitable](#). Awaiting this returns the next value of the iterator. If *default* is given, it is returned if the iterator is exhausted, otherwise [StopAsyncIteration](#) is raised.

*New in version 3.10.*

### `any(iterable)`

Return `True` if any element of the *iterable* is true. If the *iterable* is empty, return `False`. Equivalent to:

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

### `ascii(object)`

As `repr()`, return a string containing a printable representation of an object, but escape the non-ASCII characters in the string returned by `repr()` using `\x`, `\u`, or `\U` escapes. This generates a string similar to that returned by `repr()` in Python 2.

### `bin(x)`

Convert an integer number to a binary string prefixed with “0b”. The result is a valid Python expression. If *x* is not a Python `int` object, it has to define an `__index__()` method that returns an integer. Some examples:

```
>>> bin(3)
'0b11'
>>> bin(-10)
'-0b1010'
```

If the prefix “0b” is desired or not, you can use either of the following ways.

```
>>> format(14, '#b'), format(14, 'b')
('0b1110', '1110')
>>> f'{14:#b}', f'{14:b}'
('0b1110', '1110')
```

See also `format()` for more information.

`class bool(x=False)`

Return a Boolean value, i.e. one of `True` or `False`. `x` is converted using the standard [truth testing procedure](#). If `x` is false or omitted, this returns `False`; otherwise, it returns `True`. The `bool` class is a subclass of `int` (see [Numeric Types — int, float, complex](#)). It cannot be subclassed further. Its only instances are `False` and `True` (see [Boolean Values](#)).

*Changed in version 3.7:* `x` is now a positional-only parameter.

`breakpoint(*args, **kws)`

This function drops you into the debugger at the call site. Specifically, it calls `sys.breakpointhook()`, passing `args` and `kws` straight through. By default, `sys.breakpointhook()` calls `pdb.set_trace()` expecting no arguments. In this case, it is purely a convenience function so you don't have to explicitly import `pdb` or type as much code to enter the debugger. However, `sys.breakpointhook()` can be set to some other function and `breakpoint()` will automatically call that, allowing you to drop into the debugger of choice. If `sys.breakpointhook()` is not accessible, this function will raise `RuntimeError`.

By default, the behavior of `breakpoint()` can be changed with the `PYTHONBREAKPOINT` environment variable. See `sys.breakpointhook()` for usage details.

Note that this is not guaranteed if `sys.breakpointhook()` has been replaced.

Raises an [auditing event](#) `builtins.breakpoint` with argument `breakpointhook`.

*New in version 3.7.*

`class bytearray(source=b'')`

`class bytearray(source, encoding)`

`class bytearray(source, encoding, errors)`

Return a new array of bytes. The `bytearray` class is a mutable sequence of integers in the range  $0 \leq x < 256$ . It has most of the usual methods of mutable sequences, described in [Mutable Sequence Types](#), as well as most methods that the `bytes` type has, see [Bytes and Bytearray Operations](#).

The optional *source* parameter can be used to initialize the array in a few different ways:

- If it is a *string*, you must also give the *encoding* (and optionally, *errors*) parameters; `bytearray()` then converts the string to bytes using `str.encode()`.
- If it is an *integer*, the array will have that size and will be initialized with null bytes.
- If it is an object conforming to the [buffer interface](#), a read-only buffer of the object will be used to initialize the bytes array.
- If it is an *iterable*, it must be an iterable of integers in the range  $0 \leq x < 256$ , which are used as the initial contents of the array.

Without an argument, an array of size 0 is created.

See also [Binary Sequence Types — bytes, bytearray, memoryview and Bytearray Objects](#).

```
class bytes(source=b")
class bytes(source, encoding)
class bytes(source, encoding, errors)
```

Return a new “bytes” object which is an immutable sequence of integers in the range  $0 \leq x < 256$ . `bytes` is an immutable version of `bytearray` – it has the same non-mutating methods and the same indexing and slicing behavior.

Accordingly, constructor arguments are interpreted as for `bytearray()`.

Bytes objects can also be created with literals, see [String and](#)

Bytes literals.

See also [Binary Sequence Types — bytes, bytearray, memoryview](#), [Bytes Objects](#), and [Bytes and Bytearray Operations](#).

`callable(object)`

Return **True** if the *object* argument appears callable, **False** if not. If this returns **True**, it is still possible that a call fails, but if it is **False**, calling *object* will never succeed. Note that classes are callable (calling a class returns a new instance); instances are callable if their class has a `__call__()` method.

*New in version 3.2:* This function was first removed in Python 3.0 and then brought back in Python 3.2.

`chr(i)`

Return the string representing a character whose Unicode code point is the integer *i*. For example, `chr(97)` returns the string `'a'`, while `chr(8364)` returns the string `'€'`. This is the inverse of `ord()`.

The valid range for the argument is from 0 through 1,114,111 (0x10FFFF in base 16). **ValueError** will be raised if *i* is outside that range.

`@classmethod`

Transform a method into a class method.

A class method receives the class as an implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom:

```
class C:
    @classmethod
    def f(cls, arg1, arg2): ...
```

The `@classmethod` form is a function [decorator](#) – see

[Function definitions](#) for details.

A class method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Class methods are different than C++ or Java static methods. If you want those, see [staticmethod\(\)](#) in this section. For more information on class methods, see [The standard type hierarchy](#).

*Changed in version 3.9:* Class methods can now wrap other [descriptors](#) such as [property\(\)](#).

*Changed in version 3.10:* Class methods now inherit the method attributes (`__module__`, `__name__`, `__qualname__`, `__doc__` and `__annotations__`) and have a new `__wrapped__` attribute.

*Changed in version 3.11:* Class methods can no longer wrap other [descriptors](#) such as [property\(\)](#).

`compile(source, filename, mode, flags=0, dont_inherit=False, optimize=-1)`

Compile the *source* into a code or AST object. Code objects can be executed by [exec\(\)](#) or [eval\(\)](#). *source* can either be a normal string, a byte string, or an AST object. Refer to the [ast](#) module documentation for information on how to work with AST objects.

The *filename* argument should give the file from which the code was read; pass some recognizable value if it wasn't read from a file ('<string>' is commonly used).

The *mode* argument specifies what kind of code must be compiled; it can be 'exec' if *source* consists of a sequence of statements, 'eval' if it consists of a single expression, or 'single' if it consists of a single interactive statement (in

the latter case, expression statements that evaluate to something other than `None` will be printed).

The optional arguments *flags* and *dont\_inherit* control which [compiler options](#) should be activated and which [future features](#) should be allowed. If neither is present (or both are zero) the code is compiled with the same flags that affect the code that is calling `compile()`. If the *flags* argument is given and *dont\_inherit* is not (or is zero) then the compiler options and the future statements specified by the *flags* argument are used in addition to those that would be used anyway. If *dont\_inherit* is a non-zero integer then the *flags* argument is it – the flags (future features and compiler options) in the surrounding code are ignored.

Compiler options and future statements are specified by bits which can be bitwise ORed together to specify multiple options. The bitfield required to specify a given future feature can be found as the `compiler_flag` attribute on the `_Feature` instance in the `__future__` module. [Compiler flags](#) can be found in `ast` module, with `PyCF_` prefix.

The argument *optimize* specifies the optimization level of the compiler; the default value of `-1` selects the optimization level of the interpreter as given by `-O` options. Explicit levels are `0` (no optimization; `__debug__` is true), `1` (asserts are removed, `__debug__` is false) or `2` (docstrings are removed too).

This function raises [SyntaxError](#) if the compiled source is invalid, and [ValueError](#) if the source contains null bytes.

If you want to parse Python code into its AST representation, see `ast.parse()`.

Raises an [auditing event](#) `compile` with arguments `source` and `filename`. This event may also be raised by implicit compilation.

## Note

When compiling a string with multi-line code in 'single' or 'eval' mode, input must be terminated by at least one newline character. This is to facilitate detection of incomplete and complete statements in the `code` module.

### Warning

It is possible to crash the Python interpreter with a sufficiently large/complex string when compiling to an AST object due to stack depth limitations in Python's AST compiler.

*Changed in version 3.2:* Allowed use of Windows and Mac newlines. Also, input in 'exec' mode does not have to end in a newline anymore. Added the *optimize* parameter.

*Changed in version 3.5:* Previously, `TypeError` was raised when null bytes were encountered in *source*.

*New in version 3.8:* `ast.PyCF_ALLOW_TOP_LEVEL_AWAIT` can now be passed in flags to enable support for top-level await, `async for`, and `async with`.

*class* `complex(real=0, imag=0)`

*class* `complex(string)`

Return a complex number with the value  $real + imag*1j$  or convert a string or number to a complex number. If the first parameter is a string, it will be interpreted as a complex number and the function must be called without a second parameter. The second parameter can never be a string. Each argument may be any numeric type (including complex). If *imag* is omitted, it defaults to zero and the constructor serves as a numeric conversion like `int` and `float`. If both arguments are omitted, returns `0j`.

For a general Python object `x`, `complex(x)` delegates to `x.__complex__()`. If `__complex__()` is not defined then it falls back to `__float__()`. If `__float__()` is not

defined then it falls back to `__index__()`.

### Note

When converting from a string, the string must not contain whitespace around the central `+` or `-` operator. For example, `complex('1+2j')` is fine, but `complex('1 + 2j')` raises `ValueError`.

The complex type is described in [Numeric Types — int, float, complex](#).

*Changed in version 3.6:* Grouping digits with underscores as in code literals is allowed.

*Changed in version 3.8:* Falls back to `__index__()` if `__complex__()` and `__float__()` are not defined.

`delattr(object, name)`

This is a relative of `setattr()`. The arguments are an object and a string. The string must be the name of one of the object's attributes. The function deletes the named attribute, provided the object allows it. For example, `delattr(x, 'foobar')` is equivalent to `del x.foobar`. *name* need not be a Python identifier (see `setattr()`).

`class dict(**kwarg)`

`class dict(mapping, **kwarg)`

`class dict(iterable, **kwarg)`

Create a new dictionary. The `dict` object is the dictionary class. See `dict` and [Mapping Types — dict](#) for documentation about this class.

For other containers see the built-in `list`, `set`, and `tuple` classes, as well as the `collections` module.

`dir()`

`dir(object)`

Without arguments, return the list of names in the current local scope. With an argument, attempt to return a list of valid attributes for that object.

If the object has a method named `__dir__()`, this method will be called and must return the list of attributes. This allows objects that implement a custom `__getattr__()` or `__getattribute__()` function to customize the way `dir()` reports their attributes.

If the object does not provide `__dir__()`, the function tries its best to gather information from the object's `__dict__` attribute, if defined, and from its type object. The resulting list is not necessarily complete and may be inaccurate when the object has a custom `__getattr__()`.

The default `dir()` mechanism behaves differently with different types of objects, as it attempts to produce the most relevant, rather than complete, information:

- If the object is a module object, the list contains the names of the module's attributes.
- If the object is a type or class object, the list contains the names of its attributes, and recursively of the attributes of its bases.
- Otherwise, the list contains the object's attributes' names, the names of its class's attributes, and recursively of the attributes of its class's base classes.

The resulting list is sorted alphabetically. For example:

```
>>> import struct
>>> dir()      # show the names in the module namespace
['__builtin__', '__name__', 'struct']
>>> dir(struct)  # show the names in the struct module
['Struct', '__all__', '__builtin__', '__cached__',
 '__initializing__', '__loader__', '__name__', '__package__',
 '__clearcache__', 'calcsize', 'error', 'pack', 'pack_1',
 'unpack', 'unpack_from']
>>> class Shape:
...     def __dir__(self):
```

```
...         return ['area', 'perimeter', 'location']
>>> s = Shape()
>>> dir(s)
['area', 'location', 'perimeter']
```

## Note

Because `dir()` is supplied primarily as a convenience for use at an interactive prompt, it tries to supply an interesting set of names more than it tries to supply a rigorously or consistently defined set of names, and its detailed behavior may change across releases. For example, metaclass attributes are not in the result list when the argument is a class.

## `divmod(a, b)`

Take two (non-complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using integer division. With mixed operand types, the rules for binary arithmetic operators apply. For integers, the result is the same as  $(a // b, a \% b)$ . For floating point numbers the result is  $(q, a \% b)$ , where  $q$  is usually `math.floor(a / b)` but may be 1 less than that. In any case  $q * b + a \% b$  is very close to  $a$ , if  $a \% b$  is non-zero it has the same sign as  $b$ , and  $0 \leq \text{abs}(a \% b) < \text{abs}(b)$ .

## `enumerate(iterable, start=0)`

Return an enumerate object. *iterable* must be a sequence, an [iterator](#), or some other object which supports iteration. The `__next__()` method of the iterator returned by `enumerate()` returns a tuple containing a count (from *start* which defaults to 0) and the values obtained from iterating over *iterable*.

```
>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Wi
```

```
>>> list(enumerate(seasons, start=1))  
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Wi
```

Equivalent to:

```
def enumerate(iterable, start=0):  
    n = start  
    for elem in iterable:  
        yield n, elem  
        n += 1
```

`eval(expression, globals=None, locals=None)`

The arguments are a string and optional globals and locals. If provided, *globals* must be a dictionary. If provided, *locals* can be any mapping object.

The *expression* argument is parsed and evaluated as a Python expression (technically speaking, a condition list) using the *globals* and *locals* dictionaries as global and local namespace. If the *globals* dictionary is present and does not contain a value for the key `__builtins__`, a reference to the dictionary of the built-in module `builtins` is inserted under that key before *expression* is parsed. That way you can control what builtins are available to the executed code by inserting your own `__builtins__` dictionary into *globals* before passing it to `eval()`. If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed with the *globals* and *locals* in the environment where `eval()` is called. Note, `eval()` does not have access to the `nested scopes` (non-locals) in the enclosing environment.

The return value is the result of the evaluated expression. Syntax errors are reported as exceptions. Example:

```
>>> x = 1  
>>> eval('x+1')  
2
```

This function can also be used to execute arbitrary code

objects (such as those created by `compile()`). In this case, pass a code object instead of a string. If the code object has been compiled with `'exec'` as the *mode* argument, `eval()`'s return value will be `None`.

Hints: dynamic execution of statements is supported by the `exec()` function. The `globals()` and `locals()` functions return the current global and local dictionary, respectively, which may be useful to pass around for use by `eval()` or `exec()`.

If the given source is a string, then leading and trailing spaces and tabs are stripped.

See `ast.literal_eval()` for a function that can safely evaluate strings with expressions containing only literals.

Raises an `auditing event` `exec` with the code object as the argument. Code compilation events may also be raised.

`exec(object, globals=None, locals=None, /, *, closure=None)`

This function supports dynamic execution of Python code. *object* must be either a string or a code object. If it is a string, the string is parsed as a suite of Python statements which is then executed (unless a syntax error occurs). <sup>1</sup> If it is a code object, it is simply executed. In all cases, the code that's executed is expected to be valid as file input (see the section [File input](#) in the Reference Manual). Be aware that the `nonlocal`, `yield`, and `return` statements may not be used outside of function definitions even within the context of code passed to the `exec()` function. The return value is `None`.

In all cases, if the optional parts are omitted, the code is executed in the current scope. If only *globals* is provided, it must be a dictionary (and not a subclass of dictionary), which will be used for both the global and the local variables. If *globals* and *locals* are given, they are used for the global and local variables, respectively. If provided, *locals* can be any mapping object. Remember that at the module level, *globals*

and *locals* are the same dictionary. If `exec` gets two separate objects as *globals* and *locals*, the code will be executed as if it were embedded in a class definition.

If the *globals* dictionary does not contain a value for the key `__builtins__`, a reference to the dictionary of the built-in module `builtins` is inserted under that key. That way you can control what builtins are available to the executed code by inserting your own `__builtins__` dictionary into *globals* before passing it to `exec()`.

The *closure* argument specifies a closure—a tuple of cellvars. It's only valid when the *object* is a code object containing free variables. The length of the tuple must exactly match the number of free variables referenced by the code object.

Raises an `auditing event` `exec` with the code object as the argument. Code compilation events may also be raised.

### Note

The built-in functions `globals()` and `locals()` return the current global and local dictionary, respectively, which may be useful to pass around for use as the second and third argument to `exec()`.

### Note

The default *locals* act as described for function `locals()` below: modifications to the default *locals* dictionary should not be attempted. Pass an explicit *locals* dictionary if you need to see effects of the code on *locals* after function `exec()` returns.

*Changed in version 3.11:* Added the *closure* parameter.

`filter(function, iterable)`

Construct an iterator from those elements of *iterable* for which *function* is true. *iterable* may be either a sequence, a container which supports iteration, or an iterator. If *function* is `None`,

the identity function is assumed, that is, all elements of *iterable* that are false are removed.

Note that `filter(function, iterable)` is equivalent to the generator expression `(item for item in iterable if function(item))` if `function` is not `None` and `(item for item in iterable if item)` if `function` is `None`.

See [itertools.filterfalse\(\)](#) for the complementary function that returns elements of *iterable* for which *function* is false.

*class* `float(x=0.0)`

Return a floating point number constructed from a number or string *x*.

If the argument is a string, it should contain a decimal number, optionally preceded by a sign, and optionally embedded in whitespace. The optional sign may be '+' or '-'; a '+' sign has no effect on the value produced. The argument may also be a string representing a NaN (not-a-number), or positive or negative infinity. More precisely, the input must conform to the `floatvalue` production rule in the following grammar, after leading and trailing whitespace characters are removed:

```
sign          ::= "+" | "-"
infinity      ::= "Infinity" | "inf"
nan           ::= "nan"
digitpart     ::= digit ("_" digit)*
number        ::= [digitpart] "." digitpart | digitpart
exponent      ::= ("e" | "E") ["+" | "-"] digitpart
floatnumber   ::= number [exponent]
floatvalue    ::= [sign] (floatnumber | infinity | nan)
```

Here `digit` is a Unicode decimal digit (character in the Unicode general category `Nd`). Case is not significant, so, for example, “inf”, “Inf”, “INFINITY”, and “iNfINity” are all acceptable spellings for positive infinity.

Otherwise, if the argument is an integer or a floating point number, a floating point number with the same value (within Python’s floating point precision) is returned. If the argument is outside the range of a Python float, an `OverflowError` will be raised.

For a general Python object `x`, `float(x)` delegates to `x.__float__()`. If `__float__()` is not defined then it falls back to `__index__()`.

If no argument is given, `0.0` is returned.

Examples:

```
>>> float('+1.23')
1.23
>>> float('    -12345\n')
-12345.0
>>> float('1e-003')
0.001
>>> float('+1E6')
1000000.0
>>> float('-Infinity')
-inf
```

The float type is described in [Numeric Types — int, float, complex](#).

*Changed in version 3.6:* Grouping digits with underscores as in code literals is allowed.

*Changed in version 3.7:* `x` is now a positional-only parameter.

*Changed in version 3.8:* Falls back to `__index__()` if `__float__()` is not defined.

`format(value, format_spec = "")`

Convert a *value* to a “formatted” representation, as controlled by *format\_spec*. The interpretation of *format\_spec* will depend on the type of the *value* argument; however, there is a

standard formatting syntax that is used by most built-in types: [Format Specification Mini-Language](#).

The default *format\_spec* is an empty string which usually gives the same effect as calling `str(value)`.

A call to `format(value, format_spec)` is translated to `type(value).__format__(value, format_spec)` which bypasses the instance dictionary when searching for the value's `__format__()` method. A [TypeError](#) exception is raised if the method search reaches [object](#) and the *format\_spec* is non-empty, or if either the *format\_spec* or the return value are not strings.

*Changed in version 3.4:*

`object().__format__(format_spec)` raises [TypeError](#) if *format\_spec* is not an empty string.

`class frozenset(iterable=set())`

Return a new [frozenset](#) object, optionally with elements taken from *iterable*. `frozenset` is a built-in class. See [frozenset](#) and [Set Types — set, frozenset](#) for documentation about this class.

For other containers see the built-in [set](#), [list](#), [tuple](#), and [dict](#) classes, as well as the [collections](#) module.

`getattr(object, name)`

`getattr(object, name, default)`

Return the value of the named attribute of *object*. *name* must be a string. If the string is the name of one of the object's attributes, the result is the value of that attribute. For example, `getattr(x, 'foobar')` is equivalent to `x.foobar`. If the named attribute does not exist, *default* is returned if provided, otherwise [AttributeError](#) is raised. *name* need not be a Python identifier (see [setattr\(\)](#)).

## Note

Since [private name mangling](#) happens at compilation time,

one must manually mangle a private attribute's (attributes with two leading underscores) name in order to retrieve it with `getattr()`.

## `globals()`

Return the dictionary implementing the current module namespace. For code within functions, this is set when the function is defined and remains the same regardless of where the function is called.

## `hasattr(object, name)`

The arguments are an object and a string. The result is `True` if the string is the name of one of the object's attributes, `False` if not. (This is implemented by calling `getattr(object, name)` and seeing whether it raises an `AttributeError` or not.)

## `hash(object)`

Return the hash value of the object (if it has one). Hash values are integers. They are used to quickly compare dictionary keys during a dictionary lookup. Numeric values that compare equal have the same hash value (even if they are of different types, as is the case for 1 and 1.0).

### **Note**

For objects with custom `__hash__()` methods, note that `hash()` truncates the return value based on the bit width of the host machine. See `__hash__()` for details.

## `help()`

### `help(request)`

Invoke the built-in help system. (This function is intended for interactive use.) If no argument is given, the interactive help system starts on the interpreter console. If the argument is a

string, then the string is looked up as the name of a module, function, class, method, keyword, or documentation topic, and a help page is printed on the console. If the argument is any other kind of object, a help page on the object is generated.

Note that if a slash(/) appears in the parameter list of a function when invoking `help()`, it means that the parameters prior to the slash are positional-only. For more info, see [the FAQ entry on positional-only parameters](#).

This function is added to the built-in namespace by the `site` module.

*Changed in version 3.4:* Changes to `pydoc` and `inspect` mean that the reported signatures for callables are now more comprehensive and consistent.

## `hex(x)`

Convert an integer number to a lowercase hexadecimal string prefixed with “0x”. If `x` is not a Python `int` object, it has to define an `__index__()` method that returns an integer. Some examples:

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

If you want to convert an integer number to an uppercase or lower hexadecimal string with prefix or not, you can use either of the following ways:

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'{255:#x}', f'{255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

See also `format()` for more information.

See also `int()` for converting a hexadecimal string to an integer using a base of 16.

### Note

To obtain a hexadecimal string representation for a float, use the `float.hex()` method.

### `id(object)`

Return the “identity” of an object. This is an integer which is guaranteed to be unique and constant for this object during its lifetime. Two objects with non-overlapping lifetimes may have the same `id()` value.

**CPython implementation detail:** This is the address of the object in memory.

Raises an `auditing event` `builtins.id` with argument `id`.

### `input()`

#### `input(prompt)`

If the *prompt* argument is present, it is written to standard output without a trailing newline. The function then reads a line from input, converts it to a string (stripping a trailing newline), and returns that. When EOF is read, `EOFError` is raised. Example:

```
>>> s = input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

If the `readline` module was loaded, then `input()` will use it to provide elaborate line editing and history features.

Raises an `auditing event` `builtins.input` with argument

prompt before reading input

Raises an [auditing event](#) `builtins.input/result` with the result after successfully reading input.

`class int(x=0)`

`class int(x, base=10)`

Return an integer object constructed from a number or string `x`, or return `0` if no arguments are given. If `x` defines [\\_\\_int\\_\\_\(\)](#), `int(x)` returns `x.__int__()`. If `x` defines [\\_\\_index\\_\\_\(\)](#), it returns `x.__index__()`. If `x` defines [\\_\\_trunc\\_\\_\(\)](#), it returns `x.__trunc__()`. For floating point numbers, this truncates towards zero.

If `x` is not a number or if `base` is given, then `x` must be a string, [bytes](#), or [bytearray](#) instance representing an integer in radix `base`. Optionally, the string can be preceded by `+` or `-` (with no space in between), have leading zeros, be surrounded by whitespace, and have single underscores interspersed between digits.

A base-`n` integer string contains digits, each representing a value from 0 to `n-1`. The values 0–9 can be represented by any Unicode decimal digit. The values 10–35 can be represented by `a` to `z` (or `A` to `Z`). The default `base` is 10. The allowed bases are 0 and 2–36. Base-2, -8, and -16 strings can be optionally prefixed with `0b/0B`, `0o/0O`, or `0x/0X`, as with integer literals in code. For base 0, the string is interpreted in a similar way to an [integer literal in code](#), in that the actual base is 2, 8, 10, or 16 as determined by the prefix. Base 0 also disallows leading zeros: `int('010', 0)` is not legal, while `int('010')` and `int('010', 8)` are.

The integer type is described in [Numeric Types — int, float, complex](#).

*Changed in version 3.4:* If `base` is not an instance of [int](#) and the `base` object has a [base.\\_\\_index\\_\\_](#) method, that method is called to obtain an integer for the base. Previous versions used [base.\\_\\_int\\_\\_](#) instead of

`base.__index__.`

*Changed in version 3.6:* Grouping digits with underscores as in code literals is allowed.

*Changed in version 3.7:* `x` is now a positional-only parameter.

*Changed in version 3.8:* Falls back to `__index__()` if `__int__()` is not defined.

*Changed in version 3.11:* The delegation to `__trunc__()` is deprecated.

*Changed in version 3.11:* `int` string inputs and string representations can be limited to help avoid denial of service attacks. A `ValueError` is raised when the limit is exceeded while converting a string `x` to an `int` or when converting an `int` into a string would exceed the limit. See the [integer string conversion length limitation](#) documentation.

`isinstance(object, classinfo)`

Return `True` if the *object* argument is an instance of the *classinfo* argument, or of a (direct, indirect, or [virtual](#)) subclass thereof. If *object* is not an object of the given type, the function always returns `False`. If *classinfo* is a tuple of type objects (or recursively, other such tuples) or a [Union Type](#) of multiple types, return `True` if *object* is an instance of any of the types. If *classinfo* is not a type or tuple of types and such tuples, a `TypeError` exception is raised. `TypeError` may not be raised for an invalid type if an earlier check succeeds.

*Changed in version 3.10:* *classinfo* can be a [Union Type](#).

`issubclass(class, classinfo)`

Return `True` if *class* is a subclass (direct, indirect, or [virtual](#)) of *classinfo*. A class is considered a subclass of itself. *classinfo* may be a tuple of class objects (or recursively, other such tuples) or a [Union Type](#), in which case return `True` if *class* is a subclass of any entry in *classinfo*. In any other case, a

`TypeError` exception is raised.

*Changed in version 3.10:* `classinfo` can be a [Union Type](#).

`iter(object)`

`iter(object, sentinel)`

Return an [iterator](#) object. The first argument is interpreted very differently depending on the presence of the second argument. Without a second argument, *object* must be a collection object which supports the [iterable](#) protocol (the `__iter__()` method), or it must support the sequence protocol (the `__getitem__()` method with integer arguments starting at 0). If it does not support either of those protocols, `TypeError` is raised. If the second argument, *sentinel*, is given, then *object* must be a callable object. The iterator created in this case will call *object* with no arguments for each call to its `__next__()` method; if the value returned is equal to *sentinel*, `StopIteration` will be raised, otherwise the value will be returned.

See also [Iterator Types](#).

One useful application of the second form of `iter()` is to build a block-reader. For example, reading fixed-width blocks from a binary database file until the end of file is reached:

```
from functools import partial
with open('mydata.db', 'rb') as f:
    for block in iter(partial(f.read, 64), b''):
        process_block(block)
```

`len(s)`

Return the length (the number of items) of an object. The argument may be a sequence (such as a string, bytes, tuple, list, or range) or a collection (such as a dictionary, set, or frozen set).

**CPython implementation detail:** `len` raises `OverflowError` on lengths larger than `sys.maxsize`,

such as `range(2 ** 100)`.

`class list`

`class list(iterable)`

Rather than being a function, `list` is actually a mutable sequence type, as documented in [Lists](#) and [Sequence Types — list, tuple, range](#).

`locals()`

Update and return a dictionary representing the current local symbol table. Free variables are returned by `locals()` when it is called in function blocks, but not in class blocks. Note that at the module level, `locals()` and `globals()` are the same dictionary.

### Note

The contents of this dictionary should not be modified; changes may not affect the values of local and free variables used by the interpreter.

`map(function, iterable, *iterables)`

Return an iterator that applies *function* to every item of *iterable*, yielding the results. If additional *iterables* arguments are passed, *function* must take that many arguments and is applied to the items from all iterables in parallel. With multiple iterables, the iterator stops when the shortest iterable is exhausted. For cases where the function inputs are already arranged into argument tuples, see `itertools.starmap()`.

`max(iterable, *, key=None)`

`max(iterable, *, default=None, key=None)`

`max(arg1, arg2, *args, key=None)`

Return the largest item in an iterable or the largest of two or more arguments.

If one positional argument is provided, it should be an [iterable](#). The largest item in the iterable is returned. If two or more positional arguments are provided, the largest of the positional arguments is returned.

There are two optional keyword-only arguments. The *key* argument specifies a one-argument ordering function like that used for `list.sort()`. The *default* argument specifies an object to return if the provided iterable is empty. If the iterable is empty and *default* is not provided, a [ValueError](#) is raised.

If multiple items are maximal, the function returns the first one encountered. This is consistent with other sort-stability preserving tools such as `sorted(iterable, key=keyfunc, reverse=True)[0]` and `heapq.nlargest(1, iterable, key=keyfunc)`.

*New in version 3.4:* The *default* keyword-only argument.

*Changed in version 3.8:* The *key* can be `None`.

`class memoryview(object)`

Return a “memory view” object created from the given argument. See [Memory Views](#) for more information.

`min(iterable, *, key=None)`

`min(iterable, *, default, key=None)`

`min(arg1, arg2, *args, key=None)`

Return the smallest item in an iterable or the smallest of two or more arguments.

If one positional argument is provided, it should be an [iterable](#). The smallest item in the iterable is returned. If two or more positional arguments are provided, the smallest of the positional arguments is returned.

There are two optional keyword-only arguments. The *key* argument specifies a one-argument ordering function like that

used for `list.sort()`. The *default* argument specifies an object to return if the provided iterable is empty. If the iterable is empty and *default* is not provided, a `ValueError` is raised.

If multiple items are minimal, the function returns the first one encountered. This is consistent with other sort-stability preserving tools such as `sorted(iterable, key=keyfunc)[0]` and `heapq.nsmallest(1, iterable, key=keyfunc)`.

*New in version 3.4:* The *default* keyword-only argument.

*Changed in version 3.8:* The *key* can be `None`.

`next(iterator)`

`next(iterator, default)`

Retrieve the next item from the `iterator` by calling its `__next__()` method. If *default* is given, it is returned if the iterator is exhausted, otherwise `StopIteration` is raised.

*class object*

Return a new featureless object. `object` is a base for all classes. It has methods that are common to all instances of Python classes. This function does not accept any arguments.

### Note

`object` does *not* have a `__dict__`, so you can't assign arbitrary attributes to an instance of the `object` class.

`oct(x)`

Convert an integer number to an octal string prefixed with "0o". The result is a valid Python expression. If *x* is not a Python `int` object, it has to define an `__index__()` method that returns an integer. For example:

```
>>> oct(8)
```

```
'0o10'  
>>> oct(-56)  
'-0o70'
```

If you want to convert an integer number to an octal string either with the prefix “0o” or not, you can use either of the following ways.

```
>>> '%#o' % 10, '%o' % 10  
( '0o12', '12' )  
>>> format(10, '#o'), format(10, 'o')  
( '0o12', '12' )  
>>> f'{10:#o}', f'{10:o}'  
( '0o12', '12' )
```

See also [format\(\)](#) for more information.

`open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True, opener=None)`

Open *file* and return a corresponding [file object](#). If the file cannot be opened, an [OSError](#) is raised. See [Reading and Writing Files](#) for more examples of how to use this function.

*file* is a [path-like object](#) giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed unless *closefd* is set to `False`.)

*mode* is an optional string that specifies the mode in which the file is opened. It defaults to `'r'` which means open for reading in text mode. Other common values are `'w'` for writing (truncating the file if it already exists), `'x'` for exclusive creation, and `'a'` for appending (which on *some* Unix systems, means that *all* writes append to the end of the file regardless of the current seek position). In text mode, if *encoding* is not specified the encoding used is platform-dependent: [locale.getencoding\(\)](#) is called to get the

current locale encoding. (For reading and writing raw bytes use binary mode and leave *encoding* unspecified.) The available modes are:

### **Mode**

---

`r` open for reading (default)

---

`w` open for writing, truncating the file first

---

`x` open for exclusive creation, failing if the file already exists

---

`a` open for writing, appending to the end of file if it exists

---

`b` binary mode

---

`t` text mode (default)

---

`+` open for updating (reading and writing)

---

The default mode is `'r'` (open for reading text, a synonym of `'rt'`). Modes `'w+'` and `'wb'` open and truncate the file. Modes `'r+'` and `'rb'` open the file with no truncation.

As mentioned in the [Overview](#), Python distinguishes between binary and text I/O. Files opened in binary mode (including `'b'` in the *mode* argument) return contents as **bytes** objects without any decoding. In text mode (the default, or when `'t'` is included in the *mode* argument), the contents of the file are returned as **str**, the bytes having been first decoded using a platform-dependent encoding or using the specified *encoding* if given.

### **Note**

Python doesn't depend on the underlying operating system's notion of text files; all the processing is done by Python itself, and is therefore platform-independent.

*buffering* is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable in text mode), and an integer  $> 1$  to indicate the size in bytes of a fixed-size chunk buffer. Note that specifying a buffer size this way applies for binary buffered I/O, but `TextIOWrapper` (i.e.,

files opened with `mode='r+')` would have another buffering. To disable buffering in `TextIOWrapper`, consider using the `write_through` flag for `io.TextIOWrapper.reconfigure()`. When no *buffering* argument is given, the default buffering policy works as follows:

- Binary files are buffered in fixed-size chunks; the size of the buffer is chosen using a heuristic trying to determine the underlying device's "block size" and falling back on `io.DEFAULT_BUFFER_SIZE`. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- "Interactive" text files (files for which `isatty()` returns `True`) use line buffering. Other text files use the policy described above for binary files.

*encoding* is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever `locale.getencoding()` returns), but any *text encoding* supported by Python can be used. See the `codecs` module for the list of supported encodings.

*errors* is an optional string that specifies how encoding and decoding errors are to be handled—this cannot be used in binary mode. A variety of standard error handlers are available (listed under [Error Handlers](#)), though any error handling name that has been registered with `codecs.register_error()` is also valid. The standard names include:

- `'strict'` to raise a `ValueError` exception if there is an encoding error. The default value of `None` has the same effect.
- `'ignore'` ignores errors. Note that ignoring encoding errors can lead to data loss.
- `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data.
- `'surrogateescape'` will represent any incorrect bytes as low surrogate code units ranging from U

+DC80 to U+DCFF. These surrogate code units will then be turned back into the same bytes when the `surrogateescape` error handler is used when writing data. This is useful for processing files in an unknown encoding.

- `'xmlcharrefreplace'` is only supported when writing to a file. Characters not supported by the encoding are replaced with the appropriate XML character reference `&#nnn;`.
- `'backslashreplace'` replaces malformed data by Python's backslashed escape sequences.
- `'namereplace'` (also only supported when writing) replaces unsupported characters with `\N{...}` escape sequences.

*newline* determines how to parse newline characters from the stream. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, universal newlines mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, `os.linesep`. If *newline* is `''` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *closefd* is `False` and a file descriptor rather than a filename was given, the underlying file descriptor will be kept open when the file is closed. If a filename is given *closefd* must be `True` (the default); otherwise, an error will be raised.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*file*, *flags*). *opener* must return an open file descriptor (passing `os.open` as *opener* results in functionality similar to passing `None`).

The newly created file is `non-inheritable`.

The following example uses the `dir_fd` parameter of the `os.open()` function to open a file relative to a given directory:

```
>>> import os
>>> dir_fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
...     return os.open(path, flags, dir_fd=dir_fd)
...
>>> with open('spamspam.txt', 'w', opener=opener) as f:
...     print('This will be written to somedir/spamspam.txt')
...
>>> os.close(dir_fd) # don't leak a file descriptor
```

The type of `file object` returned by the `open()` function depends on the mode. When `open()` is used to open a file in a text mode ('w', 'r', 'wt', 'rt', etc.), it returns a subclass of `io.TextIOBase` (specifically `io.TextIOWrapper`). When used to open a file in a binary mode with buffering, the returned class is a subclass of `io.BufferedIOBase`. The exact class varies: in read binary mode, it returns an `io.BufferedReader`; in write binary and append binary modes, it returns an `io.BufferedWriter`, and in read/write mode, it returns an `io.BufferedRandom`. When buffering is disabled, the raw stream, a subclass of `io.RawIOBase`, `io.FileIO`, is returned.

See also the file handling modules, such as `fileinput`, `io` (where `open()` is declared), `os`, `os.path`, `tempfile`, and `shutil`.

Raises an `auditing event` `open` with arguments `file`, `mode`,

flags.

The `mode` and `flags` arguments may have been modified or inferred from the original call.

*Changed in version 3.3:*

- The `opener` parameter was added.
- The `'x'` mode was added.
- `IOError` used to be raised, it is now an alias of `OSError`.
- `FileExistsError` is now raised if the file opened in exclusive creation mode (`'x'`) already exists.

*Changed in version 3.4:*

- The file is now non-inheritable.

*Changed in version 3.5:*

- If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).
- The `'namereplace'` error handler was added.

*Changed in version 3.6:*

- Support added to accept objects implementing `os.PathLike`.
- On Windows, opening a console buffer may return a subclass of `io.RawIOBase` other than `io.FileIO`.

*Changed in version 3.11:* The `'U'` mode has been removed.

`ord(c)`

Given a string representing one Unicode character, return an integer representing the Unicode code point of that character. For example, `ord('a')` returns the integer 97 and `ord('€')` (Euro sign) returns 8364. This is the inverse of

`chr()`.

`pow(base, exp, mod=None)`

Return *base* to the power *exp*; if *mod* is present, return *base* to the power *exp*, modulo *mod* (computed more efficiently than `pow(base, exp) % mod`). The two-argument form `pow(base, exp)` is equivalent to using the power operator: `base**exp`.

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For `int` operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, `pow(10, 2)` returns 100, but `pow(10, -2)` returns 0.01. For a negative base of type `int` or `float` and a non-integral exponent, a complex result is delivered. For example, `pow(-9, 0.5)` returns a value close to `3j`.

For `int` operands *base* and *exp*, if *mod* is present, *mod* must also be of integer type and *mod* must be nonzero. If *mod* is present and *exp* is negative, *base* must be relatively prime to *mod*. In that case, `pow(inv_base, -exp, mod)` is returned, where *inv\_base* is an inverse to *base* modulo *mod*.

Here's an example of computing an inverse for 38 modulo 97:

```
>>> pow(38, -1, mod=97)
23
>>> 23 * 38 % 97 == 1
True
```

*Changed in version 3.8:* For `int` operands, the three-argument form of `pow` now allows the second argument to be negative, permitting computation of modular inverses.

*Changed in version 3.8:* Allow keyword arguments. Formerly, only positional arguments were supported.

```
print(*objects, sep=' ', end='\n', file=None, flush=False)
```

Print *objects* to the text stream *file*, separated by *sep* and followed by *end*. *sep*, *end*, *file*, and *flush*, if present, must be given as keyword arguments.

All non-keyword arguments are converted to strings like `str()` does and written to the stream, separated by *sep* and followed by *end*. Both *sep* and *end* must be strings; they can also be `None`, which means to use the default values. If no *objects* are given, `print()` will just write *end*.

The *file* argument must be an object with a `write(string)` method; if it is not present or `None`, `sys.stdout` will be used. Since printed arguments are converted to text strings, `print()` cannot be used with binary mode file objects. For these, use `file.write(...)` instead.

Output buffering is usually determined by *file*. However, if *flush* is true, the stream is forcibly flushed.

*Changed in version 3.3:* Added the *flush* keyword argument.

```
class property(fget=None, fset=None, fdel=None, doc=None)
```

Return a property attribute.

*fget* is a function for getting an attribute value. *fset* is a function for setting an attribute value. *fdel* is a function for deleting an attribute value. And *doc* creates a docstring for the attribute.

A typical use is to define a managed attribute `x`:

```
class C:
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
```

```

        self.__x = value

    def delx(self):
        del self.__x

    x = property(getx, setx, delx, "I'm the 'x' pro

```

If *c* is an instance of *C*, *c.x* will invoke the getter, *c.x = value* will invoke the setter, and *del c.x* the deleter.

If given, *doc* will be the docstring of the property attribute. Otherwise, the property will copy *fget*'s docstring (if it exists). This makes it possible to create read-only properties easily using **property()** as a **decorator**:

```

class Parrot:
    def __init__(self):
        self._voltage = 100000

    @property
    def voltage(self):
        """Get the current voltage."""
        return self._voltage

```

The **@property** decorator turns the **voltage()** method into a “getter” for a read-only attribute with the same name, and it sets the docstring for *voltage* to “Get the current voltage.”

A property object has **getter**, **setter**, and **deleter** methods usable as decorators that create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

```

class C:
    def __init__(self):
        self.__x = None

    @property
    def x(self):

```

```

        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x

```

This code is exactly equivalent to the first example. Be sure to give the additional functions the same name as the original property (`x` in this case.)

The returned property object also has the attributes `fget`, `fset`, and `fdel` corresponding to the constructor arguments.

*Changed in version 3.5:* The docstrings of property objects are now writeable.

*class* `range(stop)`

*class* `range(start, stop, step=1)`

Rather than being a function, `range` is actually an immutable sequence type, as documented in [Ranges and Sequence Types — list, tuple, range](#).

*repr(object)*

Return a string containing a printable representation of an object. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to `eval()`; otherwise, the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method. If `sys.displayhook()` is not accessible, this function will raise `RuntimeError`.

`reversed(seq)`

Return a reverse [iterator](#). *seq* must be an object which has a `__reversed__()` method or supports the sequence protocol (the `__len__()` method and the `__getitem__()` method with integer arguments starting at 0).

`round(number, ndigits=None)`

Return *number* rounded to *ndigits* precision after the decimal point. If *ndigits* is omitted or is `None`, it returns the nearest integer to its input.

For the built-in types supporting `round()`, values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done toward the even choice (so, for example, both `round(0.5)` and `round(-0.5)` are 0, and `round(1.5)` is 2). Any integer value is valid for *ndigits* (positive, zero, or negative). The return value is an integer if *ndigits* is omitted or `None`. Otherwise, the return value has the same type as *number*.

For a general Python object *number*, `round` delegates to `number.__round__`.

## Note

The behavior of `round()` for floats can be surprising: for example, `round(2.675, 2)` gives 2.67 instead of the expected 2.68. This is not a bug: it's a result of the fact that most decimal fractions can't be represented exactly as a float. See [Floating Point Arithmetic: Issues and Limitations](#) for more information.

`class set`

`class set(iterable)`

Return a new [set](#) object, optionally with elements taken from *iterable*. `set` is a built-in class. See [set](#) and [Set Types — set, frozenset](#) for documentation about this class.

For other containers see the built-in `frozenset`, `list`, `tuple`, and `dict` classes, as well as the `collections` module.

`setattr(object, name, value)`

This is the counterpart of `getattr()`. The arguments are an object, a string, and an arbitrary value. The string may name an existing attribute or a new attribute. The function assigns the value to the attribute, provided the object allows it. For example, `setattr(x, 'foobar', 123)` is equivalent to `x.foobar = 123`.

*name* need not be a Python identifier as defined in [Identifiers and keywords](#) unless the object chooses to enforce that, for example in a custom `__getattr__()` or via `__slots__`. An attribute whose name is not an identifier will not be accessible using the dot notation, but is accessible through `getattr()` etc..

### Note

Since [private name mangling](#) happens at compilation time, one must manually mangle a private attribute's (attributes with two leading underscores) name in order to set it with `setattr()`.

`class slice(stop)`

`class slice(start, stop, step=1)`

Return a [slice](#) object representing the set of indices specified by `range(start, stop, step)`. The *start* and *step* arguments default to `None`. Slice objects have read-only data attributes `start`, `stop`, and `step` which merely return the argument values (or their default). They have no other explicit functionality; however, they are used by NumPy and other third-party packages. Slice objects are also generated when extended indexing syntax is used. For example: `a[start:stop:step]` or `a[start:stop, i]`. See [itertools.islice\(\)](#) for an alternate version that returns

an iterator.

`sorted(iterable, /, *, key=None, reverse=False)`

Return a new sorted list from the items in *iterable*.

Has two optional arguments which must be specified as keyword arguments.

*key* specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). The default value is `None` (compare the elements directly).

*reverse* is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

Use `functools.cmp_to_key()` to convert an old-style *cmp* function to a *key* function.

The built-in `sorted()` function is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

The sort algorithm uses only `<` comparisons between items. While defining an `__lt__()` method will suffice for sorting, [PEP 8](https://peps.python.org/pep-0008/) [https://peps.python.org/pep-0008/] recommends that all six [rich comparisons](#) be implemented. This will help avoid bugs when using the same data with other ordering tools such as `max()` that rely on a different underlying method. Implementing all six comparisons also helps avoid confusion for mixed type comparisons which can call reflected the `__gt__()` method.

For sorting examples and a brief sorting tutorial, see [Sorting HOW TO](#).

`@staticmethod`

Transform a method into a static method.

A static method does not receive an implicit first argument. To declare a static method, use this idiom:

```
class C:
    @staticmethod
    def f(arg1, arg2, argN): ...
```

The `@staticmethod` form is a function [decorator](#) – see [Function definitions](#) for details.

A static method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). Moreover, they can be called as regular functions (such as `f()`).

Static methods in Python are similar to those found in Java or C++. Also, see [classmethod\(\)](#) for a variant that is useful for creating alternate class constructors.

Like all decorators, it is also possible to call `staticmethod` as a regular function and do something with its result. This is needed in some cases where you need a reference to a function from a class body and you want to avoid the automatic transformation to instance method. For these cases, use this idiom:

```
def regular_function():
    ...

class C:
    method = staticmethod(regular_function)
```

For more information on static methods, see [The standard type hierarchy](#).

*Changed in version 3.10:* Static methods now inherit the method attributes (`__module__`, `__name__`, `__qualname__`, `__doc__` and `__annotations__`), have a new `__wrapped__` attribute, and are now callable as regular functions.

```
class str(object="")
```

`class str(object=b'', encoding='utf-8', errors='strict')`

Return a `str` version of *object*. See `str()` for details.

`str` is the built-in string [class](#). For general information about strings, see [Text Sequence Type — str](#).

`sum(iterable, /, start=0)`

Sums *start* and the items of an *iterable* from left to right and returns the total. The *iterable*'s items are normally numbers, and the start value is not allowed to be a string.

For some use cases, there are good alternatives to `sum()`. The preferred, fast way to concatenate a sequence of strings is by calling `''.join(sequence)`. To add floating point values with extended precision, see `math.fsum()`. To concatenate a series of iterables, consider using `itertools.chain()`.

*Changed in version 3.8:* The *start* parameter can be specified as a keyword argument.

`class super`

`class super(type, object_or_type=None)`

Return a proxy object that delegates method calls to a parent or sibling class of *type*. This is useful for accessing inherited methods that have been overridden in a class.

The *object\_or\_type* determines the [method resolution order](#) to be searched. The search starts from the class right after the *type*.

For example, if `__mro__` of *object\_or\_type* is `D -> B -> C -> A -> object` and the value of *type* is `B`, then `super()` searches `C -> A -> object`.

The `__mro__` attribute of the *object\_or\_type* lists the method resolution search order used by both `getattr()` and `super()`. The attribute is dynamic and can change whenever the inheritance hierarchy is updated.

If the second argument is omitted, the super object returned is unbound. If the second argument is an object, `isinstance(obj, type)` must be true. If the second argument is a type, `issubclass(type2, type)` must be true (this is useful for classmethods).

There are two typical use cases for *super*. In a class hierarchy with single inheritance, *super* can be used to refer to parent classes without naming them explicitly, thus making the code more maintainable. This use closely parallels the use of *super* in other programming languages.

The second use case is to support cooperative multiple inheritance in a dynamic execution environment. This use case is unique to Python and is not found in statically compiled languages or languages that only support single inheritance. This makes it possible to implement “diamond diagrams” where multiple base classes implement the same method. Good design dictates that such implementations have the same calling signature in every case (because the order of calls is determined at runtime, because that order adapts to changes in the class hierarchy, and because that order can include sibling classes that are unknown prior to runtime).

For both use cases, a typical superclass call looks like this:

```
class C(B):
    def method(self, arg):
        super().method(arg)           # This does the same
                                     # super(C, self).met
```

In addition to method lookups, `super()` also works for attribute lookups. One possible use case for this is calling [descriptors](#) in a parent or sibling class.

Note that `super()` is implemented as part of the binding process for explicit dotted attribute lookups such as `super().__getitem__(name)`. It does so by implementing its own `__getattr__()` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, `super()` is undefined for implicit

lookups using statements or operators such as `super()` `[name]`.

Also note that, aside from the zero argument form, `super()` is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references. The zero argument form only works inside a class definition, as the compiler fills in the necessary details to correctly retrieve the class being defined, as well as accessing the current instance for ordinary methods.

For practical suggestions on how to design cooperative classes using `super()`, see [guide to using super\(\)](https://rhettinger.wordpress.com/2011/05/26/super-considered-super/) [https://rhettinger.wordpress.com/2011/05/26/super-considered-super/].

*class tuple*

*class tuple(iterable)*

Rather than being a function, `tuple` is actually an immutable sequence type, as documented in [Tuples](#) and [Sequence Types — list, tuple, range](#).

*class type(object)*

*class type(name, bases, dict, \*\*kws)*

With one argument, return the type of an *object*. The return value is a type object and generally the same object as returned by `object.__class__`.

The `isinstance()` built-in function is recommended for testing the type of an object, because it takes subclasses into account.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute. The *bases* tuple contains the base classes and becomes the `__bases__` attribute; if empty, `object`, the ultimate base of all classes, is added. The *dict* dictionary contains attribute and method definitions for the class body; it may be copied or wrapped before becoming the `__dict__`

attribute. The following two statements create identical `type` objects:

```
>>> class X:
...     a = 1
...
>>> X = type('X', (), dict(a=1))
```

See also [Type Objects](#).

Keyword arguments provided to the three argument form are passed to the appropriate metaclass machinery (usually `__init_subclass__()`) in the same way that keywords in a class definition (besides *metaclass*) would.

See also [Customizing class creation](#).

*Changed in version 3.6:* Subclasses of `type` which don't override `type.__new__` may no longer use the one-argument form to get the type of an object.

`vars()`

`vars(object)`

Return the `__dict__` attribute for a module, class, instance, or any other object with a `__dict__` attribute.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, classes use a `types.MappingProxyType` to prevent direct dictionary updates).

Without an argument, `vars()` acts like `locals()`. Note, the locals dictionary is only useful for reads since updates to the locals dictionary are ignored.

A `TypeError` exception is raised if an object is specified but it doesn't have a `__dict__` attribute (for example, if its class defines the `__slots__` attribute).

`zip(*iterables, strict=False)`

Iterate over several iterables in parallel, producing tuples with an item from each one.

Example:

```
>>> for item in zip([1, 2, 3], ['sugar', 'spice', ''], strict=False):
...     print(item)
...
(1, 'sugar')
(2, 'spice')
(3, 'everything nice')
```

More formally: `zip()` returns an iterator of tuples, where the  $i$ -th tuple contains the  $i$ -th element from each of the argument iterables.

Another way to think of `zip()` is that it turns rows into columns, and columns into rows. This is similar to [transposing a matrix](https://en.wikipedia.org/wiki/Transpose) [https://en.wikipedia.org/wiki/Transpose].

`zip()` is lazy: The elements won't be processed until the iterable is iterated on, e.g. by a `for` loop or by wrapping in a `list`.

One thing to consider is that the iterables passed to `zip()` could have different lengths; sometimes by design, and sometimes because of a bug in the code that prepared these iterables. Python offers three different approaches to dealing with this issue:

- By default, `zip()` stops when the shortest iterable is exhausted. It will ignore the remaining items in the longer iterables, cutting off the result to the length of the shortest iterable:

```
>>> list(zip(range(3), ['fee', 'fi', 'fo', 'fun'], strict=False))
[(0, 'fee'), (1, 'fi'), (2, 'fo')]
```

- `zip()` is often used in cases where the iterables are assumed to be of equal length. In such cases, it's

recommended to use the `strict=True` option. Its output is the same as regular `zip()`:

```
>>> list(zip(('a', 'b', 'c'), (1, 2, 3), strict=True))
[('a', 1), ('b', 2), ('c', 3)]
```

Unlike the default behavior, it raises a `ValueError` if one iterable is exhausted before the others:

```
>>> for item in zip(range(3), ['fee', 'fi', 'fo']):
...     print(item)
...
(0, 'fee')
(1, 'fi')
(2, 'fo')
Traceback (most recent call last):
...
ValueError: zip() argument 2 is longer than argument 1
```

Without the `strict=True` argument, any bug that results in iterables of different lengths will be silenced, possibly manifesting as a hard-to-find bug in another part of the program.

- Shorter iterables can be padded with a constant value to make all the iterables have the same length. This is done by `itertools.zip_longest()`.

Edge cases: With a single iterable argument, `zip()` returns an iterator of 1-tuples. With no arguments, it returns an empty iterator.

Tips and tricks:

- The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using `zip(*(iter(s))*n, strict=True)`. This repeats the *same* iterator *n* times so that each output tuple has the result of *n* calls to the iterator. This has the effect of dividing the input into n-length chunks.

- `zip()` in conjunction with the `*` operator can be used to unzip a list:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> list(zip(x, y))
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zip(x, y))
>>> x == list(x2) and y == list(y2)
True
```

*Changed in version 3.10:* Added the `strict` argument.

`_import_(name, globals=None, locals=None, fromlist=(), level=0)`

### Note

This is an advanced function that is not needed in everyday Python programming, unlike `importlib.import_module()`.

This function is invoked by the `import` statement. It can be replaced (by importing the `builtins` module and assigning to `builtins.__import__`) in order to change semantics of the `import` statement, but doing so is **strongly** discouraged as it is usually simpler to use import hooks (see [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/]) to attain the same goals and does not cause issues with code which assumes the default import implementation is in use. Direct use of `__import__()` is also discouraged in favor of `importlib.import_module()`.

The function imports the module *name*, potentially using the given *globals* and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be imported from the module given by *name*. The standard implementation does not use its *locals* argument at all and uses its *globals* only to determine the package context of the `import` statement.

*level* specifies whether to use absolute or relative imports. 0 (the default) means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling `__import__()` (see [PEP 328](https://peps.python.org/pep-0328/) [https://peps.python.org/pep-0328/] for the details).

When the *name* variable is of the form `package.module`, normally, the top-level package (the name up till the first dot) is returned, *not* the module named by *name*. However, when a non-empty *fromlist* argument is given, the module named by *name* is returned.

For example, the statement `import spam` results in bytecode resembling the following code:

```
spam = __import__('spam', globals(), locals(), [],
```

The statement `import spam.ham` results in this call:

```
spam = __import__('spam.ham', globals(), locals(),
```

Note how `__import__()` returns the toplevel module here because this is the object that is bound to a name by the `import` statement.

On the other hand, the statement `from spam.ham import eggs, sausage as saus` results in

```
_temp = __import__('spam.ham', globals(), locals(),
eggs = _temp.eggs
saus = _temp.sausage
```

Here, the `spam.ham` module is returned from `__import__()`. From this object, the names to import are retrieved and assigned to their respective names.

If you simply want to import a module (potentially within a package) by name, use `importlib.import_module()`.

*Changed in version 3.3:* Negative values for *level* are no longer supported (which also changes the default value to 0).

*Changed in version 3.9:* When the command line options `-E` or `-I` are being used, the environment variable `PYTHONCASEOK` is now ignored.

## Footnotes

1

Note that the parser only accepts the Unix-style end of line convention. If you are reading the code from a file, make sure to use newline conversion mode to convert Windows or Mac-style newlines.

# Built-in Constants

A small number of constants live in the built-in namespace. They are:

## False

The false value of the `bool` type. Assignments to `False` are illegal and raise a `SyntaxError`.

## True

The true value of the `bool` type. Assignments to `True` are illegal and raise a `SyntaxError`.

## None

An object frequently used to represent the absence of a value, as when default arguments are not passed to a function. Assignments to `None` are illegal and raise a `SyntaxError`. `None` is the sole instance of the `NoneType` type.

## NotImplemented

A special value which should be returned by the binary special methods (e.g. `__eq__()`, `__lt__()`, `__add__()`, `__rsub__()`, etc.) to indicate that the operation is not implemented with respect to the other type; may be returned by the in-place binary special methods (e.g. `__imul__()`, `__iand__()`, etc.) for the same purpose. It should not be evaluated in a boolean context. `NotImplemented` is the sole instance of the `types.NotImplementedType` type.

## Note

When a binary (or in-place) method returns `NotImplemented` the interpreter will try the reflected operation on the other type (or some other fallback, depending on the operator). If all attempts return

`NotImplemented`, the interpreter will raise an appropriate exception. Incorrectly returning `NotImplemented` will result in a misleading error message or the `NotImplemented` value being returned to Python code.

See [Implementing the arithmetic operations](#) for examples.

## Note

`NotImplementedError` and `NotImplemented` are not interchangeable, even though they have similar names and purposes. See [NotImplementedError](#) for details on when to use it.

*Changed in version 3.9:* Evaluating `NotImplemented` in a boolean context is deprecated. While it currently evaluates as true, it will emit a [DeprecationWarning](#). It will raise a [TypeError](#) in a future version of Python.

## Ellipsis

The same as the ellipsis literal “...”. Special value used mostly in conjunction with extended slicing syntax for user-defined container data types. `Ellipsis` is the sole instance of the [types.EllipsisType](#) type.

## `__debug__`

This constant is true if Python was not started with an `-O` option. See also the [assert](#) statement.

## Note

The names [None](#), [False](#), [True](#) and `__debug__` cannot be reassigned (assignments to them, even as an attribute name, raise [SyntaxError](#)), so they can be considered “true” constants.

## Constants added by the `site` module

The `site` module (which is imported automatically during startup, except if the `-S` command-line option is given) adds several constants to the built-in namespace. They are useful for the interactive interpreter shell and should not be used in programs.

`quit(code=None)`

`exit(code=None)`

Objects that when printed, print a message like “Use quit() or Ctrl-D (i.e. EOF) to exit”, and when called, raise `SystemExit` with the specified exit code.

`copyright`

`credits`

Objects that when printed or called, print the text of `copyright` or `credits`, respectively.

`license`

Object that when printed, prints the message “Type license() to see the full license text”, and when called, displays the full license text in a pager-like fashion (one screen at a time).

# Built-in Types

The following sections describe the standard types that are built into the interpreter.

The principal built-in types are numerics, sequences, mappings, classes, instances and exceptions.

Some collection classes are mutable. The methods that add, subtract, or rearrange their members in place, and don't return a specific item, never return the collection instance itself but `None`.

Some operations are supported by several object types; in particular, practically all objects can be compared for equality, tested for truth value, and converted to a string (with the `repr()` function or the slightly different `str()` function). The latter function is implicitly used when an object is written by the `print()` function.

## Truth Value Testing

Any object can be tested for truth value, for use in an `if` or `while` condition or as operand of the Boolean operations below.

By default, an object is considered true unless its class defines either a `__bool__()` method that returns `False` or a `__len__()` method that returns zero, when called with the object. <sup>1</sup> Here are most of the built-in objects considered false:

- constants defined to be false: `None` and `False`
- zero of any numeric type: `0`, `0.0`, `0j`, `Decimal(0)`, `Fraction(0, 1)`
- empty sequences and collections: `''`, `()`, `[]`, `{}`, `set()`, `range(0)`

Operations and built-in functions that have a Boolean result always return `0` or `False` for false and `1` or `True` for true, unless otherwise stated. (Important exception: the Boolean operations `or` and `and` always return one of their operands.)

## Boolean Operations — `and`, `or`, `not`

These are the Boolean operations, ordered by ascending priority:

Operation
<del>(1)</del> <code>x or y</code> is true, then <code>x</code> , else <code>y</code>
<del>(2)</del> <code>x and y</code> is false, then <code>x</code> , else <code>y</code>
<del>(3)</del> <code>not x</code> is false, then <code>True</code> , else <code>False</code>

Notes:

1. This is a short-circuit operator, so it only evaluates the second argument if the first one is false.
2. This is a short-circuit operator, so it only evaluates the second argument if the first one is true.
3. `not` has a lower priority than non-Boolean operators, so `not a == b` is interpreted as `not (a == b)`, and `a == not b` is a syntax error.

## Comparisons

There are eight comparison operations in Python. They all have the same priority (which is higher than that of the Boolean operations). Comparisons can be chained arbitrarily; for example, `x < y <= z` is equivalent to `x < y` and `y <= z`, except that `y` is evaluated only once (but in both cases `z` is not evaluated at all when `x < y` is found to be false).

This table summarizes the comparison operations:

Operation
strictly less than
less than or equal
strictly greater than
greater than or equal

`equal`

`not equal`

`object identity`

`negated object identity`

Objects of different types, except different numeric types, never compare equal. The `==` operator is always defined but for some object types (for example, class objects) is equivalent to `is`. The `<`, `<=`, `>` and `>=` operators are only defined where they make sense; for example, they raise a `TypeError` exception when one of the arguments is a complex number.

Non-identical instances of a class normally compare as non-equal unless the class defines the `__eq__()` method.

Instances of a class cannot be ordered with respect to other instances of the same class, or other types of object, unless the class defines enough of the methods `__lt__()`, `__le__()`, `__gt__()`, and `__ge__()` (in general, `__lt__()` and `__eq__()` are sufficient, if you want the conventional meanings of the comparison operators).

The behavior of the `is` and `is not` operators cannot be customized; also they can be applied to any two objects and never raise an exception.

Two more operations with the same syntactic priority, `in` and `not in`, are supported by types that are `iterable` or implement the `__contains__()` method.

## Numeric Types — `int`, `float`, `complex`

There are three distinct numeric types: *integers*, *floating point numbers*, and *complex numbers*. In addition, Booleans are a subtype of integers. Integers have unlimited precision. Floating point numbers are usually implemented using double in C; information about the precision and internal representation of floating point numbers for the machine on which your program is running is available in `sys.float_info`. Complex numbers have a real and imaginary part, which are each a floating point number. To extract

these parts from a complex number `z`, use `z.real` and `z.imag`. (The standard library includes the additional numeric types `fractions.Fraction`, for rationals, and `decimal.Decimal`, for floating-point numbers with user-definable precision.)

Numbers are created by numeric literals or as the result of built-in functions and operators. Unadorned integer literals (including hex, octal and binary numbers) yield integers. Numeric literals containing a decimal point or an exponent sign yield floating point numbers. Appending `'j'` or `'J'` to a numeric literal yields an imaginary number (a complex number with a zero real part) which you can add to an integer or float to get a complex number with real and imaginary parts.

Python fully supports mixed arithmetic: when a binary arithmetic operator has operands of different numeric types, the operand with the “narrower” type is widened to that of the other, where integer is narrower than floating point, which is narrower than complex. A comparison between numbers of different types behaves as though the exact values of those numbers were being compared. [2](#)

The constructors `int()`, `float()`, and `complex()` can be used to produce numbers of a specific type.

All numeric types (except complex) support the following operations (for priorities of the operations, see [Operator precedence](#)):

### Operator notation

`sum` of `x` and `y`

difference of `x` and `y`

product of `x` and `y`

quotient of `x` and `y`

floor quotient of `x` and `y`

remainder of `x / y`

`-x` negated

`x` unchanged

`abs(x)` the value or magnitude of `x`

`int(x)` converted to integer

`float(x)` converted to floating point

`complex(real, imag)` number with real part `re`, imaginary part `im`

defaults to zero.

conjugate of the complex number  $c$

`divmod(x, y)`,  $x \div y$ ,  $x \% y$

the power  $y$

the power  $y$

Notes:

1. Also referred to as integer division. The resultant value is a whole integer, though the result's type is not necessarily `int`. The result is always rounded towards minus infinity:  $1 // 2$  is  $0$ ,  $(-1) // 2$  is  $-1$ ,  $1 // (-2)$  is  $-1$ , and  $(-1) // (-2)$  is  $0$ .
2. Not for complex numbers. Instead convert to floats using `abs()` if appropriate.
3. Conversion from `float` to `int` truncates, discarding the fractional part. See functions `math.floor()` and `math.ceil()` for alternative conversions.
4. float also accepts the strings "nan" and "inf" with an optional prefix "+" or "-" for Not a Number (NaN) and positive or negative infinity.
5. Python defines `pow(0, 0)` and `0 ** 0` to be  $1$ , as is common for programming languages.
6. The numeric literals accepted include the digits  $0$  to  $9$  or any Unicode equivalent (code points with the `Nd` property).

See <https://www.unicode.org/Public/14.0.0/ucd/extracted/DerivedNumericType.txt> for a complete list of code points with the `Nd` property.

All `numbers.Real` types (`int` and `float`) also include the following operations:

### Operations

truncated to `Integral`

rounded to  $n$  digits, rounding half to even. If  $n$  is omitted, it defaults to  $0$ .

the greatest `Integral`  $\leq x$

the least integer  $\geq x$

---

For additional numeric operations see the `math` and `cmath` modules.

## Bitwise Operations on Integer Types

Bitwise operations only make sense for integers. The result of bitwise operations is calculated as though carried out in two's complement with an infinite number of sign bits.

The priorities of the binary bitwise operations are all lower than the numeric operations and higher than the comparisons; the unary operation `~` has the same priority as the other unary numeric operations (`+` and `-`).

This table lists the bitwise operations sorted in ascending priority:

Operation
<code>x &amp; y</code> bitwise <i>and</i> of <i>x</i> and <i>y</i>
<code>x ^ y</code> bitwise <i>exclusive or</i> of <i>x</i> and <i>y</i>
<code>x   y</code> bitwise <i>and</i> of <i>x</i> and <i>y</i>
<code>x &lt;&lt; n</code> shifted left by <i>n</i> bits
<code>x &gt;&gt; n</code> shifted right by <i>n</i> bits
<code>~x</code> the bits of <i>x</i> inverted

Notes:

1. Negative shift counts are illegal and cause a `ValueError` to be raised.
2. A left shift by *n* bits is equivalent to multiplication by `pow(2, n)`.
3. A right shift by *n* bits is equivalent to floor division by `pow(2, n)`.
4. Performing these calculations with at least one extra sign extension bit in a finite two's complement representation (a working bit-width of `1 + max(x.bit_length(), y.bit_length())` or more) is sufficient to get the same result as if there were an infinite number of sign bits.

## Additional Methods on Integer Types

The `int` type implements the `numbers.Integral` abstract base class. In addition, it provides a few more methods:

### `int.bit_length()`

Return the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros:

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

More precisely, if `x` is nonzero, then `x.bit_length()` is the unique positive integer `k` such that  $2^{k-1} \leq \text{abs}(x) < 2^k$ . Equivalently, when `abs(x)` is small enough to have a correctly rounded logarithm, then  $k = 1 + \text{int}(\log(\text{abs}(x), 2))$ . If `x` is zero, then `x.bit_length()` returns 0.

Equivalent to:

```
def bit_length(self):
    s = bin(self)          # binary representation: b
    s = s.lstrip('-0b')    # remove leading zeros and
    return len(s)          # len('100101') --> 6
```

*New in version 3.1.*

### `int.bit_count()`

Return the number of ones in the binary representation of the absolute value of the integer. This is also known as the population count. Example:

```
>>> n = 19
>>> bin(n)
'0b10011'
>>> n.bit_count()
3
>>> (-n).bit_count()
3
```

Equivalent to:

```
def bit_count(self):
    return bin(self).count("1")
```

*New in version 3.10.*

`int.to_bytes(length=1, byteorder='big', *, signed=False)`

Return an array of bytes representing an integer.

```
>>> (1024).to_bytes(2, byteorder='big')
b'\x04\x00'
>>> (1024).to_bytes(10, byteorder='big')
b'\x00\x00\x00\x00\x00\x00\x00\x00\x04\x00'
>>> (-1024).to_bytes(10, byteorder='big', signed=True)
b'\xff\xff\xff\xff\xff\xff\xff\xff\xffc\x00'
>>> x = 1000
>>> x.to_bytes((x.bit_length() + 7) // 8, byteorder='big')
b'\xe8\x03'
```

The integer is represented using *length* bytes, and defaults to 1. An **OverflowError** is raised if the integer is not representable with the given number of bytes.

The *byteorder* argument determines the byte order used to represent the integer, and defaults to "big". If *byteorder* is "big", the most significant byte is at the beginning of the byte array. If *byteorder* is "little", the most significant byte is at the end of the byte array.

The *signed* argument determines whether two's complement is used to represent the integer. If *signed* is `False` and a negative integer is given, an **OverflowError** is raised. The default value for *signed* is `False`.

The default values can be used to conveniently turn an integer into a single byte object:

```
>>> (65).to_bytes()
b'A'
```

However, when using the default arguments, don't try to convert a value greater than 255 or you'll get an [OverflowError](#).

Equivalent to:

```
def to_bytes(n, length=1, byteorder='big', signed=False):
    if byteorder == 'little':
        order = range(length)
    elif byteorder == 'big':
        order = reversed(range(length))
    else:
        raise ValueError("byteorder must be either
                           'big' or 'little'")
    return bytes((n >> i*8) & 0xff for i in order)
```

*New in version 3.2.*

*Changed in version 3.11:* Added default argument values for `length` and `byteorder`.

*classmethod* `int.from_bytes(bytes, byteorder='big', *, signed=False)`

Return the integer represented by the given array of bytes.

```
>>> int.from_bytes(b'\x00\x10', byteorder='big')
16
>>> int.from_bytes(b'\x00\x10', byteorder='little')
4096
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=True)
-1024
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=False)
64512
>>> int.from_bytes([255, 0, 0], byteorder='big')
16711680
```

The argument `bytes` must either be a [bytes-like object](#) or an iterable producing bytes.

The *byteorder* argument determines the byte order used to represent the integer, and defaults to "big". If *byteorder* is "big", the most significant byte is at the beginning of the byte array. If *byteorder* is "little", the most significant byte is at the end of the byte array. To request the native byte order of the host system, use `sys.byteorder` as the byte order value.

The *signed* argument indicates whether two's complement is used to represent the integer.

Equivalent to:

```
def from_bytes(bytes, byteorder='big', signed=False):
    if byteorder == 'little':
        little_ordered = list(bytes)
    elif byteorder == 'big':
        little_ordered = list(reversed(bytes))
    else:
        raise ValueError("byteorder must be either

    n = sum(b << i*8 for i, b in enumerate(little_o
    if signed and little_ordered and (little_order
        n -= 1 << 8*len(little_ordered)

    return n
```

*New in version 3.2.*

*Changed in version 3.11:* Added default argument value for *byteorder*.

`int.as_integer_ratio()`

Return a pair of integers whose ratio is exactly equal to the original integer and with a positive denominator. The integer ratio of integers (whole numbers) is always the integer as the numerator and 1 as the denominator.

*New in version 3.8.*

## Additional Methods on Float

The float type implements the `numbers.Real` abstract base class. float also has the following additional methods.

`float.as_integer_ratio()`

Return a pair of integers whose ratio is exactly equal to the original float and with a positive denominator. Raises `OverflowError` on infinities and a `ValueError` on NaNs.

`float.is_integer()`

Return `True` if the float instance is finite with integral value, and `False` otherwise:

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

Two methods support conversion to and from hexadecimal strings. Since Python's floats are stored internally as binary numbers, converting a float to or from a *decimal* string usually involves a small rounding error. In contrast, hexadecimal strings allow exact representation and specification of floating-point numbers. This can be useful when debugging, and in numerical work.

`float.hex()`

Return a representation of a floating-point number as a hexadecimal string. For finite floating-point numbers, this representation will always include a leading `0x` and a trailing `p` and exponent.

*classmethod* `float.fromhex(s)`

Class method to return the float represented by a hexadecimal string `s`. The string `s` may have leading and trailing whitespace.

Note that `float.hex()` is an instance method, while

`float.fromhex()` is a class method.

A hexadecimal string takes the form:

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

where the optional `sign` may be either `+` or `-`, `integer` and `fraction` are strings of hexadecimal digits, and `exponent` is a decimal integer with an optional leading sign. Case is not significant, and there must be at least one hexadecimal digit in either the integer or the fraction. This syntax is similar to the syntax specified in section 6.4.4.2 of the C99 standard, and also to the syntax used in Java 1.5 onwards. In particular, the output of `float.hex()` is usable as a hexadecimal floating-point literal in C or Java code, and hexadecimal strings produced by C's `%a` format character or Java's `Double.toHexString` are accepted by `float.fromhex()`.

Note that the exponent is written in decimal rather than hexadecimal, and that it gives the power of 2 by which to multiply the coefficient. For example, the hexadecimal string `0x3.a7p10` represents the floating-point number  $(3 + 10./16 + 7./16**2) * 2.0**10$ , or `3740.0`:

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

Applying the reverse conversion to `3740.0` gives a different hexadecimal string representing the same number:

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

## Hashing of numeric types

For numbers `x` and `y`, possibly of different types, it's a requirement that `hash(x) == hash(y)` whenever `x == y` (see the [hash\(\)](#) method documentation for more details). For ease of implementation and efficiency across a variety of numeric types (including `int`, `float`, `decimal.Decimal` and `fractions.Fraction`) Python's hash for numeric types is based

on a single mathematical function that's defined for any rational number, and hence applies to all instances of `int` and `fractions.Fraction`, and all finite instances of `float` and `decimal.Decimal`. Essentially, this function is given by reduction modulo  $P$  for a fixed prime  $P$ . The value of  $P$  is made available to Python as the `modulus` attribute of `sys.hash_info`.

**CPython implementation detail:** Currently, the prime used is  $P = 2^{31} - 1$  on machines with 32-bit C longs and  $P = 2^{61} - 1$  on machines with 64-bit C longs.

Here are the rules in detail:

- If  $x = m / n$  is a nonnegative rational number and  $n$  is not divisible by  $P$ , define `hash(x)` as  $m * \text{invmod}(n, P) \% P$ , where `invmod(n, P)` gives the inverse of  $n$  modulo  $P$ .
- If  $x = m / n$  is a nonnegative rational number and  $n$  is divisible by  $P$  (but  $m$  is not) then  $n$  has no inverse modulo  $P$  and the rule above doesn't apply; in this case define `hash(x)` to be the constant value `sys.hash_info.inf`.
- If  $x = m / n$  is a negative rational number define `hash(x)` as `-hash(-x)`. If the resulting hash is `-1`, replace it with `-2`.
- The particular values `sys.hash_info.inf` and `-sys.hash_info.inf` are used as hash values for positive infinity or negative infinity (respectively).
- For a `complex` number  $z$ , the hash values of the real and imaginary parts are combined by computing `hash(z.real) + sys.hash_info.imag * hash(z.imag)`, reduced modulo  $2^{**}\text{sys.hash_info.width}$  so that it lies in range  $(-2^{**}(\text{sys.hash_info.width} - 1), 2^{**}(\text{sys.hash_info.width} - 1))$ . Again, if the result is `-1`, it's replaced with `-2`.

To clarify the above rules, here's some example Python code, equivalent to the built-in hash, for computing the hash of a rational number, `float`, or `complex`:

```
import sys, math

def hash_fraction(m, n):
```

```
"""Compute the hash of a rational number m / n.
```

```
Assumes m and n are integers, with n positive.  
Equivalent to hash(fractions.Fraction(m, n)).
```

```
"""
```

```
P = sys.hash_info.modulus
```

```
# Remove common factors of P. (Unnecessary if m and n are coprime)
```

```
while m % P == n % P == 0:
```

```
    m, n = m // P, n // P
```

```
if n % P == 0:
```

```
    hash_value = sys.hash_info.inf
```

```
else:
```

```
    # Fermat's Little Theorem: pow(n, P-1, P) is 1,
```

```
    # pow(n, P-2, P) gives the inverse of n modulo P
```

```
    hash_value = (abs(m) % P) * pow(n, P - 2, P) % P
```

```
if m < 0:
```

```
    hash_value = -hash_value
```

```
if hash_value == -1:
```

```
    hash_value = -2
```

```
return hash_value
```

```
def hash_float(x):
```

```
    """Compute the hash of a float x."""
```

```
if math.isnan(x):
```

```
    return object.__hash__(x)
```

```
elif math.isinf(x):
```

```
    return sys.hash_info.inf if x > 0 else -sys.hash_info.inf
```

```
else:
```

```
    return hash_fraction(*x.as_integer_ratio())
```

```
def hash_complex(z):
```

```
    """Compute the hash of a complex number z."""
```

```
hash_value = hash_float(z.real) + sys.hash_info.imag
```

```
# do a signed reduction modulo 2**sys.hash_info.width
```

```
M = 2**(sys.hash_info.width - 1)
hash_value = (hash_value & (M - 1)) - (hash_value &
if hash_value == -1:
    hash_value = -2
return hash_value
```

## Iterator Types

Python supports a concept of iteration over containers. This is implemented using two distinct methods; these are used to allow user-defined classes to support iteration. Sequences, described below in more detail, always support the iteration methods.

One method needs to be defined for container objects to provide [iterable](#) support:

`container.__iter__()`

Return an [iterator](#) object. The object is required to support the iterator protocol described below. If a container supports different types of iteration, additional methods can be provided to specifically request iterators for those iteration types. (An example of an object supporting multiple forms of iteration would be a tree structure which supports both breadth-first and depth-first traversal.) This method corresponds to the [tp\\_iter](#) slot of the type structure for Python objects in the Python/C API.

The iterator objects themselves are required to support the following two methods, which together form the *iterator protocol*:

`iterator.__iter__()`

Return the [iterator](#) object itself. This is required to allow both containers and iterators to be used with the [for](#) and [in](#) statements. This method corresponds to the [tp\\_iter](#) slot of the type structure for Python objects in the Python/C API.

`iterator.__next__()`

Return the next item from the [iterator](#). If there are no further

items, raise the `StopIteration` exception. This method corresponds to the `tp_iternext` slot of the type structure for Python objects in the Python/C API.

Python defines several iterator objects to support iteration over general and specific sequence types, dictionaries, and other more specialized forms. The specific types are not important beyond their implementation of the iterator protocol.

Once an iterator's `__next__()` method raises `StopIteration`, it must continue to do so on subsequent calls. Implementations that do not obey this property are deemed broken.

## Generator Types

Python's `generators` provide a convenient way to implement the iterator protocol. If a container object's `__iter__()` method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and `__next__()` methods. More information about generators can be found in [the documentation for the yield expression](#).

## Sequence Types — `list`, `tuple`, `range`

There are three basic sequence types: lists, tuples, and range objects. Additional sequence types tailored for processing of `binary data` and `text strings` are described in dedicated sections.

## Common Sequence Operations

The operations in the following table are supported by most sequence types, both mutable and immutable. The `collections.abc.Sequence` ABC is provided to make it easier to correctly implement these operations on custom sequence types.

This table lists the sequence operations sorted in ascending priority. In the table, *s* and *t* are sequences of the same type, *n*, *i*, *j* and *k* are integers and *x* is an arbitrary object that meets any type and value restrictions imposed by *s*.

The `in` and `not in` operations have the same priorities as the comparison operations. The `+` (concatenation) and `*` (repetition) operations have the same priority as the corresponding numeric operations. [3](#)

## Repetition

<code>in</code>	True if an item of <code>s</code> is equal to <code>x</code> , else <code>False</code>
<code>not in</code>	True if an item of <code>s</code> is equal to <code>x</code> , else <code>True</code>
<code>+</code>	concatenation of <code>s</code> and <code>t</code>
<code>*</code>	repetition of <code>s</code> <code>n</code> times
<code>len</code>	length of <code>s</code>
<code>min</code>	smallest item of <code>s</code>
<code>max</code>	largest item of <code>s</code>
<code>index</code>	index of the first occurrence of <code>x</code> in <code>s</code> (at or after index <code>i</code> and before index <code>j</code> )
<code>count</code>	total number of occurrences of <code>x</code> in <code>s</code>

Sequences of the same type also support comparisons. In particular, tuples and lists are compared lexicographically by comparing corresponding elements. This means that to compare equal, every element must compare equal and the two sequences must be of the same type and have the same length. (For full details see [Comparisons](#) in the language reference.)

Forward and reversed iterators over mutable sequences access values using an index. That index will continue to march forward (or backward) even if the underlying sequence is mutated. The iterator terminates only when an [IndexError](#) or a [StopIteration](#) is encountered (or when the index drops below zero).

Notes:

1. While the `in` and `not in` operations are used only for simple containment testing in the general case, some specialised sequences (such as [str](#), [bytes](#) and [bytearray](#)) also use them for subsequence testing:

```
>>> "gg" in "eggs"
True
```

2. Values of  $n$  less than 0 are treated as 0 (which yields an empty sequence of the same type as  $s$ ). Note that items in the sequence  $s$  are not copied; they are referenced multiple times. This often haunts new Python programmers; consider:

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

What has happened is that `[]` is a one-element list containing an empty list, so all three elements of `[] * 3` are references to this single empty list. Modifying any of the elements of `lists` modifies this single list. You can create a list of different lists this way:

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

Further explanation is available in the FAQ entry [How do I create a multidimensional list?](#).

3. If  $i$  or  $j$  is negative, the index is relative to the end of sequence  $s$ :  $\text{len}(s) + i$  or  $\text{len}(s) + j$  is substituted. But note that  $-0$  is still  $0$ .
4. The slice of  $s$  from  $i$  to  $j$  is defined as the sequence of items with index  $k$  such that  $i \leq k < j$ . If  $i$  or  $j$  is greater than  $\text{len}(s)$ , use  $\text{len}(s)$ . If  $i$  is omitted or `None`, use  $0$ . If  $j$  is omitted or `None`, use  $\text{len}(s)$ . If  $i$  is greater than or equal to  $j$ , the slice is empty.

5. The slice of `s` from `i` to `j` with step `k` is defined as the sequence of items with index  $x = i + n*k$  such that  $0 \leq n < (j-i)/k$ . In other words, the indices are `i`, `i+k`, `i+2*k`, `i+3*k` and so on, stopping when `j` is reached (but never including `j`). When `k` is positive, `i` and `j` are reduced to `len(s)` if they are greater. When `k` is negative, `i` and `j` are reduced to `len(s) - 1` if they are greater. If `i` or `j` are omitted or `None`, they become “end” values (which end depends on the sign of `k`). Note, `k` cannot be zero. If `k` is `None`, it is treated like `1`.
6. Concatenating immutable sequences always results in a new object. This means that building up a sequence by repeated concatenation will have a quadratic runtime cost in the total sequence length. To get a linear runtime cost, you must switch to one of the alternatives below:
- if concatenating `str` objects, you can build a list and use `str.join()` at the end or else write to an `io.StringIO` instance and retrieve its value when complete
  - if concatenating `bytes` objects, you can similarly use `bytes.join()` or `io.BytesIO`, or you can do in-place concatenation with a `bytearray` object. `bytearray` objects are mutable and have an efficient overallocation mechanism
  - if concatenating `tuple` objects, extend a `list` instead
  - for other types, investigate the relevant class documentation
11. Some sequence types (such as `range`) only support item sequences that follow specific patterns, and hence don't support sequence concatenation or repetition.
12. `index` raises `ValueError` when `x` is not found in `s`. Not all implementations support passing the additional arguments `i` and `j`. These arguments allow efficient searching of subsections of the sequence. Passing the extra arguments is roughly equivalent to using `s[i:j].index(x)`, only without copying any data and with the returned index being relative to the start of the sequence rather than the start of

the slice.

## Immutable Sequence Types

The only operation that immutable sequence types generally implement that is not also implemented by mutable sequence types is support for the `hash()` built-in.

This support allows immutable sequences, such as `tuple` instances, to be used as `dict` keys and stored in `set` and `frozenset` instances.

Attempting to hash an immutable sequence that contains unhashable values will result in `TypeError`.

## Mutable Sequence Types

The operations in the following table are defined on mutable sequence types. The `collections.abc.MutableSequence` ABC is provided to make it easier to correctly implement these operations on custom sequence types.

In the table  $s$  is an instance of a mutable sequence type,  $t$  is any iterable object and  $x$  is an arbitrary object that meets any type and value restrictions imposed by  $s$  (for example, `bytearray` only accepts integers that meet the value restriction  $0 \leq x \leq 255$ ).

### Operation

---

item  $i$  of  $s$  is replaced by  $x$

---

slice of  $s$  from  $i$  to  $j$  is replaced by the contents of the iterable  $t$

---

same as  $s[i:j] = []$

---

the elements of  $s[i:j:k]$  are replaced by those of  $t$

---

removes the elements of  $s[i:j:k]$  from the list

---

appends  $x$  to the end of the sequence (same as

---

$s[\text{len}(s):\text{len}(s)] = [x]$ )

---

(5) moves all items from  $s$  (same as `del s[:]`)

---

(5) creates a shallow copy of  $s$  (same as `s[:]`)

---

extends  $s$  with the contents of  $t$  (for the most part the same as

---

$s[\text{len}(s):\text{len}(s)] = t$ )

---

(6) repeats  $s$  with its contents repeated  $n$  times

---

---

`insert(i, x)` inserts `x` at the index given by `i` (same as `s[i:i] = [x]`)

---

`pop()` removes the item at `i` and also removes it from `s`

---

`pop(i)` removes the item at `i` and also removes it from `s`

---

`remove(x)` removes the first item from `s` where `s[i]` is equal to `x`

---

`reverse()` reverses the items of `s` in place

---

Notes:

1. `t` must have the same length as the slice it is replacing.
2. The optional argument `i` defaults to `-1`, so that by default the last item is removed and returned.
3. `remove()` raises `ValueError` when `x` is not found in `s`.
4. The `reverse()` method modifies the sequence in place for economy of space when reversing a large sequence. To remind users that it operates by side effect, it does not return the reversed sequence.
5. `clear()` and `copy()` are included for consistency with the interfaces of mutable containers that don't support slicing operations (such as `dict` and `set`). `copy()` is not part of the `collections.abc.MutableSequence` ABC, but most concrete mutable sequence classes provide it.

*New in version 3.3:* `clear()` and `copy()` methods.

6. The value `n` is an integer, or an object implementing `__index__()`. Zero and negative values of `n` clear the sequence. Items in the sequence are not copied; they are referenced multiple times, as explained for `s * n` under [Common Sequence Operations](#).

## Lists

Lists are mutable sequences, typically used to store collections of homogeneous items (where the precise degree of similarity will vary by application).

```
class list([iterable])
```

Lists may be constructed in several ways:

- Using a pair of square brackets to denote the empty list:  
`[]`
- Using square brackets, separating items with commas:  
`[a], [a, b, c]`
- Using a list comprehension: `[x for x in iterable]`
- Using the type constructor: `list()` or `list(iterable)`

The constructor builds a list whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a list, a copy is made and returned, similar to `iterable[:]`. For example, `list('abc')` returns `['a', 'b', 'c']` and `list( (1, 2, 3) )` returns `[1, 2, 3]`. If no argument is given, the constructor creates a new empty list, `[]`.

Many other operations also produce lists, including the `sorted()` built-in.

Lists implement all of the **common** and **mutable** sequence operations. Lists also provide the following additional method:

`sort(*, key=None, reverse=False)`

This method sorts the list in place, using only `<` comparisons between items. Exceptions are not suppressed - if any comparison operations fail, the entire sort operation will fail (and the list will likely be left in a partially modified state).

`sort()` accepts two arguments that can only be passed by keyword (**keyword-only arguments**):

*key* specifies a function of one argument that is used to extract a comparison key from each list element (for example, `key=str.lower`). The key corresponding to each item in the list is calculated once and then used for the entire sorting process. The default value of `None` means that list items are sorted directly without

calculating a separate key value.

The `functools.cmp_to_key()` utility is available to convert a 2.x style *cmp* function to a *key* function.

*reverse* is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

This method modifies the sequence in place for economy of space when sorting a large sequence. To remind users that it operates by side effect, it does not return the sorted sequence (use `sorted()` to explicitly request a new sorted list instance).

The `sort()` method is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

For sorting examples and a brief sorting tutorial, see [Sorting HOW TO](#).

**CPython implementation detail:** While a list is being sorted, the effect of attempting to mutate, or even inspect, the list is undefined. The C implementation of Python makes the list appear empty for the duration, and raises `ValueError` if it can detect that the list has been mutated during a sort.

## Tuples

Tuples are immutable sequences, typically used to store collections of heterogeneous data (such as the 2-tuples produced by the `enumerate()` built-in). Tuples are also used for cases where an immutable sequence of homogeneous data is needed (such as allowing storage in a `set` or `dict` instance).

```
class tuple([iterable])
```

Tuples may be constructed in a number of ways:

- Using a pair of parentheses to denote the empty tuple: `()`
- Using a trailing comma for a singleton tuple: `a,` or `(a,)`
- Separating items with commas: `a, b, c` or `(a, b, c)`
- Using the `tuple()` built-in: `tuple()` or `tuple(iterable)`

The constructor builds a tuple whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a tuple, it is returned unchanged. For example, `tuple('abc')` returns `('a', 'b', 'c')` and `tuple([1, 2, 3])` returns `(1, 2, 3)`. If no argument is given, the constructor creates a new empty tuple, `()`.

Note that it is actually the comma which makes a tuple, not the parentheses. The parentheses are optional, except in the empty tuple case, or when they are needed to avoid syntactic ambiguity. For example, `f(a, b, c)` is a function call with three arguments, while `f((a, b, c))` is a function call with a 3-tuple as the sole argument.

Tuples implement all of the `common` sequence operations.

For heterogeneous collections of data where access by name is clearer than access by index, `collections.namedtuple()` may be a more appropriate choice than a simple tuple object.

## Ranges

The `range` type represents an immutable sequence of numbers and is commonly used for looping a specific number of times in `for` loops.

```
class range(stop)
```

`class range(start, stop[, step])`

The arguments to the range constructor must be integers (either built-in `int` or any object that implements the `__index__()` special method). If the `step` argument is omitted, it defaults to 1. If the `start` argument is omitted, it defaults to 0. If `step` is zero, `ValueError` is raised.

For a positive `step`, the contents of a range `r` are determined by the formula `r[i] = start + step*i` where `i >= 0` and `r[i] < stop`.

For a negative `step`, the contents of the range are still determined by the formula `r[i] = start + step*i`, but the constraints are `i >= 0` and `r[i] > stop`.

A range object will be empty if `r[0]` does not meet the value constraint. Ranges do support negative indices, but these are interpreted as indexing from the end of the sequence determined by the positive indices.

Ranges containing absolute values larger than `sys.maxsize` are permitted but some features (such as `len()`) may raise `OverflowError`.

Range examples:

```
>>> list(range(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> list(range(0, 30, 5))
[0, 5, 10, 15, 20, 25]
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
>>> list(range(0, -10, -1))
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> list(range(0))
[]
>>> list(range(1, 0))
[]
```

Range implement all of the [common](#) sequence operations except concatenation and repetition (due to the fact that range objects can only represent sequences that follow a strict pattern and repetition and concatenation will usually violate that pattern).

*start*

The value of the *start* parameter (or 0 if the parameter was not supplied)

*stop*

The value of the *stop* parameter

*step*

The value of the *step* parameter (or 1 if the parameter was not supplied)

The advantage of the [range](#) type over a regular [list](#) or [tuple](#) is that a [range](#) object will always take the same (small) amount of memory, no matter the size of the range it represents (as it only stores the *start*, *stop* and *step* values, calculating individual items and subranges as needed).

Range objects implement the [collections.abc.Sequence](#) ABC, and provide features such as containment tests, element index lookup, slicing and support for negative indices (see [Sequence Types — list, tuple, range](#)):

```
>>> r = range(0, 20, 2)
>>> r
range(0, 20, 2)
>>> 11 in r
False
>>> 10 in r
True
>>> r.index(10)
5
>>> r[5]
10
```

```
>>> r[:5]
range(0, 10, 2)
>>> r[-1]
18
```

Testing range objects for equality with `==` and `!=` compares them as sequences. That is, two range objects are considered equal if they represent the same sequence of values. (Note that two range objects that compare equal might have different **start**, **stop** and **step** attributes, for example `range(0) == range(2, 1, 3)` or `range(0, 3, 2) == range(0, 4, 2)`.)

*Changed in version 3.2:* Implement the Sequence ABC. Support slicing and negative indices. Test **int** objects for membership in constant time instead of iterating through all items.

*Changed in version 3.3:* Define `'=='` and `'!='` to compare range objects based on the sequence of values they define (instead of comparing based on object identity).

*New in version 3.3:* The **start**, **stop** and **step** attributes.

### See also

- The [linspace recipe](https://code.activestate.com/recipes/579000/) [https://code.activestate.com/recipes/579000/] shows how to implement a lazy version of range suitable for floating point applications.

## Text Sequence Type — **str**

Textual data in Python is handled with **str** objects, or *strings*. Strings are immutable [sequences](#) of Unicode code points. String literals are written in a variety of ways:

- Single quotes: `'allows embedded "double" quotes'`
- Double quotes: `"allows embedded 'single' quotes"`
- Triple quoted: `'''Three single quotes'''`, `"""Three double quotes"""`

Triple quoted strings may span multiple lines - all associated whitespace will be included in the string literal.

String literals that are part of a single expression and have only whitespace between them will be implicitly converted to a single string literal. That is, `("spam " "eggs") == "spam eggs"`.

See [String and Bytes literals](#) for more about the various forms of string literal, including supported escape sequences, and the `r` (“raw”) prefix that disables most escape sequence processing.

Strings may also be created from other objects using the `str` constructor.

Since there is no separate “character” type, indexing a string produces strings of length 1. That is, for a non-empty string `s`, `s[0] == s[0:1]`.

There is also no mutable string type, but `str.join()` or `io.StringIO` can be used to efficiently construct strings from multiple fragments.

*Changed in version 3.3:* For backwards compatibility with the Python 2 series, the `u` prefix is once again permitted on string literals. It has no effect on the meaning of string literals and cannot be combined with the `r` prefix.

```
class str(object="")
```

```
class str(object=b'', encoding='utf-8', errors='strict')
```

Return a [string](#) version of *object*. If *object* is not provided, returns the empty string. Otherwise, the behavior of `str()` depends on whether *encoding* or *errors* is given, as follows.

If neither *encoding* nor *errors* is given, `str(object)` returns `type(object).__str__(object)`, which is the “informal” or nicely printable string representation of *object*. For string objects, this is the string itself. If *object* does not have a `__str__()` method, then `str()` falls back to returning `repr(object)`.

If at least one of *encoding* or *errors* is given, *object* should be a

bytes-like object (e.g. `bytes` or `bytearray`). In this case, if object is a `bytes` (or `bytearray`) object, then `str(bytes, encoding, errors)` is equivalent to `bytes.decode(encoding, errors)`. Otherwise, the bytes object underlying the buffer object is obtained before calling `bytes.decode()`. See [Binary Sequence Types — bytes, bytearray, memoryview](#) and [Buffer Protocol](#) for information on buffer objects.

Passing a `bytes` object to `str()` without the *encoding* or *errors* arguments falls under the first case of returning the informal string representation (see also the `-b` command-line option to Python). For example:

```
>>> str(b'Zoot!')
"b'Zoot!'"
```

For more information on the `str` class and its methods, see [Text Sequence Type — str](#) and the [String Methods](#) section below. To output formatted strings, see the [Formatted string literals](#) and [Format String Syntax](#) sections. In addition, see the [Text Processing Services](#) section.

## String Methods

Strings implement all of the [common](#) sequence operations, along with the additional methods described below.

Strings also support two styles of string formatting, one providing a large degree of flexibility and customization (see `str.format()`, [Format String Syntax](#) and [Custom String Formatting](#)) and the other based on C `printf` style formatting that handles a narrower range of types and is slightly harder to use correctly, but is often faster for the cases it can handle ([printf-style String Formatting](#)).

The [Text Processing Services](#) section of the standard library covers a number of other modules that provide various text related utilities (including regular expression support in the `re` module).

`str.capitalize()`

Return a copy of the string with its first character capitalized and the rest lowercased.

*Changed in version 3.8:* The first character is now put into titlecase rather than uppercase. This means that characters like digraphs will only have their first letter capitalized, instead of the full character.

`str.casefold()`

Return a casefolded copy of the string. Casefolded strings may be used for caseless matching.

Casefolding is similar to lowercasing but more aggressive because it is intended to remove all case distinctions in a string. For example, the German lowercase letter 'ß' is equivalent to "ss". Since it is already lowercase, `lower()` would do nothing to 'ß'; `casefold()` converts it to "ss".

The casefolding algorithm is described in section 3.13 of the Unicode Standard.

*New in version 3.3.*

`str.center(width[, fillchar])`

Return centered in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

`str.count(sub[, start[, end]])`

Return the number of non-overlapping occurrences of substring *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

If *sub* is empty, returns the number of empty strings between characters which is the length of the string plus one.

`str.encode(encoding='utf-8', errors='strict')`

Return the string encoded to [bytes](#).

*encoding* defaults to `'utf-8'`; see [Standard Encodings](#) for possible values.

*errors* controls how encoding errors are handled. If `'strict'` (the default), a [UnicodeError](#) exception is raised. Other possible values are `'ignore'`, `'replace'`, `'xmlcharrefreplace'`, `'backslashreplace'` and any other name registered via [codecs.register\\_error\(\)](#). See [Error Handlers](#) for details.

For performance reasons, the value of *errors* is not checked for validity unless an encoding error actually occurs, [Python Development Mode](#) is enabled or a [debug build](#) is used.

*Changed in version 3.1:* Added support for keyword arguments.

*Changed in version 3.9:* The value of the *errors* argument is now checked in [Python Development Mode](#) and in [debug mode](#).

`str.endswith(suffix[, start[, end]])`

Return `True` if the string ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

`str.expandtabs(tabsize=8)`

Return a copy of the string where all tab characters are replaced by one or more spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* characters (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the string, the current column is set to zero and the string is examined character by character. If the character is a tab (`\t`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the character is a newline (`\n`) or return (`\r`), it is copied and the current column is reset to zero. Any other

character is copied unchanged and the current column is incremented by one regardless of how the character is represented when printed.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012      0123      01234 '
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123      01234'
```

`str.find(sub[, start[, end]])`

Return the lowest index in the string where substring *sub* is found within the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

### Note

The `find()` method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> 'Py' in 'Python'
True
```

`str.format(*args, **kwargs)`

Perform a string formatting operation. The string on which this method is called can contain literal text or replacement fields delimited by braces `{}`. Each replacement field contains either the numeric index of a positional argument, or the name of a keyword argument. Returns a copy of the string where each replacement field is replaced with the string value of the corresponding argument.

```
>>> "The sum of 1 + 2 is {0}".format(1+2)
'The sum of 1 + 2 is 3'
```

See [Format String Syntax](#) for a description of the various formatting options that can be specified in format strings.

## Note

When formatting a number (`int`, `float`, `complex`, `decimal.Decimal` and subclasses) with the `n` type (ex: `'{:n}'.format(1234)`), the function temporarily sets the `LC_CTYPE` locale to the `LC_NUMERIC` locale to decode `decimal_point` and `thousands_sep` fields of `localeconv()` if they are non-ASCII or longer than 1 byte, and the `LC_NUMERIC` locale is different than the `LC_CTYPE` locale. This temporary change affects other threads.

*Changed in version 3.7:* When formatting a number with the `n` type, the function sets temporarily the `LC_CTYPE` locale to the `LC_NUMERIC` locale in some cases.

## `str.format_map(mapping)`

Similar to `str.format(**mapping)`, except that `mapping` is used directly and not copied to a `dict`. This is useful if for example `mapping` is a dict subclass:

```
>>> class Default(dict):
...     def __missing__(self, key):
...         return key
...
>>> '{name} was born in {country}'.format_map(Default(
'Guido was born in country'
```

*New in version 3.2.*

## `str.index(sub[, start[, end]])`

Like `find()`, but raise `ValueError` when the substring is not found.

## `str.isalnum()`

Return `True` if all characters in the string are alphanumeric and there is at least one character, `False` otherwise. A character `c` is alphanumeric if one of the following returns

`True: c.isalpha(), c.isdecimal(), c.isdigit(), or c.isnumeric()`.

### `str.isalpha()`

Return `True` if all characters in the string are alphabetic and there is at least one character, `False` otherwise. Alphabetic characters are those characters defined in the Unicode character database as “Letter”, i.e., those with general category property being one of “Lm”, “Lt”, “Lu”, “Ll”, or “Lo”. Note that this is different from the “Alphabetic” property defined in the Unicode Standard.

### `str.isascii()`

Return `True` if the string is empty or all characters in the string are ASCII, `False` otherwise. ASCII characters have code points in the range U+0000-U+007F.

*New in version 3.7.*

### `str.isdecimal()`

Return `True` if all characters in the string are decimal characters and there is at least one character, `False` otherwise. Decimal characters are those that can be used to form numbers in base 10, e.g. U+0660, ARABIC-INDIC DIGIT ZERO. Formally a decimal character is a character in the Unicode General Category “Nd”.

### `str.isdigit()`

Return `True` if all characters in the string are digits and there is at least one character, `False` otherwise. Digits include decimal characters and digits that need special handling, such as the compatibility superscript digits. This covers digits which cannot be used to form numbers in base 10, like the Kharosthi numbers. Formally, a digit is a character that has the property value `Numeric_Type = Digit` or `Numeric_Type = Decimal`.

### `str.isidentifier()`

Return `True` if the string is a valid identifier according to the language definition, section [Identifiers and keywords](#).

Call `keyword.iskeyword()` to test whether string `s` is a reserved identifier, such as `def` and `class`.

Example:

```
>>> from keyword import iskeyword

>>> 'hello'.isidentifier(), iskeyword('hello')
(True, False)
>>> 'def'.isidentifier(), iskeyword('def')
(True, True)
```

`str.islower()`

Return `True` if all cased characters [4](#) in the string are lowercase and there is at least one cased character, `False` otherwise.

`str.isnumeric()`

Return `True` if all characters in the string are numeric characters, and there is at least one character, `False` otherwise. Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH. Formally, numeric characters are those with the property value `Numeric_Type=Digit`, `Numeric_Type=Decimal` or `Numeric_Type=Numeric`.

`str.isprintable()`

Return `True` if all characters in the string are printable or the string is empty, `False` otherwise. Nonprintable characters are those characters defined in the Unicode character database as “Other” or “Separator”, excepting the ASCII space (0x20) which is considered printable. (Note that printable characters in this context are those which should not be escaped when `repr()` is invoked on a string. It has no bearing on the handling of strings written to

`sys.stdout` or `sys.stderr`.)

`str.isspace()`

Return `True` if there are only whitespace characters in the string and there is at least one character, `False` otherwise.

A character is *whitespace* if in the Unicode character database (see [unicodedata](#)), either its general category is `Zs` (“Separator, space”), or its bidirectional class is one of `WS`, `B`, or `S`.

`str.istitle()`

Return `True` if the string is a titlecased string and there is at least one character, for example uppercase characters may only follow uncased characters and lowercase characters only cased ones. Return `False` otherwise.

`str.isupper()`

Return `True` if all cased characters [4](#) in the string are uppercase and there is at least one cased character, `False` otherwise.

```
>>> 'BANANA'.isupper()
True
>>> 'banana'.isupper()
False
>>> 'baNana'.isupper()
False
>>> ' '.isupper()
False
```

`str.join(iterable)`

Return a string which is the concatenation of the strings in *iterable*. A `TypeError` will be raised if there are any non-string values in *iterable*, including `bytes` objects. The separator between elements is the string providing this method.

`str.ljust(width[, fillchar])`

Return the string left justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

`str.lower()`

Return a copy of the string with all the cased characters [4](#) converted to lowercase.

The lowercasing algorithm used is described in section 3.13 of the Unicode Standard.

`str.lstrip([chars])`

Return a copy of the string with leading characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.lstrip()
'spacious'
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

See [`str.removeprefix\(\)`](#) for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> 'Arthur: three!'.lstrip('Arthur: ')
'ee!'
>>> 'Arthur: three!'.removeprefix('Arthur: ')
'three!'
```

`static str.maketrans(x[, y[, z]])`

This static method returns a translation table usable for [`str.translate\(\)`](#).

If there is only one argument, it must be a dictionary mapping Unicode ordinals (integers) or characters (strings of length 1) to Unicode ordinals, strings (of arbitrary lengths) or `None`. Character keys will then be converted to ordinals.

If there are two arguments, they must be strings of equal length, and in the resulting dictionary, each character in `x` will be mapped to the character at the same position in `y`. If there is a third argument, it must be a string, whose characters will be mapped to `None` in the result.

### `str.partition(sep)`

Split the string at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing the string itself, followed by two empty strings.

### `str.removeprefix(prefix, /)`

If the string starts with the *prefix* string, return `string[len(prefix):]`. Otherwise, return a copy of the original string:

```
>>> 'TestHook'.removeprefix('Test')
'Hook'
>>> 'BaseTestCase'.removeprefix('Test')
'BaseTestCase'
```

*New in version 3.9.*

### `str.removesuffix(suffix, /)`

If the string ends with the *suffix* string and that *suffix* is not empty, return `string[:-len(suffix)]`. Otherwise, return a copy of the original string:

```
>>> 'MiscTests'.removesuffix('Tests')
'Misc'
>>> 'TmpDirMixin'.removesuffix('Tests')
'TmpDirMixin'
```

*New in version 3.9.*

`str.replace(old, new[, count])`

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

`str.rfind(sub[, start[, end]])`

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

`str.rindex(sub[, start[, end]])`

Like `rfind()` but raises `ValueError` when the substring *sub* is not found.

`str.rjust(width[, fillchar])`

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

`str.rpartition(sep)`

Split the string at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty strings, followed by the string itself.

`str.rsplit(sep=None, maxsplit=-1)`

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any whitespace string is a separator. Except for splitting from the right, `rsplit()` behaves like `split()` which is described

in detail below.

`str.rstrip([chars])`

Return a copy of the string with trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

See [`str.removesuffix\(\)`](#) for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> 'Monty Python'.rstrip(' Python')
'M'
>>> 'Monty Python'.removesuffix(' Python')
'Monty'
```

`str.split(sep=None, maxsplit=-1)`

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done (thus, the list will have at most *maxsplit*+1 elements). If *maxsplit* is not specified or `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty strings (for example, `'1,,2'.split(',')` returns `['1', '', '2']`). The *sep* argument may consist of multiple characters (for example, `'1<>2<>3'.split('<>')` returns `['1', '2', '3']`). Splitting an empty string with a specified separator returns `['']`.

For example:

```
>>> '1,2,3'.split(',')
['1', '2', '3']
>>> '1,2,3'.split(',', maxsplit=1)
['1', '2,3']
>>> '1,2,,3,.'.split(',')
['1', '2', '', '3', '']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the string has leading or trailing whitespace. Consequently, splitting an empty string or a string consisting of just whitespace with a `None` separator returns `[]`.

For example:

```
>>> '1 2 3'.split()
['1', '2', '3']
>>> '1 2 3'.split(maxsplit=1)
['1', '2 3']
>>> ' 1 2 3 '.split()
['1', '2', '3']
```

`str.splitlines(keepends = False)`

Return a list of the lines in the string, breaking at line boundaries. Line breaks are not included in the resulting list unless *keepends* is given and true.

This method splits on the following line boundaries. In particular, the boundaries are a superset of [universal newlines](#).

### Representation

---

Line Feed

---

Carriage Return

---

Carriage Return + Line Feed

---

Line Tabulation

---

Form Feed

---

File Separator

---

Group Separator
Record Separator
NextLine (C1 Control Code)
Line Separator
Paragraph Separator

*Changed in version 3.2:* `\v` and `\f` added to list of line boundaries.

For example:

```
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

Unlike `split()` when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

For comparison, `split('\n')` gives:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

`str.startswith(prefix[, start, end])`

Return `True` if string starts with the *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test string beginning at that position. With optional *end*, stop comparing string at that position.

`str.strip([chars])`

Return a copy of the string with the leading and trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

The outermost leading and trailing *chars* argument values are stripped from the string. Characters are removed from the leading end until reaching a string character that is not contained in the set of characters in *chars*. A similar action takes place on the trailing end. For example:

```
>>> comment_string = '#..... Section 3.2.1 Issue
>>> comment_string.strip('.#! ')
'Section 3.2.1 Issue #32'
```

## `str.swapcase()`

Return a copy of the string with uppercase characters converted to lowercase and vice versa. Note that it is not necessarily true that `s.swapcase().swapcase() == s`.

## `str.title()`

Return a titlecased version of the string where words start with an uppercase character and the remaining characters are lowercase.

For example:

```
>>> 'Hello world'.title()
'Hello World'
```

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition

works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> "they're bill's friends from the UK".title()
'They'Re Bill'S Friends From The Uk'
```

The `string.capwords()` function does not have this problem, as it splits words on spaces only.

Alternatively, a workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+('[A-Za-z]+)?",
...                   lambda mo: mo.group(0).capitalize(),
...                   s)
...
>>> titlecase("they're bill's friends.")
'They're Bill's Friends.'
```

## `str.translate(table)`

Return a copy of the string in which each character has been mapped through the given translation table. The table must be an object that implements indexing via `__getitem__()`, typically a [mapping](#) or [sequence](#). When indexed by a Unicode ordinal (an integer), the table object can do any of the following: return a Unicode ordinal or a string, to map the character to one or more other characters; return `None`, to delete the character from the return string; or raise a [LookupError](#) exception, to map the character to itself.

You can use `str.maketrans()` to create a translation map from character-to-character mappings in different formats.

See also the [codecs](#) module for a more flexible approach to custom character mappings.

## `str.upper()`

Return a copy of the string with all the cased characters [4](#) converted to uppercase. Note that `s.upper().isupper()` might be `False` if `s` contains uncased characters or if the Unicode category of the resulting character(s) is not “Lu” (Letter, uppercase), but e.g. “Lt” (Letter, titlecase).

The uppercasing algorithm used is described in section 3.13 of the Unicode Standard.

`str.zfill(width)`

Return a copy of the string left filled with ASCII ‘0’ digits to make a string of length *width*. A leading sign prefix (‘+’/‘-’) is handled by inserting the padding *after* the sign character rather than before. The original string is returned if *width* is less than or equal to `len(s)`.

For example:

```
>>> "42".zfill(5)
'00042'
>>> "-42".zfill(5)
'-0042'
```

## printf-style String Formatting

### Note

The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). Using the newer [formatted string literals](#), the `str.format()` interface, or [template strings](#) may help avoid these errors. Each of these alternatives provides their own trade-offs and benefits of simplicity, flexibility, and/or extensibility.

String objects have one unique built-in operation: the `%` operator (modulo). This is also known as the string *formatting* or *interpolation* operator. Given `format % values` (where *format* is a string), `%` conversion specifications in *format* are replaced with zero or more

elements of *values*. The effect is similar to using the `sprintf()` in the C language.

If *format* requires a single argument, *values* may be a single non-tuple object. <sup>5</sup> Otherwise, *values* must be a tuple with exactly the number of items specified by the format string, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the string *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print('%(language)s has %(number)03d quote types.' %  
...       {'language': "Python", "number": 2})  
Python has 002 quote types.
```

In this case no `*` specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

---

## Flagging

The value conversion will use the “alternate form” (where defined below).

The conversion will be zero padded for numeric values.

The converted value is left adjusted (overrides the '0' conversion if both are given).

(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.

A sign character ('+' or '-') will precede the conversion (overrides a “space” flag).

A length modifier (h, l, or L) may be present, but is ignored as it is not necessary for Python – so e.g. %ld is identical to %d.

The conversion types are:

## Notation

Signed integer decimal.

Signed integer decimal.

Signed octal value.

Obsolete type – it is identical to 'd'.

Signed hexadecimal (lowercase).

Signed hexadecimal (uppercase).

Floating point exponential format (lowercase).

Floating point exponential format (uppercase).

Floating point decimal format.

Floating point decimal format.

Floating point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.

Floating point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.

Single character (accepts integer or single character string).

Formatting (converts any Python object using `repr()`).

Formatting (converts any Python object using `str()`).

Formatting (converts any Python object using `ascii()`).

No argument is converted, results in a '%' character in the result.

Notes:

1. The alternate form causes a leading octal specifier ('0o') to be inserted before the first digit.
2. The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.
3. The alternate form causes the result to always contain a decimal point, even if no digits follow it.

The precision determines the number of digits after the decimal point and defaults to 6.

4. The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

5. If precision is *N*, the output is truncated to *N* characters.
6. See [PEP 237](https://peps.python.org/pep-0237/) [https://peps.python.org/pep-0237/].

Since Python strings have an explicit length, `%s` conversions do not assume that `'\0'` is the end of the string.

*Changed in version 3.1:* `%f` conversions for numbers whose absolute value is over `1e50` are no longer replaced by `%g` conversions.

## Binary Sequence Types — `bytes`, `bytearray`, `memoryview`

The core built-in types for manipulating binary data are `bytes` and `bytearray`. They are supported by `memoryview` which uses the [buffer protocol](#) to access the memory of other binary objects without needing to make a copy.

The `array` module supports efficient storage of basic data types like 32-bit integers and IEEE754 double-precision floating values.

## Bytes Objects

Bytes objects are immutable sequences of single bytes. Since many major binary protocols are based on the ASCII text encoding, bytes objects offer several methods that are only valid when working with ASCII compatible data and are closely related to string objects in a variety of other ways.

`class bytes([source[, encoding[, errors]]])`

Firstly, the syntax for bytes literals is largely the same as that for string literals, except that a `b` prefix is added:

- Single quotes: `b'still allows embedded "double" quotes'`
- Double quotes: `b"still allows embedded 'single' quotes"`
- Triple quoted: `b'''3 single quotes'''`, `b"""3 double quotes"""`

Only ASCII characters are permitted in bytes literals (regardless of the declared source code encoding). Any binary values over 127 must be entered into bytes literals using the appropriate escape sequence.

As with string literals, bytes literals may also use a `r` prefix to disable processing of escape sequences. See [String and Bytes literals](#) for more about the various forms of bytes literal, including supported escape sequences.

While bytes literals and representations are based on ASCII text, bytes objects actually behave like immutable sequences of integers, with each value in the sequence restricted such that  $0 \leq x < 256$  (attempts to violate this restriction will trigger `ValueError`). This is done deliberately to emphasise that while many binary formats include ASCII based elements and can be usefully manipulated with some text-oriented algorithms, this is not generally the case for arbitrary binary data (blindly applying text processing algorithms to binary data formats that are not ASCII compatible will usually lead to data corruption).

In addition to the literal forms, bytes objects can be created in a number of other ways:

- A zero-filled bytes object of a specified length:  
`bytes(10)`
- From an iterable of integers: `bytes(range(20))`
- Copying existing binary data via the buffer protocol:  
`bytes(obj)`

Also see the [bytes](#) built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytes type has an additional class method to read data in that format:

*classmethod* `fromhex(string)`

This [bytes](#) class method returns a bytes object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytes.fromhex('2Ef0 F1f2  ')
b'\xf0\xf1\xf2'
```

*Changed in version 3.7:* [bytes.fromhex\(\)](#) now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytes object into its hexadecimal representation.

`hex([sep[, bytes_per_sep]])`

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> b'\xf0\xf1\xf2'.hex()
'f0f1f2'
```

If you want to make the hex string easier to read, you can specify a single character separator *sep* parameter

to include in the output. By default, this separator will be included between each byte. A second optional *bytes\_per\_sep* parameter controls the spacing. Positive values calculate the separator position from the right, negative values from the left.

```
>>> value = b'\xf0\xf1\xf2'
>>> value.hex('-')
'f0-f1-f2'
>>> value.hex('_', 2)
'f0_f1f2'
>>> b'UUDDLRLRAB'.hex(' ', -4)
'55554444 4c524c52 4142'
```

*New in version 3.5.*

*Changed in version 3.8:* `bytes.hex()` now supports optional *sep* and *bytes\_per\_sep* parameters to insert separators between bytes in the hex output.

Since bytes objects are sequences of integers (akin to a tuple), for a bytes object *b*, `b[0]` will be an integer, while `b[0:1]` will be a bytes object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytes objects uses the literal format (`b'...'`) since it is often more useful than e.g. `bytes([46, 46, 46])`. You can always convert a bytes object into a list of integers using `list(b)`.

## Bytearray Objects

**bytearray** objects are a mutable counterpart to **bytes** objects.

```
class bytearray([source[, encoding[, errors]]])
```

There is no dedicated literal syntax for bytearray objects, instead they are always created by calling the constructor:

- Creating an empty instance: `bytearray()`
- Creating a zero-filled instance with a given length:

- ```
bytearray(10)
```
- From an iterable of integers:  
`bytearray(range(20))`
  - Copying existing binary data via the buffer protocol:  
`bytearray(b'Hi!')`

As bytearray objects are mutable, they support the [mutable](#) sequence operations in addition to the common bytes and bytearray operations described in [Bytes and Bytearray Operations](#).

Also see the [bytearray](#) built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytearray type has an additional class method to read data in that format:

*classmethod* `fromhex(string)`

This [bytearray](#) class method returns bytearray object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytearray.fromhex('2Ef0 F1f2  ')\nbytearray(b'\\xf0\\xf1\\xf2')
```

*Changed in version 3.7:* [bytearray.fromhex\(\)](#) now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytearray object into its hexadecimal representation.

`hex([sep[, bytes_per_sep]])`

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> bytearray(b'\\xf0\\xf1\\xf2').hex()\n'f0f1f2'
```

*New in version 3.5.*

*Changed in version 3.8:* Similar to `bytes.hex()`, `bytearray.hex()` now supports optional `sep` and `bytes_per_sep` parameters to insert separators between bytes in the hex output.

Since bytearray objects are sequences of integers (akin to a list), for a bytearray object `b`, `b[0]` will be an integer, while `b[0:1]` will be a bytearray object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytearray objects uses the bytes literal format (`bytearray(b'...')`) since it is often more useful than e.g. `bytearray([46, 46, 46])`. You can always convert a bytearray object into a list of integers using `list(b)`.

## Bytes and Bytearray Operations

Both bytes and bytearray objects support the [common](#) sequence operations. They interoperate not just with operands of the same type, but with any [bytes-like object](#). Due to this flexibility, they can be freely mixed in operations without causing errors. However, the return type of the result may depend on the order of operands.

### Note

The methods on bytes and bytearray objects don't accept strings as their arguments, just as the methods on strings don't accept bytes as their arguments. For example, you have to write:

```
a = "abc"
b = a.replace("a", "f")
```

and:

```
a = b"abc"
b = a.replace(b"a", b"f")
```

Some bytes and bytearray operations assume the use of ASCII

compatible binary formats, and hence should be avoided when working with arbitrary binary data. These restrictions are covered below.

## Note

Using these ASCII based operations to manipulate binary data that is not stored in an ASCII based format may lead to data corruption.

The following methods on bytes and bytearray objects can be used with arbitrary binary data.

`bytes.count(sub[, start[, end]])`

`bytearray.count(sub[, start[, end]])`

Return the number of non-overlapping occurrences of subsequence *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

The subsequence to search for may be any [bytes-like object](#) or an integer in the range 0 to 255.

If *sub* is empty, returns the number of empty slices between characters which is the length of the bytes object plus one.

*Changed in version 3.3:* Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.removeprefix(prefix, /)`

`bytearray.removeprefix(prefix, /)`

If the binary data starts with the *prefix* string, return `bytes[len(prefix) :]`. Otherwise, return a copy of the original binary data:

```
>>> b'TestHook'.removeprefix(b'Test')
b'Hook'
>>> b'BaseTestCase'.removeprefix(b'Test')
b'BaseTestCase'
```

The *prefix* may be any [bytes-like object](#).

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

*New in version 3.9.*

```
bytes.removesuffix(suffix, /)
```

```
bytearray.removesuffix(suffix, /)
```

If the binary data ends with the *suffix* string and that *suffix* is not empty, return `bytes[:-len(suffix)]`. Otherwise, return a copy of the original binary data:

```
>>> b'MiscTests'.removesuffix(b'Tests')
b'Misc'
>>> b'TmpDirMixin'.removesuffix(b'Tests')
b'TmpDirMixin'
```

The *suffix* may be any [bytes-like object](#).

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

*New in version 3.9.*

```
bytes.decode(encoding='utf-8', errors='strict')
```

```
bytearray.decode(encoding='utf-8', errors='strict')
```

Return the bytes decoded to a [str](#).

*encoding* defaults to `'utf-8'`; see [Standard Encodings](#) for possible values.

*errors* controls how decoding errors are handled. If

'strict' (the default), a [UnicodeError](#) exception is raised. Other possible values are 'ignore', 'replace', and any other name registered via [codecs.register\\_error\(\)](#). See [Error Handlers](#) for details.

For performance reasons, the value of *errors* is not checked for validity unless a decoding error actually occurs, [Python Development Mode](#) is enabled or a [debug build](#) is used.

### Note

Passing the *encoding* argument to [str](#) allows decoding any [bytes-like object](#) directly, without needing to make a temporary [bytes](#) or [bytearray](#) object.

*Changed in version 3.1:* Added support for keyword arguments.

*Changed in version 3.9:* The value of the *errors* argument is now checked in [Python Development Mode](#) and in [debug mode](#).

`bytes.endswith(suffix[, start[, end]])`

`bytearray.endswith(suffix[, start[, end]])`

Return `True` if the binary data ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The suffix(es) to search for may be any [bytes-like object](#).

`bytes.find(sub[, start[, end]])`

`bytearray.find(sub[, start[, end]])`

Return the lowest index in the data where the subsequence *sub* is found, such that *sub* is contained in the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

The subsequence to search for may be any [bytes-like object](#) or

an integer in the range 0 to 255.

### Note

The `find()` method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> b'Py' in b'Python'
True
```

*Changed in version 3.3:* Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.index(sub[, start[, end]])`

`bytearray.index(sub[, start[, end]])`

Like `find()`, but raise `ValueError` when the subsequence is not found.

The subsequence to search for may be any [bytes-like object](#) or an integer in the range 0 to 255.

*Changed in version 3.3:* Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.join(iterable)`

`bytearray.join(iterable)`

Return a bytes or bytearray object which is the concatenation of the binary data sequences in *iterable*. A `TypeError` will be raised if there are any values in *iterable* that are not [bytes-like objects](#), including `str` objects. The separator between elements is the contents of the bytes or bytearray object providing this method.

*static* `bytes.maketrans(from, to)`

*static* `bytearray.maketrans(from, to)`

This static method returns a translation table usable for `bytes.translate()` that will map each character in *from*

into the character at the same position in *to*; *from* and *to* must both be [bytes-like objects](#) and have the same length.

*New in version 3.1.*

`bytes.partition(sep)`

`bytearray.partition(sep)`

Split the sequence at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing a copy of the original sequence, followed by two empty bytes or bytearray objects.

The separator to search for may be any [bytes-like object](#).

`bytes.replace(old, new[, count])`

`bytearray.replace(old, new[, count])`

Return a copy of the sequence with all occurrences of subsequence *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

The subsequence to search for and its replacement may be any [bytes-like object](#).

### **Note**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.rfind(sub[, start[, end]])`

`bytearray.rfind(sub[, start[, end]])`

Return the highest index in the sequence where the subsequence *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

The subsequence to search for may be any [bytes-like object](#) or an integer in the range 0 to 255.

*Changed in version 3.3:* Also accept an integer in the range 0 to 255 as the subsequence.

```
bytes.rindex(sub[, start[, end]])  
bytearray.rindex(sub[, start[, end]])
```

Like [rfind\(\)](#) but raises [ValueError](#) when the subsequence *sub* is not found.

The subsequence to search for may be any [bytes-like object](#) or an integer in the range 0 to 255.

*Changed in version 3.3:* Also accept an integer in the range 0 to 255 as the subsequence.

```
bytes.rpartition(sep)  
bytearray.rpartition(sep)
```

Split the sequence at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty bytes or bytearray objects, followed by a copy of the original sequence.

The separator to search for may be any [bytes-like object](#).

```
bytes.startswith(prefix[, start[, end]])  
bytearray.startswith(prefix[, start[, end]])
```

Return `True` if the binary data starts with the specified *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The prefix(es) to search for may be any [bytes-like object](#).

```
bytes.translate(table, /, delete=b'')
```

`bytearray.translate(table, /, delete=b'')`

Return a copy of the bytes or bytearray object where all bytes occurring in the optional argument *delete* are removed, and the remaining bytes have been mapped through the given translation table, which must be a bytes object of length 256.

You can use the `bytes.maketrans()` method to create a translation table.

Set the *table* argument to `None` for translations that only delete characters:

```
>>> b'read this short text'.translate(None, b'aeiou')
b'rd ths shrt txt'
```

*Changed in version 3.6:* *delete* is now supported as a keyword argument.

The following methods on bytes and bytearray objects have default behaviours that assume the use of ASCII compatible binary formats, but can still be used with arbitrary binary data by passing appropriate arguments. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

`bytes.center(width[, fillbyte])`

`bytearray.center(width[, fillbyte])`

Return a copy of the object centered in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For `bytes` objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

```
bytes.ljust(width[, fillbyte])
```

```
bytearray.ljust(width[, fillbyte])
```

Return a copy of the object left justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For **bytes** objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

```
bytes.lstrip([chars])
```

```
bytearray.lstrip([chars])
```

Return a copy of the sequence with specified leading bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> b'    spacious    '.lstrip()
b'spacious    '
>>> b'www.example.com'.lstrip(b'cmowz.')
b'example.com'
```

The binary sequence of byte values to remove may be any **bytes-like object**. See **`removeprefix()`** for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> b'Arthur: three!'.lstrip(b'Arthur: ')
b'ee!'
>>> b'Arthur: three!'.removeprefix(b'Arthur: ')
b'three!'
```

## Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

```
bytes.rjust(width[, fillbyte])
```

```
bytearray.rjust(width[, fillbyte])
```

Return a copy of the object right justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For **bytes** objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

## Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

```
bytes.rsplit(sep=None, maxsplit=-1)
```

```
bytearray.rsplit(sep=None, maxsplit=-1)
```

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any subsequence consisting solely of ASCII whitespace is a separator. Except for splitting from the right, **rsplit()** behaves like **split()** which is described in detail below.

```
bytes.rstrip([chars])
```

```
bytearray.rstrip([chars])
```

Return a copy of the sequence with specified trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If

omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.rstrip()
b'   spacious'
>>> b'mississippi'.rstrip(b'ipz')
b'mississ'
```

The binary sequence of byte values to remove may be any [bytes-like object](#). See [removesuffix\(\)](#) for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> b'Monty Python'.rstrip(b' Python')
b'M'
>>> b'Monty Python'.removesuffix(b' Python')
b'Monty'
```

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.split(sep=None, maxsplit=-1)`

`bytearray.split(sep=None, maxsplit=-1)`

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given and non-negative, at most *maxsplit* splits are done (thus, the list will have at most *maxsplit*+1 elements). If *maxsplit* is not specified or is `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty subsequences (for example, `b'1,,2'.split(b',')` returns `[b'1', b'', b'2']`). The *sep* argument may consist of a multibyte

sequence (for example, `b'1<>2<>3'.split(b'<>')` returns `[b'1', b'2', b'3']`). Splitting an empty sequence with a specified separator returns `[b'']` or `[bytearray(b'')]` depending on the type of object being split. The *sep* argument may be any [bytes-like object](#).

For example:

```
>>> b'1,2,3'.split(b',')
[b'1', b'2', b'3']
>>> b'1,2,3'.split(b',', maxsplit=1)
[b'1', b'2,3']
>>> b'1,2,,3'.split(b',')
[b'1', b'2', b'', b'3', b'']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive ASCII whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the sequence has leading or trailing whitespace. Consequently, splitting an empty sequence or a sequence consisting solely of ASCII whitespace without a specified separator returns `[]`.

For example:

```
>>> b'1 2 3'.split()
[b'1', b'2', b'3']
>>> b'1 2 3'.split(maxsplit=1)
[b'1', b'2 3']
>>> b' 1 2 3 '.split()
[b'1', b'2', b'3']
```

`bytes.strip([chars])`

`bytearray.strip([chars])`

Return a copy of the sequence with specified leading and trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults

to removing ASCII whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> b'    spacious    '.strip()
b'spacious'
>>> b'www.example.com'.strip(b'cmowz.')
b'example'
```

The binary sequence of byte values to remove may be any [bytes-like object](#).

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

The following methods on bytes and bytearray objects assume the use of ASCII compatible binary formats and should not be applied to arbitrary binary data. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

bytes.capitalize()

bytearray.capitalize()

Return a copy of the sequence with each byte interpreted as an ASCII character, and the first byte capitalized and the rest lowercased. Non-ASCII byte values are passed through unchanged.

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.expandtabs(tabsize=8)`

`bytearray.expandtabs(tabsize=8)`

Return a copy of the sequence where all ASCII tab characters are replaced by one or more ASCII spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* bytes (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the sequence, the current column is set to zero and the sequence is examined byte by byte. If the byte is an ASCII tab character (`b'\t'`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the current byte is an ASCII newline (`b'\n'`) or carriage return (`b'\r'`), it is copied and the current column is reset to zero. Any other byte value is copied unchanged and the current column is incremented by one regardless of how the byte value is represented when printed:

```
>>> b'01\t012\t0123\t01234'.expandtabs()
b'01      012      0123      01234'
>>> b'01\t012\t0123\t01234'.expandtabs(4)
b'01  012 0123  01234'
```

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.isalnum()`

`bytearray.isalnum()`

Return `True` if all bytes in the sequence are alphabetical ASCII characters or ASCII decimal digits and the sequence is not empty, `False` otherwise. Alphanumeric ASCII characters are those byte values in the sequence

`b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`  
ASCII decimal digits are those byte values in the sequence

```
b'0123456789'.
```

For example:

```
>>> b'ABCa1'.isalnum()
True
>>> b'ABC a1'.isalnum()
False
```

`bytes.isalpha()`

`bytearray.isalpha()`

Return `True` if all bytes in the sequence are alphabetic ASCII characters and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence

```
b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ
```

For example:

```
>>> b'ABCa'.isalpha()
True
>>> b'ABCa1'.isalpha()
False
```

`bytes.isascii()`

`bytearray.isascii()`

Return `True` if the sequence is empty or all bytes in the sequence are ASCII, `False` otherwise. ASCII bytes are in the range 0-0x7F.

*New in version 3.7.*

`bytes.isdigit()`

`bytearray.isdigit()`

Return `True` if all bytes in the sequence are ASCII decimal digits and the sequence is not empty, `False` otherwise. ASCII decimal digits are those byte values in the sequence

```
b'0123456789'.
```

For example:

```
>>> b'1234'.isdigit()
True
>>> b'1.23'.isdigit()
False
```

`bytes.islower()`

`bytearray.islower()`

Return `True` if there is at least one lowercase ASCII character in the sequence and no uppercase ASCII characters, `False` otherwise.

For example:

```
>>> b'hello world'.islower()
True
>>> b'Hello world'.islower()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.isspace()`

`bytearray.isspace()`

Return `True` if all bytes in the sequence are ASCII whitespace and the sequence is not empty, `False` otherwise. ASCII whitespace characters are those byte values in the sequence `b' \t\n\r\x0b\f'` (space, tab, newline, carriage return, vertical tab, form feed).

`bytes.istitle()`

`bytearray.istitle()`

Return `True` if the sequence is ASCII titlecase and the sequence is not empty, `False` otherwise. See [bytes.title\(\)](#) for more details on the definition of

“titlecase”.

For example:

```
>>> b'Hello World'.istitle()
True
>>> b'Hello world'.istitle()
False
```

`bytes.isupper()`

`bytearray.isupper()`

Return `True` if there is at least one uppercase alphabetic ASCII character in the sequence and no lowercase ASCII characters, `False` otherwise.

For example:

```
>>> b'HELLO WORLD'.isupper()
True
>>> b'Hello world'.isupper()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.lower()`

`bytearray.lower()`

Return a copy of the sequence with all the uppercase ASCII characters converted to their corresponding lowercase counterpart.

For example:

```
>>> b'Hello World'.lower()
b'hello world'
```

Lowercase ASCII characters are those byte values in the

sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.splitlines(keepends = False)`  
`bytearray.splitlines(keepends = False)`

Return a list of the lines in the binary sequence, breaking at ASCII line boundaries. This method uses the [universal newlines](#) approach to splitting lines. Line breaks are not included in the resulting list unless *keepends* is given and true.

For example:

```
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines()
[b'ab c', b'', b'de fg', b'kl']
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
[b'ab c\n', b'\n', b'de fg\r', b'kl\r\n']
```

Unlike [split\(\)](#) when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> b"".split(b'\n'), b"Two lines\n".split(b'\n')
([], [b'Two lines', b''])
>>> b"".splitlines(), b"One line\n".splitlines()
([], [b'One line'])
```

`bytes.swapcase()`  
`bytearray.swapcase()`

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart and vice-versa.

For example:

```
>>> b'Hello World'.swapcase()  
b'hELLO wORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Unlike `str.swapcase()`, it is always the case that `bin.swapcase().swapcase() == bin` for the binary versions. Case conversions are symmetrical in ASCII, even though that is not generally true for arbitrary Unicode code points.

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.title()`

`bytearray.title()`

Return a titlecased version of the binary sequence where words start with an uppercase ASCII character and the remaining characters are lowercase. Uncased byte values are left unmodified.

For example:

```
>>> b'Hello world'.title()  
b'Hello World'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. All other byte values are uncased.

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> b"they're bill's friends from the UK".title()  
b"They'Re Bill'S Friends From The Uk"
```

A workaround for apostrophes can be constructed using regular expressions:

```
>>> import re  
>>> def titlecase(s):  
...     return re.sub(rb"[A-Za-z]+(' [A-Za-z]+)?",  
...                   lambda mo: mo.group(0)[0:1].upper()+  
...                               mo.group(0)[1:].lower(),  
...                   s)  
...  
>>> titlecase(b"they're bill's friends.")  
b"They're Bill's Friends."
```

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.upper()`

`bytearray.upper()`

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart.

For example:

```
>>> b'Hello World'.upper()  
b'HELLO WORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.zfill(width)`

`bytearray.zfill(width)`

Return a copy of the sequence left filled with ASCII `b'0'` digits to make a sequence of length *width*. A leading sign prefix (`b'+' / b'-'`) is handled by inserting the padding *after* the sign character rather than before. For [bytes](#) objects, the original sequence is returned if *width* is less than or equal to `len(seq)`.

For example:

```
>>> b"42".zfill(5)
b'00042'
>>> b"-42".zfill(5)
b'-0042'
```

### Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

## printf-style Bytes Formatting

### Note

The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). If the value being printed may be a tuple or dictionary, wrap it in a tuple.

Bytes objects (`bytes/bytearray`) have one unique built-in operation: the `%` operator (modulo). This is also known as the bytes *formatting* or *interpolation* operator. Given `format % values` (where *format* is a bytes object), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to using the `sprintf()` in the C language.

If *format* requires a single argument, *values* may be a single non-tuple object. [5](#) Otherwise, *values* must be a tuple with exactly the number of items specified by the format bytes object, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the bytes object *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted

from the mapping. For example:

```
>>> print(b'%(language)s has %(number)03d quote types.'  
...      {b'language': b"Python", b"number": 2})  
b'Python has 002 quote types.'
```

In this case no \* specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

### **Flagging**

---

The value conversion will use the “alternate form” (where defined below).

---

The conversion will be zero padded for numeric values.

---

The converted value is left adjusted (overrides the '0' conversion if both are given).

---

(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.

---

A sign character ('+' or '-') will precede the conversion (overrides a “space” flag).

---

A length modifier (h, l, or L) may be present, but is ignored as it is not necessary for Python – so e.g. %ld is identical to %d.

The conversion types are:

### **Conversion**

---

Signed integer decimal.

---

Signed integer decimal.

---

Signed octal value.

---

(d) Sole type – it is identical to 'd'.

---

Signed hexadecimal (lowercase).

---

Signed hexadecimal (uppercase).

---

(f) Floating point exponential format (lowercase).

---

(F) Floating point exponential format (uppercase).

---

(f) Floating point decimal format.

---

(F) Floating point decimal format.

---

(g) Floating point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.

---

**Formatting point format.** Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.

**Single byte** (accepts integer or single byte objects).

**Bytes** (any object that follows the [buffer protocol](#) or has `__bytes__()`).

**('b')** is an alias for 'b' and should only be used for Python2/3 code bases.

**Bytes** (converts any Python object using `repr(obj).encode('ascii', 'backslashreplace')`).

**('a')** is an alias for 'a' and should only be used for Python2/3 code bases.

**No argument is converted,** results in a '%' character in the result.

Notes:

1. The alternate form causes a leading octal specifier ('0o') to be inserted before the first digit.
2. The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.
3. The alternate form causes the result to always contain a decimal point, even if no digits follow it.

The precision determines the number of digits after the decimal point and defaults to 6.

4. The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

5. If precision is `N`, the output is truncated to `N` characters.
6. `b'%s'` is deprecated, but will not be removed during the 3.x series.

7. `b'%r'` is deprecated, but will not be removed during the 3.x series.
8. See [PEP 237](https://peps.python.org/pep-0237/) [https://peps.python.org/pep-0237/].

## Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

## See also

[PEP 461](https://peps.python.org/pep-0461/) [https://peps.python.org/pep-0461/] - Adding % formatting to bytes and bytearray

*New in version 3.5.*

## Memory Views

**memoryview** objects allow Python code to access the internal data of an object that supports the [buffer protocol](#) without copying.

*class* **memoryview**(*object*)

Create a **memoryview** that references *object*. *object* must support the buffer protocol. Built-in objects that support the buffer protocol include [bytes](#) and [bytearray](#).

A **memoryview** has the notion of an *element*, which is the atomic memory unit handled by the originating *object*. For many simple types such as [bytes](#) and [bytearray](#), an element is a single byte, but other types such as [array.array](#) may have bigger elements.

`len(view)` is equal to the length of [tolist](#). If `view.ndim = 0`, the length is 1. If `view.ndim = 1`, the length is equal to the number of elements in the view. For higher dimensions, the length is equal to the length of the nested list representation of the view. The [itemsize](#) attribute will give you the number of bytes in a single

element.

A **memoryview** supports slicing and indexing to expose its data. One-dimensional slicing will result in a subview:

```
>>> v = memoryview(b'abcefg')
>>> v[1]
98
>>> v[-1]
103
>>> v[1:4]
<memory at 0x7f3ddc9f4350>
>>> bytes(v[1:4])
b'bce'
```

If **format** is one of the native format specifiers from the **struct** module, indexing with an integer or a tuple of integers is also supported and returns a single *element* with the correct type. One-dimensional memoryviews can be indexed with an integer or a one-integer tuple. Multi-dimensional memoryviews can be indexed with tuples of exactly *ndim* integers where *ndim* is the number of dimensions. Zero-dimensional memoryviews can be indexed with the empty tuple.

Here is an example with a non-byte format:

```
>>> import array
>>> a = array.array('l', [-11111111, 22222222, -33333333])
>>> m = memoryview(a)
>>> m[0]
-11111111
>>> m[-1]
44444444
>>> m[:2].tolist()
[-11111111, -33333333]
```

If the underlying object is writable, the memoryview supports one-dimensional slice assignment. Resizing is not allowed:

```

>>> data = bytearray(b'abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = ord(b'z')
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = b'123'
>>> data
bytearray(b'z123fg')
>>> v[2:3] = b'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview assignment: lvalue and rvalue
>>> v[2:6] = b'spam'
>>> data
bytearray(b'z1spam')

```

One-dimensional memoryviews of [hashable](#) (read-only) types with formats 'B', 'b' or 'c' are also hashable. The hash is defined as `hash(m) == hash(m.tobytes())`:

```

>>> v = memoryview(b'abcefg')
>>> hash(v) == hash(b'abcefg')
True
>>> hash(v[2:4]) == hash(b'ce')
True
>>> hash(v[:-2]) == hash(b'abcefg'[:-2])
True

```

*Changed in version 3.3:* One-dimensional memoryviews can now be sliced. One-dimensional memoryviews with formats 'B', 'b' or 'c' are now [hashable](#).

*Changed in version 3.4:* memoryview is now registered automatically with [collections.abc.Sequence](#)

*Changed in version 3.5:* memoryviews can now be indexed with tuple of integers.

`memoryview` has several methods:

`_eq_(exporter)`

A `memoryview` and a [PEP 3118](https://peps.python.org/pep-3118/) [https://peps.python.org/pep-3118/] `exporter` are equal if their shapes are equivalent and if all corresponding values are equal when the operands' respective format codes are interpreted using `struct` syntax.

For the subset of `struct` format strings currently supported by `tolist()`, `v` and `w` are equal if `v.tolist() == w.tolist()`:

```
>>> import array
>>> a = array.array('I', [1, 2, 3, 4, 5])
>>> b = array.array('d', [1.0, 2.0, 3.0, 4.0, 5.0])
>>> c = array.array('b', [5, 3, 1])
>>> x = memoryview(a)
>>> y = memoryview(b)
>>> x == a == y == b
True
>>> x.tolist() == a.tolist() == y.tolist() == b.tolist()
True
>>> z = y[::-2]
>>> z == c
True
>>> z.tolist() == c.tolist()
True
```

If either format string is not supported by the `struct` module, then the objects will always compare as unequal (even if the format strings and buffer contents are identical):

```
>>> from ctypes import BigEndianStructure, c_long
>>> class BEPoint(BigEndianStructure):
...     _fields_ = [("x", c_long), ("y", c_long)]
...
>>> point = BEPoint(100, 200)
```

```
>>> a = memoryview(point)
>>> b = memoryview(point)
>>> a == point
False
>>> a == b
False
```

Note that, as with floating point numbers, `v is w` does *not* imply `v == w` for memoryview objects.

*Changed in version 3.3:* Previous versions compared the raw memory disregarding the item format and the logical array structure.

`tobytes(order='C')`

Return the data in the buffer as a bytestring. This is equivalent to calling the `bytes` constructor on the memoryview.

```
>>> m = memoryview(b"abc")
>>> m.tobytes()
b'abc'
>>> bytes(m)
b'abc'
```

For non-contiguous arrays the result is equal to the flattened list representation with all elements converted to bytes. `tobytes()` supports all format strings, including those that are not in `struct` module syntax.

*New in version 3.8:* `order` can be `{'C', 'F', 'A'}`. When `order` is `'C'` or `'F'`, the data of the original array is converted to C or Fortran order. For contiguous views, `'A'` returns an exact copy of the physical memory. In particular, in-memory Fortran order is preserved. For non-contiguous views, the data is converted to C first. `order=None` is the same as `order='C'`.

`hex([sep[, bytes_per_sep]])`

Return a string object containing two hexadecimal digits for each byte in the buffer.

```
>>> m = memoryview(b"abc")
>>> m.hex()
'616263'
```

*New in version 3.5.*

*Changed in version 3.8:* Similar to `bytes.hex()`, `memoryview.hex()` now supports optional `sep` and `bytes_per_sep` parameters to insert separators between bytes in the hex output.

## `tolist()`

Return the data in the buffer as a list of elements.

```
>>> memoryview(b'abc').tolist()
[97, 98, 99]
>>> import array
>>> a = array.array('d', [1.1, 2.2, 3.3])
>>> m = memoryview(a)
>>> m.tolist()
[1.1, 2.2, 3.3]
```

*Changed in version 3.3:* `tolist()` now supports all single character native formats in `struct` module syntax as well as multi-dimensional representations.

## `toreadonly()`

Return a readonly version of the memoryview object. The original memoryview object is unchanged.

```
>>> m = memoryview(bytearray(b'abc'))
>>> mm = m.toreadonly()
>>> mm.tolist()
[89, 98, 99]
>>> mm[0] = 42
Traceback (most recent call last):
```

```

File "<stdin>", line 1, in <module>
TypeError: cannot modify read-only memory
>>> m[0] = 43
>>> mm.tolist()
[43, 98, 99]

```

*New in version 3.8.*

## release()

Release the underlying buffer exposed by the memoryview object. Many objects take special actions when a view is held on them (for example, a [bytearray](#) would temporarily forbid resizing); therefore, calling `release()` is handy to remove these restrictions (and free any dangling resources) as soon as possible.

After this method has been called, any further operation on the view raises a [ValueError](#) (except [release\(\)](#) itself which can be called multiple times):

```

>>> m = memoryview(b'abc')
>>> m.release()
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memory

```

The context management protocol can be used for a similar effect, using the `with` statement:

```

>>> with memoryview(b'abc') as m:
...     m[0]
...
97
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memory

```

*New in version 3.2.*

`cast(format[, shape])`

Cast a memoryview to a new format or shape. *shape* defaults to `[byte_length//new_itemsize]`, which means that the result view will be one-dimensional. The return value is a new memoryview, but the buffer itself is not copied. Supported casts are 1D -> C-contiguous and C-contiguous -> 1D.

The destination format is restricted to a single element native format in `struct` syntax. One of the formats must be a byte format ('B', 'b' or 'c'). The byte length of the result must be the same as the original length.

Cast 1D/long to 1D/unsigned bytes:

```
>>> import array
>>> a = array.array('l', [1,2,3])
>>> x = memoryview(a)
>>> x.format
'l'
>>> x.itemsize
8
>>> len(x)
3
>>> x.nbytes
24
>>> y = x.cast('B')
>>> y.format
'B'
>>> y.itemsize
1
>>> len(y)
24
>>> y.nbytes
24
```

Cast 1D/unsigned bytes to 1D/char:

```

>>> b = bytearray(b'zyz')
>>> x = memoryview(b)
>>> x[0] = b'a'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview: invalid value for format
>>> y = x.cast('c')
>>> y[0] = b'a'
>>> b
bytearray(b'ayz')

```

Cast 1D/bytes to 3D/ints to 1D/signed char:

```

>>> import struct
>>> buf = struct.pack("i"*12, *list(range(12)))
>>> x = memoryview(buf)
>>> y = x.cast('i', shape=[2,2,3])
>>> y.tolist()
[[[0, 1, 2], [3, 4, 5]], [[6, 7, 8], [9, 10, 11]]]
>>> y.format
'i'
>>> y.itemsize
4
>>> len(y)
2
>>> y.nbytes
48
>>> z = y.cast('b')
>>> z.format
'b'
>>> z.itemsize
1
>>> len(z)
48
>>> z.nbytes
48

```

Cast 1D/unsigned long to 2D/unsigned long:

```

>>> buf = struct.pack("L"*6, *list(range(6)))
>>> x = memoryview(buf)
>>> y = x.cast('L', shape=[2,3])
>>> len(y)
2
>>> y.nbytes
48
>>> y.tolist()
[[0, 1, 2], [3, 4, 5]]

```

*New in version 3.3.*

*Changed in version 3.5:* The source format is no longer restricted when casting to a byte view.

There are also several readonly attributes available:

**obj**

The underlying object of the memoryview:

```

>>> b = bytearray(b'xyz')
>>> m = memoryview(b)
>>> m.obj is b
True

```

*New in version 3.3.*

**nbytes**

`nbytes == product(shape) * itemsize == len(m.tobytes())`. This is the amount of space in bytes that the array would use in a contiguous representation. It is not necessarily equal to `len(m)`:

```

>>> import array
>>> a = array.array('i', [1,2,3,4,5])
>>> m = memoryview(a)
>>> len(m)
5
>>> m.nbytes

```

```

20
>>> y = m[:,2]
>>> len(y)
3
>>> y.nbytes
12
>>> len(y.tobytes())
12

```

### Multi-dimensional arrays:

```

>>> import struct
>>> buf = struct.pack("d"*12, *[1.5*x for x in
>>> x = memoryview(buf)
>>> y = x.cast('d', shape=[3,4])
>>> y.tolist()
[[0.0, 1.5, 3.0, 4.5], [6.0, 7.5, 9.0, 10.5],
>>> len(y)
3
>>> y.nbytes
96

```

### *New in version 3.3.*

#### readonly

A bool indicating whether the memory is read only.

#### format

A string containing the format (in `struct` module style) for each element in the view. A memoryview can be created from exporters with arbitrary format strings, but some methods (e.g. `tolist()`) are restricted to native single element formats.

*Changed in version 3.3:* format `'B'` is now handled according to the struct module syntax. This means that `memoryview(b'abc')[0] == b'abc'[0] == 97`.

#### itemsizes

The size in bytes of each element of the memoryview:

```
>>> import array, struct
>>> m = memoryview(array.array('H', [32000, 32000]))
>>> m.itemsize
2
>>> m[0]
32000
>>> struct.calcsize('H') == m.itemsize
True
```

**ndim**

An integer indicating how many dimensions of a multi-dimensional array the memory represents.

**shape**

A tuple of integers the length of **ndim** giving the shape of the memory as an N-dimensional array.

*Changed in version 3.3:* An empty tuple instead of `None` when `ndim = 0`.

**strides**

A tuple of integers the length of **ndim** giving the size in bytes to access each element for each dimension of the array.

*Changed in version 3.3:* An empty tuple instead of `None` when `ndim = 0`.

**suboffsets**

Used internally for PIL-style arrays. The value is informational only.

**c\_contiguous**

A bool indicating whether the memory is C-contiguous.

*New in version 3.3.*

`f_contiguous`

A bool indicating whether the memory is Fortran [contiguous](#).

*New in version 3.3.*

`contiguous`

A bool indicating whether the memory is [contiguous](#).

*New in version 3.3.*

## Set Types — [set](#), [frozenset](#)

A *set* object is an unordered collection of distinct [hashable](#) objects. Common uses include membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference. (For other containers see the built-in [dict](#), [list](#), and [tuple](#) classes, and the [collections](#) module.)

Like other collections, sets support `x in set`, `len(set)`, and `for x in set`. Being an unordered collection, sets do not record element position or order of insertion. Accordingly, sets do not support indexing, slicing, or other sequence-like behavior.

There are currently two built-in set types, [set](#) and [frozenset](#). The [set](#) type is mutable — the contents can be changed using methods like `add()` and `remove()`. Since it is mutable, it has no hash value and cannot be used as either a dictionary key or as an element of another set. The [frozenset](#) type is immutable and [hashable](#) — its contents cannot be altered after it is created; it can therefore be used as a dictionary key or as an element of another set.

Non-empty sets (not frozensets) can be created by placing a comma-separated list of elements within braces, for example: `{'jack', 'sjoerd'}`, in addition to the [set](#) constructor.

The constructors for both classes work the same:

`class set([iterable])`

`class frozenset([iterable])`

Return a new set or frozenset object whose elements are taken from *iterable*. The elements of a set must be [hashable](#). To represent sets of sets, the inner sets must be [frozenset](#) objects. If *iterable* is not specified, a new empty set is returned.

Sets can be created by several means:

- Use a comma-separated list of elements within braces:  
`{'jack', 'sjoerd'}`
- Use a set comprehension: `{c for c in 'abracadabra' if c not in 'abc'}`
- Use the type constructor: `set()`, `set('foobar')`, `set(['a', 'b', 'foo'])`

Instances of [set](#) and [frozenset](#) provide the following operations:

`len(s)`

Return the number of elements in set *s* (cardinality of *s*).

`x in s`

Test *x* for membership in *s*.

`x not in s`

Test *x* for non-membership in *s*.

`isdisjoint(other)`

Return `True` if the set has no elements in common with *other*. Sets are disjoint if and only if their intersection is the empty set.

`issubset(other)`

`set <= other`

Test whether every element in the set is in *other*.

`set < other`

Test whether the set is a proper subset of *other*, that is,  
`set <= other` and `set != other`.

`issuperset(other)`

`set >= other`

Test whether every element in *other* is in the set.

`set > other`

Test whether the set is a proper superset of *other*, that is,  
`set >= other` and `set != other`.

`union(*others)`

`set | other | ...`

Return a new set with elements from the set and all others.

`intersection(*others)`

`set & other & ...`

Return a new set with elements common to the set and all others.

`difference(*others)`

`set - other - ...`

Return a new set with elements in the set that are not in the others.

`symmetric_difference(other)`

`set ^ other`

Return a new set with elements in either the set or *other* but not both.

`copy()`

Return a shallow copy of the set.

Note, the non-operator versions of `union()`,

`intersection()`, `difference()`, `symmetric_difference()`, `issubset()`, and `issuperset()` methods will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `set('abc') & 'cbs'` in favor of the more readable `set('abc').intersection('cbs')`.

Both `set` and `frozenset` support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

Instances of `set` are compared to instances of `frozenset` based on their members. For example, `set('abc') == frozenset('abc')` returns `True` and so does `set('abc') in set([frozenset('abc')])`.

The subset and equality comparisons do not generalize to a total ordering function. For example, any two nonempty disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False`: `a < b`, `a == b`, or `a > b`.

Since sets only define partial ordering (subset relationships), the output of the `list.sort()` method is undefined for lists of sets.

Set elements, like dictionary keys, must be `hashable`.

Binary operations that mix `set` instances with `frozenset` return the type of the first operand. For example: `frozenset('ab') | set('bc')` returns an instance of `frozenset`.

The following table lists operations available for `set` that do not apply to immutable instances of `frozenset`:

`update(*others)`

`set |= other | ...`

Update the set, adding elements from all others.

`intersection_update(*others)`

`set &= other & ...`

Update the set, keeping only elements found in it and all others.

`difference_update(*others)`

`set -= other | ...`

Update the set, removing elements found in others.

`symmetric_difference_update(other)`

`set ^= other`

Update the set, keeping only elements found in either set, but not in both.

`add(elem)`

Add element *elem* to the set.

`remove(elem)`

Remove element *elem* from the set. Raises **KeyError** if *elem* is not contained in the set.

`discard(elem)`

Remove element *elem* from the set if it is present.

`pop()`

Remove and return an arbitrary element from the set. Raises **KeyError** if the set is empty.

`clear()`

Remove all elements from the set.

Note, the non-operator versions of the `update()`,

`intersection_update()`, `difference_update()`, and `symmetric_difference_update()` methods will accept any iterable as an argument.

Note, the *elem* argument to the `__contains__()`, `remove()`, and `discard()` methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

## Mapping Types — `dict`

A `mapping` object maps `hashable` values to arbitrary objects. Mappings are mutable objects. There is currently only one standard mapping type, the *dictionary*. (For other containers see the built-in `list`, `set`, and `tuple` classes, and the `collections` module.)

A dictionary's keys are *almost* arbitrary values. Values that are not `hashable`, that is, values containing lists, dictionaries or other mutable types (that are compared by value rather than by object identity) may not be used as keys. Values that compare equal (such as `1`, `1.0`, and `True`) can be used interchangeably to index the same dictionary entry.

```
class dict(**kwargs)
class dict(mapping, **kwargs)
class dict(iterable, **kwargs)
```

Return a new dictionary initialized from an optional positional argument and a possibly empty set of keyword arguments.

Dictionaries can be created by several means:

- Use a comma-separated list of `key: value` pairs within braces: `{'jack': 4098, 'sjoerd': 4127}` or `{4098: 'jack', 4127: 'sjoerd'}`
- Use a dict comprehension: `{}, {x: x ** 2 for x in range(10)}`
- Use the type constructor: `dict()`, `dict([('foo', 100), ('bar', 200)])`, `dict(foo=100,`

```
bar=200)
```

If no positional argument is given, an empty dictionary is created. If a positional argument is given and it is a mapping object, a dictionary is created with the same key-value pairs as the mapping object. Otherwise, the positional argument must be an [iterable](#) object. Each item in the iterable must itself be an iterable with exactly two objects. The first object of each item becomes a key in the new dictionary, and the second object the corresponding value. If a key occurs more than once, the last value for that key becomes the corresponding value in the new dictionary.

If keyword arguments are given, the keyword arguments and their values are added to the dictionary created from the positional argument. If a key being added is already present, the value from the keyword argument replaces the value from the positional argument.

To illustrate, the following examples all return a dictionary equal to {"one": 1, "two": 2, "three": 3}:

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> f = dict({'one': 1, 'three': 3}, two=2)
>>> a == b == c == d == e == f
True
```

Providing keyword arguments as in the first example only works for keys that are valid Python identifiers. Otherwise, any valid keys can be used.

These are the operations that dictionaries support (and therefore, custom mapping types should support too):

`list(d)`

Return a list of all the keys used in the dictionary *d*.

`len(d)`

Return the number of items in the dictionary *d*.

`d[key]`

Return the item of *d* with key *key*. Raises a **KeyError** if *key* is not in the map.

If a subclass of dict defines a method `__missing__()` and *key* is not present, the `d[key]` operation calls that method with the key *key* as argument. The `d[key]` operation then returns or raises whatever is returned or raised by the `__missing__(key)` call. No other operations or methods invoke `__missing__()`. If `__missing__()` is not defined, **KeyError** is raised. `__missing__()` must be a method; it cannot be an instance variable:

```
>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

The example above shows part of the implementation of **collections.Counter**. A different `__missing__` method is used by **collections.defaultdict**.

`d[key] = value`

Set `d[key]` to *value*.

`del d[key]`

Remove `d[key]` from *d*. Raises a **KeyError** if *key* is not in the map.

key in d

Return `True` if *d* has a key *key*, else `False`.

key not in d

Equivalent to `not key in d`.

iter(d)

Return an iterator over the keys of the dictionary. This is a shortcut for `iter(d.keys())`.

clear()

Remove all items from the dictionary.

copy()

Return a shallow copy of the dictionary.

*classmethod* fromkeys(*iterable*[, *value*])

Create a new dictionary with keys from *iterable* and values set to *value*.

**fromkeys()** is a class method that returns a new dictionary. *value* defaults to `None`. All of the values refer to just a single instance, so it generally doesn't make sense for *value* to be a mutable object such as an empty list. To get distinct values, use a [dict comprehension](#) instead.

get(*key*[, *default*])

Return the value for *key* if *key* is in the dictionary, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a **KeyError**.

items()

Return a new view of the dictionary's items ((*key*, *value*) pairs). See the [documentation of view objects](#).

`keys()`

Return a new view of the dictionary's keys. See the [documentation of view objects](#).

`pop(key[, default])`

If *key* is in the dictionary, remove it and return its value, else return *default*. If *default* is not given and *key* is not in the dictionary, a **KeyError** is raised.

`popitem()`

Remove and return a (key, value) pair from the dictionary. Pairs are returned in LIFO order.

**popitem()** is useful to destructively iterate over a dictionary, as often used in set algorithms. If the dictionary is empty, calling **popitem()** raises a **KeyError**.

*Changed in version 3.7:* LIFO order is now guaranteed. In prior versions, **popitem()** would return an arbitrary key/value pair.

`reversed(d)`

Return a reverse iterator over the keys of the dictionary. This is a shortcut for `reversed(d.keys())`.

*New in version 3.8.*

`setdefault(key[, default])`

If *key* is in the dictionary, return its value. If not, insert *key* with a value of *default* and return *default*. *default* defaults to `None`.

`update([other])`

Update the dictionary with the key/value pairs from *other*, overwriting existing keys. Return `None`.

`update()` accepts either another dictionary object or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs: `d.update(red=1, blue=2)`.

## `values()`

Return a new view of the dictionary's values. See the [documentation of view objects](#).

An equality comparison between one `dict.values()` view and another will always return `False`. This also applies when comparing `dict.values()` to itself:

```
>>> d = {'a': 1}
>>> d.values() == d.values()
False
```

## `d | other`

Create a new dictionary with the merged keys and values of *d* and *other*, which must both be dictionaries. The values of *other* take priority when *d* and *other* share keys.

*New in version 3.9.*

## `d |= other`

Update the dictionary *d* with keys and values from *other*, which may be either a [mapping](#) or an [iterable](#) of key/value pairs. The values of *other* take priority when *d* and *other* share keys.

*New in version 3.9.*

Dictionaries compare equal if and only if they have the same (key, value) pairs (regardless of ordering). Order comparisons (`'<'`, `'<='`, `'>='`, `'>'`) raise [TypeError](#).

Dictionaries preserve insertion order. Note that updating a

key does not affect the order. Keys added after deletion are inserted at the end.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(d)
['one', 'two', 'three', 'four']
>>> list(d.values())
[1, 2, 3, 4]
>>> d["one"] = 42
>>> d
{'one': 42, 'two': 2, 'three': 3, 'four': 4}
>>> del d["two"]
>>> d["two"] = None
>>> d
{'one': 42, 'three': 3, 'four': 4, 'two': None}
```

*Changed in version 3.7:* Dictionary order is guaranteed to be insertion order. This behavior was an implementation detail of CPython from 3.6.

Dictionaries and dictionary views are reversible.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(reversed(d))
['four', 'three', 'two', 'one']
>>> list(reversed(d.values()))
[4, 3, 2, 1]
>>> list(reversed(d.items()))
[('four', 4), ('three', 3), ('two', 2), ('one', 1)]
```

*Changed in version 3.8:* Dictionaries are now reversible.

**See also**

[`types.MappingProxyType`](#) can be used to create a read-only

view of a `dict`.

## Dictionary view objects

The objects returned by `dict.keys()`, `dict.values()` and `dict.items()` are *view objects*. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes.

Dictionary views can be iterated over to yield their respective data, and support membership tests:

`len(dictview)`

Return the number of entries in the dictionary.

`iter(dictview)`

Return an iterator over the keys, values or items (represented as tuples of `(key, value)`) in the dictionary.

Keys and values are iterated over in insertion order. This allows the creation of `(value, key)` pairs using `zip()`: `pairs = zip(d.values(), d.keys())`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.items()]`.

Iterating views while adding or deleting entries in the dictionary may raise a `RuntimeError` or fail to iterate over all entries.

*Changed in version 3.7:* Dictionary order is guaranteed to be insertion order.

`x in dictview`

Return `True` if `x` is in the underlying dictionary's keys, values or items (in the latter case, `x` should be a `(key, value)` tuple).

`reversed(dictview)`

Return a reverse iterator over the keys, values or items of the

dictionary. The view will be iterated in reverse order of the insertion.

*Changed in version 3.8:* Dictionary views are now reversible.

`dictview.mapping`

Return a `types.MappingProxyType` that wraps the original dictionary to which the view refers.

*New in version 3.10.*

Keys views are set-like since their entries are unique and [hashable](#). If all values are hashable, so that `(key, value)` pairs are unique and hashable, then the items view is also set-like. (Values views are not treated as set-like since the entries are generally not unique.) For set-like views, all of the operations defined for the abstract base class `collections.abc.Set` are available (for example, `==`, `<`, or `^`).

An example of dictionary view usage:

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.keys()
>>> values = dishes.values()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
>>> print(n)
504

>>> # keys and values are iterated over in the same order
>>> list(keys)
['eggs', 'sausage', 'bacon', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
```

```

>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['bacon', 'spam']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
>>> keys ^ {'sausage', 'juice'}
{'juice', 'sausage', 'bacon', 'spam'}

>>> # get back a read-only proxy for the original dictionary
>>> values.mapping
mappingproxy({'bacon': 1, 'spam': 500})
>>> values.mapping['spam']
500

```

## Context Manager Types

Python's **with** statement supports the concept of a runtime context defined by a context manager. This is implemented using a pair of methods that allow user-defined classes to define a runtime context that is entered before the statement body is executed and exited when the statement ends:

`contextmanager._enter_()`

Enter the runtime context and return either this object or another object related to the runtime context. The value returned by this method is bound to the identifier in the **as** clause of **with** statements using this context manager.

An example of a context manager that returns itself is a [file object](#). File objects return themselves from `_enter_()` to allow [open\(\)](#) to be used as the context expression in a **with** statement.

An example of a context manager that returns a related object is the one returned by `decimal.localcontext()`. These managers set the active decimal context to a copy of the

original decimal context and then return the copy. This allows changes to be made to the current decimal context in the body of the `with` statement without affecting code outside the `with` statement.

`contextmanager._exit_(exc_type, exc_val, exc_tb)`

Exit the runtime context and return a Boolean flag indicating if any exception that occurred should be suppressed. If an exception occurred while executing the body of the `with` statement, the arguments contain the exception type, value and traceback information. Otherwise, all three arguments are `None`.

Returning a true value from this method will cause the `with` statement to suppress the exception and continue execution with the statement immediately following the `with` statement. Otherwise the exception continues propagating after this method has finished executing. Exceptions that occur during execution of this method will replace any exception that occurred in the body of the `with` statement.

The exception passed in should never be reraised explicitly - instead, this method should return a false value to indicate that the method completed successfully and does not want to suppress the raised exception. This allows context management code to easily detect whether or not an `__exit__()` method has actually failed.

Python defines several context managers to support easy thread synchronisation, prompt closure of files or other objects, and simpler manipulation of the active decimal arithmetic context. The specific types are not treated specially beyond their implementation of the context management protocol. See the `contextlib` module for some examples.

Python's `generators` and the `contextlib.contextmanager` decorator provide a convenient way to implement these protocols. If a generator function is decorated with the `contextlib.contextmanager` decorator, it will return a context manager implementing the necessary `__enter__()` and

`__exit__()` methods, rather than the iterator produced by an undecorated generator function.

Note that there is no specific slot for any of these methods in the type structure for Python objects in the Python/C API. Extension types wanting to define these methods must provide them as a normal Python accessible method. Compared to the overhead of setting up the runtime context, the overhead of a single class dictionary lookup is negligible.

## Type Annotation Types — Generic Alias, Union

The core built-in types for [type annotations](#) are [Generic Alias](#) and [Union](#).

### Generic Alias Type

`GenericAlias` objects are generally created by [subscripting](#) a class. They are most often used with [container classes](#), such as [list](#) or [dict](#). For example, `list[int]` is a `GenericAlias` object created by subscripting the `list` class with the argument [int](#). `GenericAlias` objects are intended primarily for use with [type annotations](#).

#### Note

It is generally only possible to subscript a class if the class implements the special method `__class_getitem__()`.

A `GenericAlias` object acts as a proxy for a [generic type](#), implementing *parameterized generics*.

For a container class, the argument(s) supplied to a [subscription](#) of the class may indicate the type(s) of the elements an object contains. For example, `set[bytes]` can be used in type annotations to signify a [set](#) in which all the elements are of type [bytes](#).

For a class which defines `__class_getitem__()` but is not a container, the argument(s) supplied to a subscription of the class will often indicate the return type(s) of one or more methods defined on an object. For example, `regular expressions` can be used on both the `str` data type and the `bytes` data type:

- If `x = re.search('foo', 'foo')`, `x` will be a `re.Match` object where the return values of `x.group(0)` and `x[0]` will both be of type `str`. We can represent this kind of object in type annotations with the `GenericAlias` `re.Match[str]`.
- If `y = re.search(b'bar', b'bar')`, (note the `b` for `bytes`), `y` will also be an instance of `re.Match`, but the return values of `y.group(0)` and `y[0]` will both be of type `bytes`. In type annotations, we would represent this variety of `re.Match` objects with `re.Match[bytes]`.

`GenericAlias` objects are instances of the class `types.GenericAlias`, which can also be used to create `GenericAlias` objects directly.

`T[X, Y, ...]`

Creates a `GenericAlias` representing a type `T` parameterized by types `X`, `Y`, and more depending on the `T` used. For example, a function expecting a `list` containing `float` elements:

```
def average(values: list[float]) -> float:
    return sum(values) / len(values)
```

Another example for `mapping` objects, using a `dict`, which is a generic type expecting two type parameters representing the key type and the value type. In this example, the function expects a `dict` with keys of type `str` and values of type `int`:

```
def send_post_request(url: str, body: dict[str, int]
    ...
```

The builtin functions `isinstance()` and `issubclass()` do not

accept `GenericAlias` types for their second argument:

```
>>> isinstance([1, 2], list[str])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: isinstance() argument 2 cannot be a parameter
```

The Python runtime does not enforce [type annotations](#). This extends to generic types and their type parameters. When creating a container object from a `GenericAlias`, the elements in the container are not checked against their type. For example, the following code is discouraged, but will run without errors:

```
>>> t = list[str]
>>> t([1, 2, 3])
[1, 2, 3]
```

Furthermore, parameterized generics erase type parameters during object creation:

```
>>> t = list[str]
>>> type(t)
<class 'types.GenericAlias'>

>>> l = t()
>>> type(l)
<class 'list'>
```

Calling [repr\(\)](#) or [str\(\)](#) on a generic shows the parameterized type:

```
>>> repr(list[int])
'list[int]'
```

```
>>> str(list[int])
'list[int]'
```

The [\\_\\_getitem\\_\\_\(\)](#) method of generic containers will raise an exception to disallow mistakes like `dict[str][str]`:

```
>>> dict[str][str]
```

```
Traceback (most recent call last):
```

```
File "<stdin>", line 1, in <module>
```

```
TypeError: There are no type variables left in dict[str]
```

However, such expressions are valid when [type variables](#) are used. The index must have as many elements as there are type variable items in the `GenericAlias` object's `__args__`.

```
>>> from typing import TypeVar
>>> Y = TypeVar('Y')
>>> dict[str, Y][int]
dict[str, int]
```

## Standard Generic Classes

The following standard library classes support parameterized generics. This list is non-exhaustive.

- [tuple](#)
- [list](#)
- [dict](#)
- [set](#)
- [frozenset](#)
- [type](#)
- [collections.deque](#)
- [collections.defaultdict](#)
- [collections.OrderedDict](#)
- [collections.Counter](#)
- [collections.ChainMap](#)
- [collections.abc.Awaitable](#)
- [collections.abc.Coroutine](#)
- [collections.abc.AsyncIterable](#)
- [collections.abc.AsyncIterator](#)
- [collections.abc.AsyncGenerator](#)
- [collections.abc.Iterable](#)
- [collections.abc.Iterator](#)
- [collections.abc.Generator](#)
- [collections.abc.Reversible](#)
- [collections.abc.Container](#)
- [collections.abc.Collection](#)

- `collections.abc.Callable`
- `collections.abc.Set`
- `collections.abc.MutableSet`
- `collections.abc.Mapping`
- `collections.abc.MutableMapping`
- `collections.abc.Sequence`
- `collections.abc.MutableSequence`
- `collections.abc.ByteString`
- `collections.abc.MappingView`
- `collections.abc.KeysView`
- `collections.abc.ItemsView`
- `collections.abc.ValuesView`
- `contextlib.AbstractContextManager`
- `contextlib.AbstractAsyncContextManager`

## Special Attributes of `GenericAlias` objects

All parameterized generics implement special read-only attributes.

`genericalias._origin_`

This attribute points at the non-parameterized generic class:

```
>>> list[int].__origin__  
<class 'list'>
```

### `genericalias.__args__`

This attribute is a **tuple** (possibly of length 1) of generic types passed to the original `__class_getitem__()` of the generic class:

```
>>> dict[str, list[int]].__args__  
(<class 'str'>, list[int])
```

### `genericalias.__parameters__`

This attribute is a lazily computed tuple (possibly empty) of unique type variables found in `__args__`:

```
>>> from typing import TypeVar  
  
>>> T = TypeVar('T')  
>>> list[T].__parameters__  
(~T,)
```

### Note

A `GenericAlias` object with `typing.ParamSpec` parameters may not have correct `__parameters__` after substitution because `typing.ParamSpec` is intended primarily for static type checking.

### `genericalias.__unpacked__`

A boolean that is true if the alias has been unpacked using the `*` operator (see **`TypeVarTuple`**).

*New in version 3.11.*

Introducing the ability to natively parameterize standard-library classes, provided they implement the special class method `__class_getitem__()`.

## Generics, user-defined generics and `typing.Generic`

Documentation on how to implement generic classes that can be parameterized at runtime and understood by static type-checkers.

*New in version 3.9.*

## Union Type

A union object holds the value of the `|` (bitwise or) operation on multiple [type objects](#). These types are intended primarily for [type annotations](#). The union type expression enables cleaner type hinting syntax compared to [typing.Union](#).

`X | Y | ...`

Defines a union object which holds types `X`, `Y`, and so forth.

`X | Y` means either `X` or `Y`. It is equivalent to `typing.Union[X, Y]`. For example, the following function expects an argument of type [int](#) or [float](#):

```
def square(number: int | float) -> int | float:
    return number ** 2
```

### Note

The `|` operand cannot be used at runtime to define unions where one or more members is a forward reference. For example, `int | "Foo"`, where `"Foo"` is a reference to a class not yet defined, will fail at runtime. For unions which include forward references, present the whole expression as a string, e.g. `"int | Foo"`.

`union_object == other`

Union objects can be tested for equality with other union objects. Details:

- Unions of unions are flattened:

```
(int | str) | float == int | str | float
```

- Redundant types are removed:

```
int | str | int == int | str
```

- When comparing unions, the order is ignored:

```
int | str == str | int
```

- It is compatible with `typing.Union`:

```
int | str == typing.Union[int, str]
```

- Optional types can be spelled as a union with `None`:

```
str | None == typing.Optional[str]
```

`isinstance(obj, union_object)`

`issubclass(obj, union_object)`

Calls to `isinstance()` and `issubclass()` are also supported with a union object:

```
>>> isinstance("", int | str)
True
```

However, union objects containing [parameterized generics](#) cannot be used:

```
>>> isinstance(1, int | list[int])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: isinstance() argument 2 cannot contain a
```

The user-exposed type for the union object can be accessed from `types.UnionType` and used for `isinstance()` checks. An object cannot be instantiated from the type:

```
>>> import types
>>> isinstance(int | str, types.UnionType)
True
>>> types.UnionType()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot create 'types.UnionType' instances
```

## Note

The `__or__()` method for type objects was added to support the syntax `X | Y`. If a metaclass implements `__or__()`, the Union may override it:

```
>>> class M(type):
...     def __or__(self, other):
...         return "Hello"
...
>>> class C(metaclass=M):
...     pass
...
>>> C | int
'Hello'
>>> int | C
int | __main__.C
```

## See also

**PEP 604** [<https://peps.python.org/pep-0604/>] – PEP proposing the `X | Y` syntax and the Union type.

*New in version 3.10.*

## Other Built-in Types

The interpreter supports several other kinds of objects. Most of these support only one or two operations.

## Modules

The only special operation on a module is attribute access: `m.name`, where *m* is a module and *name* accesses a name defined in *m*'s symbol table. Module attributes can be assigned to. (Note that the `import` statement is not, strictly speaking, an operation on a module object; `import foo` does not require a module object named *foo* to exist, rather it requires an (external) *definition* for a module named *foo* somewhere.)

A special attribute of every module is `__dict__`. This is the dictionary containing the module's symbol table. Modifying this dictionary will actually change the module's symbol table, but direct assignment to the `__dict__` attribute is not possible (you can write `m.__dict__['a'] = 1`, which defines `m.a` to be 1, but you can't write `m.__dict__ = {}`). Modifying `__dict__` directly is not recommended.

Modules built into the interpreter are written like this: `<module 'sys' (built-in)>`. If loaded from a file, they are written as `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

## Classes and Class Instances

See [Objects, values and types](#) and [Class definitions](#) for these.

## Functions

Function objects are created by function definitions. The only operation on a function object is to call it: `func(argument-list)`.

There are really two flavors of function objects: built-in functions and user-defined functions. Both support the same operation (to call the function), but the implementation is different, hence the different object types.

See [Function definitions](#) for more information.

## Methods

Methods are functions that are called using the attribute notation. There are two flavors: built-in methods (such as `append()` on lists) and class instance methods. Built-in methods are described with the types that support them.

If you access a method (a function defined in a class namespace) through an instance, you get a special object: a *bound method* (also called *instance method*) object. When called, it will add the `self` argument to the argument list. Bound methods have two special read-only attributes: `m.__self__` is the object on which the method operates, and `m.__func__` is the function implementing the method. Calling `m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.__func__(m.__self__, arg-1, arg-2, ..., arg-n)`.

Like function objects, bound method objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`meth.__func__`), setting method attributes on bound methods is disallowed. Attempting to set an attribute on a method results in an [AttributeError](#) being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object:

```
>>> class C:
...     def method(self):
...         pass
...
>>> c = C()
>>> c.method.whoami = 'my name is method' # can't set c
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'method' object has no attribute 'whoami'
>>> c.method.__func__.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

See [The standard type hierarchy](#) for more information.

## Code Objects

Code objects are used by the implementation to represent “pseudo-compiled” executable Python code such as a function body. They differ from function objects because they don’t contain a reference to their global execution environment. Code objects are returned by the built-in `compile()` function and can be extracted from function objects through their `__code__` attribute. See also the `code` module.

Accessing `__code__` raises an [auditing event](#) `object.__getattr__` with arguments `obj` and `"__code__"`.

A code object can be executed or evaluated by passing it (instead of a source string) to the `exec()` or `eval()` built-in functions.

See [The standard type hierarchy](#) for more information.

## Type Objects

Type objects represent the various object types. An object’s type is accessed by the built-in function `type()`. There are no special operations on types. The standard module `types` defines names for all standard built-in types.

Types are written like this: `<class 'int'>`.

## The Null Object

This object is returned by functions that don’t explicitly return a value. It supports no special operations. There is exactly one null object, named `None` (a built-in name). `type(None)()` produces the same singleton.

It is written as `None`.

## The Ellipsis Object

This object is commonly used by slicing (see [Slicings](#)). It supports no special operations. There is exactly one ellipsis object, named **Ellipsis** (a built-in name). `type(Ellipsis)()` produces the **Ellipsis** singleton.

It is written as `Ellipsis` or `...`.

## The NotImplemented Object

This object is returned from comparisons and binary operations when they are asked to operate on types they don't support. See [Comparisons](#) for more information. There is exactly one `NotImplemented` object. `type(NotImplemented)()` produces the singleton instance.

It is written as `NotImplemented`.

## Boolean Values

Boolean values are the two constant objects `False` and `True`. They are used to represent truth values (although other values can also be considered false or true). In numeric contexts (for example when used as the argument to an arithmetic operator), they behave like the integers 0 and 1, respectively. The built-in function `bool()` can be used to convert any value to a Boolean, if the value can be interpreted as a truth value (see section [Truth Value Testing](#) above).

They are written as `False` and `True`, respectively.

## Internal Objects

See [The standard type hierarchy](#) for this information. It describes stack frame objects, traceback objects, and slice objects.

## Special Attributes

The implementation adds a few special read-only attributes to several object types, where they are relevant. Some of these are not reported by the `dir()` built-in function.

`object.__dict__`

A dictionary or other mapping object used to store an object's (writable) attributes.

`instance.__class__`

The class to which a class instance belongs.

`class.__bases__`

The tuple of base classes of a class object.

`definition.__name__`

The name of the class, function, method, descriptor, or generator instance.

`definition.__qualname__`

The **qualified name** of the class, function, method, descriptor, or generator instance.

*New in version 3.3.*

`class.__mro__`

This attribute is a tuple of classes that are considered when looking for base classes during method resolution.

`class.mro()`

This method can be overridden by a metaclass to customize the method resolution order for its instances. It is called at class instantiation, and its result is stored in `__mro__`.

`class.__subclasses__()`

Each class keeps a list of weak references to its immediate subclasses. This method returns a list of all those references still alive. The list is in definition order. Example:

```
>>> int.__subclasses__()
[<class 'bool'>]
```

# Integer string conversion length limitation

CPython has a global limit for converting between `int` and `str` to mitigate denial of service attacks. This limit *only* applies to decimal or other non-power-of-two number bases. Hexadecimal, octal, and binary conversions are unlimited. The limit can be configured.

The `int` type in CPython is an arbitrary length number stored in binary form (commonly known as a “bignum”). There exists no algorithm that can convert a string to a binary integer or a binary integer to a string in linear time, *unless* the base is a power of 2. Even the best known algorithms for base 10 have sub-quadratic complexity. Converting a large value such as `int('1' * 500_000)` can take over a second on a fast CPU.

Limiting conversion size offers a practical way to avoid [CVE-2020-10735](https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-10735) [https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2020-10735].

The limit is applied to the number of digit characters in the input or output string when a non-linear conversion algorithm would be involved. Underscores and the sign are not counted towards the limit.

When an operation would exceed the limit, a `ValueError` is raised:

```
>>> import sys
>>> sys.set_int_max_str_digits(4300) # Illustrative, th
>>> _ = int('2' * 5432)
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer
>>> i = int('2' * 4300)
>>> len(str(i))
4300
>>> i_squared = i*i
>>> len(str(i_squared))
```

```
Traceback (most recent call last):
```

```
...
```

```
ValueError: Exceeds the limit (4300 digits) for integer
```

```
>>> len(hex(i_squared))
```

```
7144
```

```
>>> assert int(hex(i_squared), base=16) == i*i # Hexade
```

The default limit is 4300 digits as provided in

[`sys.int\_info.default\_max\_str\_digits`](#). The lowest limit that can be configured is 640 digits as provided in

[`sys.int\_info.str\_digits\_check\_threshold`](#).

Verification:

```
>>> import sys
```

```
>>> assert sys.int_info.default_max_str_digits == 4300,
```

```
>>> assert sys.int_info.str_digits_check_threshold == 640,
```

```
>>> msg = int('57896629371068288688099403514687379839672
```

```
...          '92529255143839154833338127435805497794361
```

```
...          '571186405732').to_bytes(53, 'big')
```

```
...
```

*New in version 3.11.*

## Affected APIs

The limitation only applies to potentially slow conversions between [`int`](#) and [`str`](#) or [`bytes`](#):

- `int(string)` with default base 10.
- `int(string, base)` for all bases that are not a power of 2.
- `str(integer)`.
- `repr(integer)`.
- any other string conversion to base 10, for example `f"{integer}"`, `"{}".format(integer)`, or `b"%d" % integer`.

The limitations do not apply to functions with a linear algorithm:

- `int(string, base)` with base 2, 4, 8, 16, or 32.

- `int.from_bytes()` and `int.to_bytes()`.
- `hex()`, `oct()`, `bin()`.
- Format Specification Mini-Language for hex, octal, and binary numbers.
- `str` to `float`.
- `str` to `decimal.Decimal`.

## Configuring the limit

Before Python starts up you can use an environment variable or an interpreter command line flag to configure the limit:

- **PYTHONINTMAXSTRDIGITS**, e.g.  
`PYTHONINTMAXSTRDIGITS=640 python3` to set the limit to 640 or `PYTHONINTMAXSTRDIGITS=0 python3` to disable the limitation.
- **-X int\_max\_str\_digits**, e.g. `python3 -X int_max_str_digits=640`
- **sys.flags.int\_max\_str\_digits** contains the value of **PYTHONINTMAXSTRDIGITS** or **-X int\_max\_str\_digits**. If both the env var and the **-X** option are set, the **-X** option takes precedence. A value of **-1** indicates that both were unset, thus a value of **sys.int\_info.default\_max\_str\_digits** was used during initialization.

From code, you can inspect the current limit and set a new one using these **sys** APIs:

- **sys.get\_int\_max\_str\_digits()** and **sys.set\_int\_max\_str\_digits()** are a getter and setter for the interpreter-wide limit. Subinterpreters have their own limit.

Information about the default and minimum can be found in **sys.int\_info**:

- **sys.int\_info.default\_max\_str\_digits** is the compiled-in default limit.
- **sys.int\_info.str\_digits\_check\_threshold** is the lowest accepted value for the limit (other than 0 which

disables it).

*New in version 3.11.*

## Caution

Setting a low limit *can* lead to problems. While rare, code exists that contains integer constants in decimal in their source that exceed the minimum threshold. A consequence of setting the limit is that Python source code containing decimal integer literals longer than the limit will encounter an error during parsing, usually at startup time or import time or even at installation time - anytime an up to date `.pyc` does not already exist for the code. A workaround for source that contains such large constants is to convert them to `0x` hexadecimal form as it has no limit.

Test your application thoroughly if you use a low limit. Ensure your tests run with the limit set early via the environment or flag so that it applies during startup and even during any installation step that may invoke Python to precompile `.py` sources to `.pyc` files.

## Recommended configuration

The default `sys.int_info.default_max_str_digits` is expected to be reasonable for most applications. If your application requires a different limit, set it from your main entry point using Python version agnostic code as these APIs were added in security patch releases in versions before 3.11.

Example:

```
>>> import sys
>>> if hasattr(sys, "set_int_max_str_digits"):
...     upper_bound = 68000
...     lower_bound = 4004
...     current_limit = sys.get_int_max_str_digits()
...     if current_limit == 0 or current_limit > upper_b
```

```
...         sys.set_int_max_str_digits(upper_bound)
...     elif current_limit < lower_bound:
...         sys.set_int_max_str_digits(lower_bound)
```

If you need to disable it entirely, set it to 0.

## Footnotes

1

Additional information on these special methods may be found in the Python Reference Manual ([Basic customization](#)).

2

As a consequence, the list `[1, 2]` is considered equal to `[1.0, 2.0]`, and similarly for tuples.

3

They must have since the parser can't tell the type of the operands.

4([1](#),[2](#),[3](#),[4](#))

Cased characters are those with general category property being one of “Lu” (Letter, uppercase), “Ll” (Letter, lowercase), or “Lt” (Letter, titlecase).

5([1](#),[2](#))

To format only a tuple you should therefore provide a singleton tuple whose only element is the tuple to be formatted.

# Built-in Exceptions

In Python, all exceptions must be instances of a class that derives from `BaseException`. In a `try` statement with an `except` clause that mentions a particular class, that clause also handles any exception classes derived from that class (but not exception classes from which *it* is derived). Two exception classes that are not related via subclassing are never equivalent, even if they have the same name.

The built-in exceptions listed below can be generated by the interpreter or built-in functions. Except where mentioned, they have an “associated value” indicating the detailed cause of the error. This may be a string or a tuple of several items of information (e.g., an error code and a string explaining the code). The associated value is usually passed as arguments to the exception class’s constructor.

User code can raise built-in exceptions. This can be used to test an exception handler or to report an error condition “just like” the situation in which the interpreter raises the same exception; but beware that there is nothing to prevent user code from raising an inappropriate error.

The built-in exception classes can be subclassed to define new exceptions; programmers are encouraged to derive new exceptions from the `Exception` class or one of its subclasses, and not from `BaseException`. More information on defining exceptions is available in the Python Tutorial under [User-defined Exceptions](#).

## Exception context

When raising a new exception while another exception is already being handled, the new exception’s `__context__` attribute is automatically set to the handled exception. An exception may be handled when an `except` or `finally` clause, or a `with` statement, is used.

This implicit exception context can be supplemented with an explicit cause by using **from** with **raise**:

```
raise new_exc from original_exc
```

The expression following **from** must be an exception or `None`. It will be set as `__cause__` on the raised exception. Setting `__cause__` also implicitly sets the `__suppress_context__` attribute to `True`, so that using `raise new_exc from None` effectively replaces the old exception with the new one for display purposes (e.g. converting `KeyError` to `AttributeError`), while leaving the old exception available in `__context__` for introspection when debugging.

The default traceback display code shows these chained exceptions in addition to the traceback for the exception itself. An explicitly chained exception in `__cause__` is always shown when present. An implicitly chained exception in `__context__` is shown only if `__cause__` is `None` and `__suppress_context__` is false.

In either case, the exception itself is always shown after any chained exceptions so that the final line of the traceback always shows the last exception that was raised.

## Inheriting from built-in exceptions

User code can create subclasses that inherit from an exception type. It's recommended to only subclass one exception type at a time to avoid any possible conflicts between how the bases handle the `args` attribute, as well as due to possible memory layout incompatibilities.

**CPython implementation detail:** Most built-in exceptions are implemented in C for efficiency, see: [Objects/exceptions.c](https://github.com/python/cpython/tree/3.11/Objects/exceptions.c) [https://github.com/python/cpython/tree/3.11/Objects/exceptions.c]. Some have custom memory layouts which makes it impossible to create a subclass that inherits from multiple exception types. The memory layout of a type is an implementation detail and might change between Python versions, leading to new conflicts in the future. Therefore, it's recommended to avoid subclassing multiple

exception types altogether.

## Base classes

The following exceptions are used mostly as base classes for other exceptions.

*exception* `BaseException`

The base class for all built-in exceptions. It is not meant to be directly inherited by user-defined classes (for that, use `Exception`). If `str()` is called on an instance of this class, the representation of the argument(s) to the instance are returned, or the empty string when there were no arguments.

`args`

The tuple of arguments given to the exception constructor. Some built-in exceptions (like `OSError`) expect a certain number of arguments and assign a special meaning to the elements of this tuple, while others are usually called only with a single string giving an error message.

`with_traceback(tb)`

This method sets *tb* as the new traceback for the exception and returns the exception object. It was more commonly used before the exception chaining features of [PEP 3134](https://peps.python.org/pep-3134/) [https://peps.python.org/pep-3134/] became available. The following example shows how we can convert an instance of `SomeException` into an instance of `OtherException` while preserving the traceback. Once raised, the current frame is pushed onto the traceback of the `OtherException`, as would have happened to the traceback of the original `SomeException` had we allowed it to propagate to the caller.

```
try:
    ...
except SomeException:
```

```
tb = sys.exception().__traceback__  
raise OtherException(...).with_traceback(tb)
```

`add_note(note)`

Add the string `note` to the exception's notes which appear in the standard traceback after the exception string. A **`TypeError`** is raised if `note` is not a string.

*New in version 3.11.*

`_notes_`

A list of the notes of this exception, which were added with `add_note()`. This attribute is created when `add_note()` is called.

*New in version 3.11.*

*exception* **Exception**

All built-in, non-system-exiting exceptions are derived from this class. All user-defined exceptions should also be derived from this class.

*exception* **ArithmeticError**

The base class for those built-in exceptions that are raised for various arithmetic errors: **`OverflowError`**, **`ZeroDivisionError`**, **`FloatingPointError`**.

*exception* **BufferError**

Raised when a **`buffer`** related operation cannot be performed.

*exception* **LookupError**

The base class for the exceptions that are raised when a key or index used on a mapping or sequence is invalid: **`IndexError`**, **`KeyError`**. This can be raised directly by `codecs.lookup()`.

## Concrete exceptions

The following exceptions are the exceptions that are usually raised.

*exception* `AssertionError`

Raised when an `assert` statement fails.

*exception* `AttributeError`

Raised when an attribute reference (see [Attribute references](#)) or assignment fails. (When an object does not support attribute references or attribute assignments at all, `TypeError` is raised.)

The `name` and `obj` attributes can be set using keyword-only arguments to the constructor. When set they represent the name of the attribute that was attempted to be accessed and the object that was accessed for said attribute, respectively.

*Changed in version 3.10:* Added the `name` and `obj` attributes.

*exception* `EOFError`

Raised when the `input()` function hits an end-of-file condition (EOF) without reading any data. (N.B.: the `io.IOBase.read()` and `io.IOBase.readline()` methods return an empty string when they hit EOF.)

*exception* `FloatingPointError`

Not currently used.

*exception* `GeneratorExit`

Raised when a [generator](#) or [coroutine](#) is closed; see `generator.close()` and `coroutine.close()`. It directly inherits from `BaseException` instead of `Exception` since it is technically not an error.

*exception* `ImportError`

Raised when the `import` statement has troubles trying to load a module. Also raised when the “from list” in `from ... import` has a name that cannot be found.

The `name` and `path` attributes can be set using keyword-

only arguments to the constructor. When set they represent the name of the module that was attempted to be imported and the path to any file which triggered the exception, respectively.

*Changed in version 3.3:* Added the **name** and **path** attributes.

#### *exception* ModuleNotFoundError

A subclass of **ImportError** which is raised by **import** when a module could not be located. It is also raised when **None** is found in **sys.modules**.

*New in version 3.6.*

#### *exception* IndexError

Raised when a sequence subscript is out of range. (Slice indices are silently truncated to fall in the allowed range; if an index is not an integer, **TypeError** is raised.)

#### *exception* KeyError

Raised when a mapping (dictionary) key is not found in the set of existing keys.

#### *exception* KeyboardInterrupt

Raised when the user hits the interrupt key (normally Control-C or Delete). During execution, a check for interrupts is made regularly. The exception inherits from **BaseException** so as to not be accidentally caught by code that catches **Exception** and thus prevent the interpreter from exiting.

### **Note**

Catching a **KeyboardInterrupt** requires special consideration. Because it can be raised at unpredictable points, it may, in some circumstances, leave the running program in an inconsistent state. It is generally best to allow **KeyboardInterrupt** to end the program as quickly as possible or avoid raising it entirely. (See [Note](#)

## on Signal Handlers and Exceptions.)

### *exception* MemoryError

Raised when an operation runs out of memory but the situation may still be rescued (by deleting some objects). The associated value is a string indicating what kind of (internal) operation ran out of memory. Note that because of the underlying memory management architecture (C's **malloc()** function), the interpreter may not always be able to completely recover from this situation; it nevertheless raises an exception so that a stack traceback can be printed, in case a run-away program was the cause.

### *exception* NameError

Raised when a local or global name is not found. This applies only to unqualified names. The associated value is an error message that includes the name that could not be found.

The **name** attribute can be set using a keyword-only argument to the constructor. When set it represent the name of the variable that was attempted to be accessed.

*Changed in version 3.10:* Added the **name** attribute.

### *exception* NotImplementedError

This exception is derived from **RuntimeError**. In user defined base classes, abstract methods should raise this exception when they require derived classes to override the method, or while the class is being developed to indicate that the real implementation still needs to be added.

### **Note**

It should not be used to indicate that an operator or method is not meant to be supported at all – in that case either leave the operator / method undefined or, if a subclass, set it to **None**.

## Note

`NotImplementedError` and `NotImplemented` are not interchangeable, even though they have similar names and purposes. See [NotImplemented](#) for details on when to use it.

*exception* `OSError([arg])`

*exception* `OSError(errno, strerror[, filename[, winerror[, filename2]]])`

This exception is raised when a system function returns a system-related error, including I/O failures such as “file not found” or “disk full” (not for illegal argument types or other incidental errors).

The second form of the constructor sets the corresponding attributes, described below. The attributes default to `None` if not specified. For backwards compatibility, if three arguments are passed, the `args` attribute contains only a 2-tuple of the first two constructor arguments.

The constructor often actually returns a subclass of `OSError`, as described in [OS exceptions](#) below. The particular subclass depends on the final `errno` value. This behaviour only occurs when constructing `OSError` directly or via an alias, and is not inherited when subclassing.

`errno`

A numeric error code from the C variable `errno`.

`winerror`

Under Windows, this gives you the native Windows error code. The `errno` attribute is then an approximate translation, in POSIX terms, of that native error code.

Under Windows, if the `winerror` constructor argument is an integer, the `errno` attribute is determined from the

Windows error code, and the *errno* argument is ignored. On other platforms, the *winerror* argument is ignored, and the `winerror` attribute does not exist.

`strerror`

The corresponding error message, as provided by the operating system. It is formatted by the C functions `perror()` under POSIX, and `FormatMessage()` under Windows.

`filename`

`filename2`

For exceptions that involve a file system path (such as `open()` or `os.unlink()`), `filename` is the file name passed to the function. For functions that involve two file system paths (such as `os.rename()`), `filename2` corresponds to the second file name passed to the function.

*Changed in version 3.3:* `EnvironmentError`, `IOError`, `WindowsError`, `socket.error`, `select.error` and `mmap.error` have been merged into `OSError`, and the constructor may return a subclass.

*Changed in version 3.4:* The `filename` attribute is now the original file name passed to the function, instead of the name encoded to or decoded from the `filesystem encoding and error handler`. Also, the `filename2` constructor argument and attribute was added.

*exception* `OverflowError`

Raised when the result of an arithmetic operation is too large to be represented. This cannot occur for integers (which would rather raise `MemoryError` than give up). However, for historical reasons, `OverflowError` is sometimes raised for integers that are outside a required range. Because of the lack of standardization of floating point exception handling in C, most floating point operations are not checked.

### *exception* RecursionError

This exception is derived from `RuntimeError`. It is raised when the interpreter detects that the maximum recursion depth (see `sys.getrecursionlimit()`) is exceeded.

*New in version 3.5:* Previously, a plain `RuntimeError` was raised.

### *exception* ReferenceError

This exception is raised when a weak reference proxy, created by the `weakref.proxy()` function, is used to access an attribute of the referent after it has been garbage collected. For more information on weak references, see the `weakref` module.

### *exception* RuntimeError

Raised when an error is detected that doesn't fall in any of the other categories. The associated value is a string indicating what precisely went wrong.

### *exception* StopIteration

Raised by built-in function `next()` and an `iterator`'s `__next__()` method to signal that there are no further items produced by the iterator.

The exception object has a single attribute `value`, which is given as an argument when constructing the exception, and defaults to `None`.

When a `generator` or `coroutine` function returns, a new `StopIteration` instance is raised, and the value returned by the function is used as the `value` parameter to the constructor of the exception.

If a generator code directly or indirectly raises `StopIteration`, it is converted into a `RuntimeError` (retaining the `StopIteration` as the new exception's cause).

*Changed in version 3.3:* Added `value` attribute and the ability for generator functions to use it to return a value.

*Changed in version 3.5:* Introduced the `RuntimeError` transformation via `from __future__ import generator_stop`, see [PEP 479](https://peps.python.org/pep-0479/) [https://peps.python.org/pep-0479/].

*Changed in version 3.7:* Enable [PEP 479](https://peps.python.org/pep-0479/) [https://peps.python.org/pep-0479/] for all code by default: a `StopIteration` error raised in a generator is transformed into a `RuntimeError`.

*exception* `StopAsyncIteration`

Must be raised by `__anext__()` method of an `asynchronous iterator` object to stop the iteration.

*New in version 3.5.*

*exception* `SyntaxError(message, details)`

Raised when the parser encounters a syntax error. This may occur in an `import` statement, in a call to the built-in functions `compile()`, `exec()`, or `eval()`, or when reading the initial script or standard input (also interactively).

The `str()` of the exception instance returns only the error message. `Details` is a tuple whose members are also available as separate attributes.

`filename`

The name of the file the syntax error occurred in.

`lineno`

Which line number in the file the error occurred in. This is 1-indexed: the first line in the file has a `lineno` of 1.

`offset`

The column in the line where the error occurred. This is 1-indexed: the first character in the line has an

`offset` of 1.

`text`

The source code text involved in the error.

`end_lineno`

Which line number in the file the error occurred ends in. This is 1-indexed: the first line in the file has a `lineno` of 1.

`end_offset`

The column in the end line where the error occurred finishes. This is 1-indexed: the first character in the line has an `offset` of 1.

For errors in f-string fields, the message is prefixed by “f-string: ” and the offsets are offsets in a text constructed from the replacement expression. For example, compiling `f'Bad {a b} field'` results in this `args` attribute: `('f-string: ...', ('', 1, 2, '(a b)n', 1, 5))`.

*Changed in version 3.10:* Added the `end_lineno` and `end_offset` attributes.

*exception* `IndentationError`

Base class for syntax errors related to incorrect indentation. This is a subclass of `SyntaxError`.

*exception* `TabError`

Raised when indentation contains an inconsistent use of tabs and spaces. This is a subclass of `IndentationError`.

*exception* `SystemError`

Raised when the interpreter finds an internal error, but the situation does not look so serious to cause it to abandon all hope. The associated value is a string indicating what went wrong (in low-level terms).

You should report this to the author or maintainer of your Python interpreter. Be sure to report the version of the Python interpreter (`sys.version`; it is also printed at the start of an interactive Python session), the exact error message (the exception's associated value) and if possible the source of the program that triggered the error.

### *exception* `SystemExit`

This exception is raised by the `sys.exit()` function. It inherits from `BaseException` instead of `Exception` so that it is not accidentally caught by code that catches `Exception`. This allows the exception to properly propagate up and cause the interpreter to exit. When it is not handled, the Python interpreter exits; no stack traceback is printed. The constructor accepts the same optional argument passed to `sys.exit()`. If the value is an integer, it specifies the system exit status (passed to C's `exit()` function); if it is `None`, the exit status is zero; if it has another type (such as a string), the object's value is printed and the exit status is one.

A call to `sys.exit()` is translated into an exception so that clean-up handlers (`finally` clauses of `try` statements) can be executed, and so that a debugger can execute a script without running the risk of losing control. The `os._exit()` function can be used if it is absolutely positively necessary to exit immediately (for example, in the child process after a call to `os.fork()`).

code

The exit status or error message that is passed to the constructor. (Defaults to `None`.)

### *exception* `TypeError`

Raised when an operation or function is applied to an object of inappropriate type. The associated value is a string giving details about the type mismatch.

This exception may be raised by user code to indicate that an attempted operation on an object is not supported, and is not

meant to be. If an object is meant to support a given operation but has not yet provided an implementation, **NotImplementedError** is the proper exception to raise.

Passing arguments of the wrong type (e.g. passing a **list** when an **int** is expected) should result in a **TypeError**, but passing arguments with the wrong value (e.g. a number outside expected boundaries) should result in a **ValueError**.

#### *exception* UnboundLocalError

Raised when a reference is made to a local variable in a function or method, but no value has been bound to that variable. This is a subclass of **NameError**.

#### *exception* UnicodeError

Raised when a Unicode-related encoding or decoding error occurs. It is a subclass of **ValueError**.

**UnicodeError** has attributes that describe the encoding or decoding error. For example, `err.object[err.start:err.end]` gives the particular invalid input that the codec failed on.

#### encoding

The name of the encoding that raised the error.

#### reason

A string describing the specific codec error.

#### object

The object the codec was attempting to encode or decode.

#### start

The first index of invalid data in **object**.

#### end

The index after the last invalid data in `object`.

*exception* `UnicodeEncodeError`

Raised when a Unicode-related error occurs during encoding. It is a subclass of `UnicodeError`.

*exception* `UnicodeDecodeError`

Raised when a Unicode-related error occurs during decoding. It is a subclass of `UnicodeError`.

*exception* `UnicodeTranslateError`

Raised when a Unicode-related error occurs during translating. It is a subclass of `UnicodeError`.

*exception* `ValueError`

Raised when an operation or function receives an argument that has the right type but an inappropriate value, and the situation is not described by a more precise exception such as `IndexError`.

*exception* `ZeroDivisionError`

Raised when the second argument of a division or modulo operation is zero. The associated value is a string indicating the type of the operands and the operation.

The following exceptions are kept for compatibility with previous versions; starting from Python 3.3, they are aliases of `OSError`.

*exception* `EnvironmentError`

*exception* `IOError`

*exception* `WindowsError`

Only available on Windows.

## OS exceptions

The following exceptions are subclasses of **OSError**, they get raised depending on the system error code.

*exception* **BlockingIOError**

Raised when an operation would block on an object (e.g. socket) set for non-blocking operation. Corresponds to **errno** **EAGAIN**, **EALREADY**, **EWOULDBLOCK** and **EINPROGRESS**.

In addition to those of **OSError**, **BlockingIOError** can have one more attribute:

**characters\_written**

An integer containing the number of characters written to the stream before it blocked. This attribute is available when using the buffered I/O classes from the **io** module.

*exception* **ChildProcessError**

Raised when an operation on a child process failed. Corresponds to **errno** **ECHILD**.

*exception* **ConnectionError**

A base class for connection-related issues.

Subclasses are **BrokenPipeError**, **ConnectionAbortedError**, **ConnectionRefusedError** and **ConnectionResetError**.

*exception* **BrokenPipeError**

A subclass of **ConnectionError**, raised when trying to write on a pipe while the other end has been closed, or trying to write on a socket which has been shutdown for writing. Corresponds to **errno** **EPIPE** and **ESHUTDOWN**.

*exception* **ConnectionAbortedError**

A subclass of **ConnectionError**, raised when a connection attempt is aborted by the peer. Corresponds to **errno** **ECONNABORTED**.

*exception* `ConnectionRefusedError`

A subclass of `ConnectionError`, raised when a connection attempt is refused by the peer. Corresponds to `errno ECONNREFUSED`.

*exception* `ConnectionResetError`

A subclass of `ConnectionError`, raised when a connection is reset by the peer. Corresponds to `errno ECONNRESET`.

*exception* `FileExistsError`

Raised when trying to create a file or directory which already exists. Corresponds to `errno EEXIST`.

*exception* `FileNotFoundError`

Raised when a file or directory is requested but doesn't exist. Corresponds to `errno ENOENT`.

*exception* `InterruptedError`

Raised when a system call is interrupted by an incoming signal. Corresponds to `errno EINTR`.

*Changed in version 3.5:* Python now retries system calls when a syscall is interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale), instead of raising `InterruptedError`.

*exception* `IsADirectoryError`

Raised when a file operation (such as `os.remove()`) is requested on a directory. Corresponds to `errno EISDIR`.

*exception* `NotADirectoryError`

Raised when a directory operation (such as `os.listdir()`) is requested on something which is not a directory. On most POSIX platforms, it may also be raised if an operation attempts to open or traverse a non-directory file as if it were a directory. Corresponds to `errno ENOTDIR`.

### *exception* `PermissionError`

Raised when trying to run an operation without the adequate access rights - for example filesystem permissions.

Corresponds to `errno` `EACCES`, `EPERM`, and `ENOTCAPABLE`.

*Changed in version 3.11.1:* WASI's `ENOTCAPABLE` is now mapped to `PermissionError`.

### *exception* `ProcessLookupError`

Raised when a given process doesn't exist. Corresponds to `errno` `ESRCH`.

### *exception* `TimeoutError`

Raised when a system function timed out at the system level. Corresponds to `errno` `ETIMEDOUT`.

*New in version 3.3:* All the above `OSError` subclasses were added.

## Warnings

The following exceptions are used as warning categories; see the [Warning Categories](#) documentation for more details.

### *exception* `Warning`

Base class for warning categories.

### *exception* `UserWarning`

Base class for warnings generated by user code.

### *exception* `DeprecationWarning`

Base class for warnings about deprecated features when those

warnings are intended for other Python developers.

Ignored by the default warning filters, except in the `__main__` module ([PEP 565](https://peps.python.org/pep-0565/) [https://peps.python.org/pep-0565/]). Enabling the [Python Development Mode](#) shows this warning.

The deprecation policy is described in [PEP 387](https://peps.python.org/pep-0387/) [https://peps.python.org/pep-0387/].

### *exception PendingDeprecationWarning*

Base class for warnings about features which are obsolete and expected to be deprecated in the future, but are not deprecated at the moment.

This class is rarely used as emitting a warning about a possible upcoming deprecation is unusual, and [DeprecationWarning](#) is preferred for already active deprecations.

Ignored by the default warning filters. Enabling the [Python Development Mode](#) shows this warning.

The deprecation policy is described in [PEP 387](https://peps.python.org/pep-0387/) [https://peps.python.org/pep-0387/].

### *exception SyntaxWarning*

Base class for warnings about dubious syntax.

### *exception RuntimeWarning*

Base class for warnings about dubious runtime behavior.

### *exception FutureWarning*

Base class for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.

### *exception ImportWarning*

Base class for warnings about probable mistakes in module imports.

Ignored by the default warning filters. Enabling the [Python Development Mode](#) shows this warning.

*exception* `UnicodeWarning`

Base class for warnings related to Unicode.

*exception* `EncodingWarning`

Base class for warnings related to encodings.

See [Opt-in EncodingWarning](#) for details.

*New in version 3.10.*

*exception* `BytesWarning`

Base class for warnings related to [bytes](#) and [bytearray](#).

*exception* `ResourceWarning`

Base class for warnings related to resource usage.

Ignored by the default warning filters. Enabling the [Python Development Mode](#) shows this warning.

*New in version 3.2.*

## Exception groups

The following are used when it is necessary to raise multiple unrelated exceptions. They are part of the exception hierarchy so they can be handled with [except](#) like all other exceptions. In addition, they are recognised by [except\\*](#), which matches their subgroups based on the types of the contained exceptions.

*exception* `ExceptionGroup(msg, excs)`

*exception* `BaseExceptionGroup(msg, excs)`

Both of these exception types wrap the exceptions in the sequence `excs`. The `msg` parameter must be a string. The difference between the two classes is that

`BaseExceptionGroup` extends `BaseException` and it can wrap any exception, while `ExceptionGroup` extends `Exception` and it can only wrap subclasses of `Exception`. This design is so that `except Exception` catches an `ExceptionGroup` but not `BaseExceptionGroup`.

The `BaseExceptionGroup` constructor returns an `ExceptionGroup` rather than a `BaseExceptionGroup` if all contained exceptions are `Exception` instances, so it can be used to make the selection automatic. The `ExceptionGroup` constructor, on the other hand, raises a `TypeError` if any contained exception is not an `Exception` subclass.

message

The `msg` argument to the constructor. This is a read-only attribute.

exceptions

A tuple of the exceptions in the `excs` sequence given to the constructor. This is a read-only attribute.

subgroup(*condition*)

Returns an exception group that contains only the exceptions from the current group that match *condition*, or `None` if the result is empty.

The condition can be either a function that accepts an exception and returns true for those that should be in the subgroup, or it can be an exception type or a tuple of exception types, which is used to check for a match using the same check that is used in an `except` clause.

The nesting structure of the current exception is preserved in the result, as are the values of its `message`, `__traceback__`, `__cause__`, `__context__` and `__notes__` fields. Empty nested groups are omitted from the result.

The condition is checked for all exceptions in the

nested exception group, including the top-level and any nested exception groups. If the condition is true for such an exception group, it is included in the result in full.

### `split(condition)`

Like `subgroup()`, but returns the pair `(match, rest)` where `match` is `subgroup(condition)` and `rest` is the remaining non-matching part.

### `derive(excs)`

Returns an exception group with the same `message`, but which wraps the exceptions in `excs`.

This method is used by `subgroup()` and `split()`. A subclass needs to override it in order to make `subgroup()` and `split()` return instances of the subclass rather than `ExceptionGroup`.

`subgroup()` and `split()` copy the `__traceback__`, `__cause__`, `__context__` and `__notes__` fields from the original exception group to the one returned by `derive()`, so these fields do not need to be updated by `derive()`.

```
>>> class MyGroup(ExceptionGroup):
...     def derive(self, excs):
...         return MyGroup(self.message, excs)
...
>>> e = MyGroup("eg", [ValueError(1), TypeError(2)])
>>> e.add_note("a note")
>>> e.__context__ = Exception("context")
>>> e.__cause__ = Exception("cause")
>>> try:
...     raise e
... except Exception as e:
...     exc = e
...
>>> match, rest = exc.split(ValueError)
```

```
>>> exc, exc.__context__, exc.__cause__, exc.__
(MyGroup('eg', [ValueError(1), TypeError(2)]),
>>> match, match.__context__, match.__cause__,
(MyGroup('eg', [ValueError(1)]), Exception('con
>>> rest, rest.__context__, rest.__cause__, res
(MyGroup('eg', [TypeError(2)]), Exception('cont
>>> exc.__traceback__ is match.__traceback__ is
True
```

Note that `BaseExceptionGroup` defines `__new__()`, so subclasses that need a different constructor signature need to override that rather than `__init__()`. For example, the following defines an exception group subclass which accepts an `exit_code` and constructs the group's message from it.

```
class Errors(ExceptionGroup):
    def __new__(cls, errors, exit_code):
        self = super().__new__(Errors, f"exit code: {
        self.exit_code = exit_code
        return self

    def derive(self, excs):
        return Errors(excs, self.exit_code)
```

Like `ExceptionGroup`, any subclass of `BaseExceptionGroup` which is also a subclass of `Exception` can only wrap instances of `Exception`.

*New in version 3.11.*

## Exception hierarchy

The class hierarchy for built-in exceptions is:

```
BaseException
  BaseExceptionGroup
  GeneratorExit
  KeyboardInterrupt
  SystemExit
```

[String Methods](#)

## String constants

The constants defined in this module are:

`string.ascii_letters`

The concatenation of the [ascii\\_lowercase](#) and [ascii\\_uppercase](#) constants described below. This value is not locale-dependent.

`string.ascii_lowercase`

The lowercase letters `'abcdefghijklmnopqrstuvwxyz'`. This value is not locale-dependent and will not change.

`string.ascii_uppercase`

The uppercase letters `'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. This value is not locale-dependent and will not change.

`string.digits`

The string `'0123456789'`.

`string.hexdigits`

The string `'0123456789abcdefABCDEF'`.

`string.octdigits`

The string `'01234567'`.

`string.punctuation`

String of ASCII characters which are considered punctuation characters in the C locale: `!"#$%&'()*+,-./:;<=>?@[\]^_`{|}~.`

`string.printable`

String of ASCII characters which are considered printable. This is a combination of `digits`, `ascii_letters`, `punctuation`, and `whitespace`.

`string.whitespace`

A string containing all ASCII characters that are considered whitespace. This includes the characters space, tab, linefeed, return, formfeed, and vertical tab.

## Custom String Formatting

The built-in string class provides the ability to do complex variable substitutions and value formatting via the `format()` method described in [PEP 3101](https://peps.python.org/pep-3101/) [https://peps.python.org/pep-3101/]. The `Formatter` class in the `string` module allows you to create and customize your own string formatting behaviors using the same implementation as the built-in `format()` method.

`class string.Formatter`

The `Formatter` class has the following public methods:

`format(format_string, /, *args, **kwargs)`

The primary API method. It takes a format string and an arbitrary set of positional and keyword arguments. It is just a wrapper that calls `vformat()`.

*Changed in version 3.7:* A format string argument is now **positional-only**.

`vformat(format_string, args, kwargs)`

This function does the actual work of formatting. It is exposed as a separate function for cases where you want to pass in a predefined dictionary of arguments, rather than unpacking and repacking the dictionary as individual arguments using the `*args` and `**kwargs` syntax. `vformat()` does the work of breaking up the format string into character data and replacement fields. It calls the various methods described below.

In addition, the `Formatter` defines a number of methods that are intended to be replaced by subclasses:

`parse(format_string)`

Loop over the `format_string` and return an iterable of tuples (*literal\_text*, *field\_name*, *format\_spec*, *conversion*). This is used by `vformat()` to break the string into either literal text, or replacement fields.

The values in the tuple conceptually represent a span of literal text followed by a single replacement field. If there is no literal text (which can happen if two replacement fields occur consecutively), then *literal\_text* will be a zero-length string. If there is no replacement field, then the values of *field\_name*, *format\_spec* and *conversion* will be `None`.

`get_field(field_name, args, kwargs)`

Given *field\_name* as returned by `parse()` (see above), convert it to an object to be formatted. Returns a tuple (obj, used\_key). The default version takes strings of the form defined in **PEP 3101** [<https://peps.python.org/pep-3101/>], such as “0[name]” or “label.title”. *args* and *kwargs* are as passed in to `vformat()`. The return value *used\_key* has the same meaning as the *key* parameter to `get_value()`.

`get_value(key, args, kwargs)`

Retrieve a given field value. The *key* argument will be either an integer or a string. If it is an integer, it represents the index of the positional argument in *args*; if it is a string, then it represents a named argument in *kwargs*.

The *args* parameter is set to the list of positional arguments to `vformat()`, and the *kwargs* parameter is set to the dictionary of keyword arguments.

For compound field names, these functions are only called for the first component of the field name; subsequent components are handled through normal attribute and indexing operations.

So for example, the field expression '0.name' would cause `get_value()` to be called with a *key* argument of 0. The `name` attribute will be looked up after `get_value()` returns by calling the built-in `getattr()` function.

If the index or keyword refers to an item that does not exist, then an `IndexError` or `KeyError` should be raised.

`check_unused_args(used_args, args, kwargs)`

Implement checking for unused arguments if desired. The arguments to this function is the set of all argument keys that were actually referred to in the format string (integers for positional arguments, and strings for named arguments), and a reference to the *args* and *kwargs* that was passed to `vformat`. The set of unused args can be calculated from these parameters. `check_unused_args()` is assumed to raise an exception if the check fails.

`format_field(value, format_spec)`

`format_field()` simply calls the global `format()`

built-in. The method is provided so that subclasses can override it.

`convert_field(value, conversion)`

Converts the value (returned by `get_field()`) given a conversion type (as in the tuple returned by the `parse()` method). The default version understands 's' (str), 'r' (repr) and 'a' (ascii) conversion types.

## Format String Syntax

The `str.format()` method and the `Formatter` class share the same syntax for format strings (although in the case of `Formatter`, subclasses can define their own format string syntax). The syntax is related to that of *formatted string literals*, but it is less sophisticated and, in particular, does not support arbitrary expressions.

Format strings contain “replacement fields” surrounded by curly braces `{}`. Anything that is not contained in braces is considered literal text, which is copied unchanged to the output. If you need to include a brace character in the literal text, it can be escaped by doubling: `{{` and `}}`.

The grammar for a replacement field is as follows:

```
replacement_field ::= "{" [field_name] ["!" conversion_spec] [format_spec]
field_name         ::= arg_name ("." attribute_name)
arg_name           ::= [identifier | digit+]
attribute_name     ::= identifier
element_index      ::= digit+ | index_string
index_string       ::= <any source character except "]">
conversion         ::= "r" | "s" | "a"
format_spec        ::= <described in the next section>
```

In less formal terms, the replacement field can start with a *field\_name* that specifies the object whose value is to be formatted and inserted into the output instead of the replacement field. The

*field\_name* is optionally followed by a *conversion* field, which is preceded by an exclamation point '!', and a *format\_spec*, which is preceded by a colon ':'. These specify a non-default format for the replacement value.

See also the [Format Specification Mini-Language](#) section.

The *field\_name* itself begins with an *arg\_name* that is either a number or a keyword. If it's a number, it refers to a positional argument, and if it's a keyword, it refers to a named keyword argument. An *arg\_name* is treated as a number if a call to `str.isdecimal()` on the string would return true. If the numerical *arg\_names* in a format string are 0, 1, 2, ... in sequence, they can all be omitted (not just some) and the numbers 0, 1, 2, ... will be automatically inserted in that order. Because *arg\_name* is not quote-delimited, it is not possible to specify arbitrary dictionary keys (e.g., the strings '10' or ':-]') within a format string. The *arg\_name* can be followed by any number of index or attribute expressions. An expression of the form '.name' selects the named attribute using `getattr()`, while an expression of the form '[index]' does an index lookup using `__getitem__()`.

*Changed in version 3.1:* The positional argument specifiers can be omitted for `str.format()`, so '{} {}'.format(a, b) is equivalent to '{0} {1}'.format(a, b).

*Changed in version 3.4:* The positional argument specifiers can be omitted for `Formatter`.

Some simple format string examples:

```
"First, thou shalt count to {0}" # References first positional argument
"Bring me a {}"                 # Implicitly reference first argument
"From {} to {}".format(1, 2)    # Same as "From {0} to {1}".format(1, 2)
"My quest is {name}"            # References keyword argument 'name'
"Weight in tons {0.weight}"      # 'weight' attribute of first argument
"Units destroyed: {players[0]}"  # First element of keyword argument 'players'
```

The *conversion* field causes a type coercion before formatting.

Normally, the job of formatting a value is done by the

`__format__()` method of the value itself. However, in some cases

it is desirable to force a type to be formatted as a string, overriding its own definition of formatting. By converting the value to a string before calling `__format__()`, the normal formatting logic is bypassed.

Three conversion flags are currently supported: `'!s'` which calls `str()` on the value, `'!r'` which calls `repr()` and `'!a'` which calls `ascii()`.

Some examples:

```
"Harold's a clever {0!s}"          # Calls str() on the argument
"Bring out the holy {name!r}"      # Calls repr() on the argument
"More {!a}"                        # Calls ascii() on the argument
```

The `format_spec` field contains a specification of how the value should be presented, including such details as field width, alignment, padding, decimal precision and so on. Each value type can define its own “formatting mini-language” or interpretation of the `format_spec`.

Most built-in types support a common formatting mini-language, which is described in the next section.

A `format_spec` field can also include nested replacement fields within it. These nested replacement fields may contain a field name, conversion flag and format specification, but deeper nesting is not allowed. The replacement fields within the `format_spec` are substituted before the `format_spec` string is interpreted. This allows the formatting of a value to be dynamically specified.

See the [Format examples](#) section for some examples.

## Format Specification Mini-Language

“Format specifications” are used within replacement fields contained within a format string to define how individual values are presented (see [Format String Syntax](#) and [Formatted string literals](#)). They can also be passed directly to the built-in `format()` function. Each formattable type may define how the format specification is to be interpreted.

Most built-in types implement the following options for format specifications, although some of the formatting options are only supported by the numeric types.

A general convention is that an empty format specification produces the same result as if you had called `str()` on the value. A non-empty format specification typically modifies the result.

The general form of a *standard format specifier* is:

```
format_spec      ::=  [[fill]align][sign]["z"]["#"]["0"]  
fill            ::=  <any character>  
align           ::=  "<" | ">" | "=" | "^"  
sign           ::=  "+" | "-" | " "  
width          ::=  digit+  
grouping_option ::=  "_" | ",",  
precision     ::=  digit+  
type           ::=  "b" | "c" | "d" | "e" | "E" | "f" |
```

If a valid *align* value is specified, it can be preceded by a *fill* character that can be any character and defaults to a space if omitted. It is not possible to use a literal curly brace (“{” or “}”) as the *fill* character in a [formatted string literal](#) or when using the `str.format()` method. However, it is possible to insert a curly brace with a nested replacement field. This limitation doesn’t affect the `format()` function.

The meaning of the various alignment options is as follows:

### **Optioning**

---

**F**orces the field to be left-aligned within the available space (this is the default for most objects).

---

**F**orces the field to be right-aligned within the available space (this is the default for numbers).

---

**F**orces the padding to be placed after the sign (if any) but before the digits. This is used for printing fields in the form ‘+000000120’. This alignment option is only valid for numeric types. It becomes the default for numbers when ‘0’

---

immediately precedes the field width.

~~Forces the field to be centered within the~~  
available space.

Note that unless a minimum field width is defined, the field width will always be the same size as the data to fill it, so that the alignment option has no meaning in this case.

The *sign* option is only valid for number types, and can be one of the following:

### **~~Optioning~~**

~~indicates that a sign should be used for both~~  
positive as well as negative numbers.

~~indicates that a sign should be used only for~~  
negative numbers (this is the default behavior).

~~indicates that a leading space should be used on~~  
positive numbers, and a minus sign on negative  
numbers.

The 'z' option coerces negative zero floating-point values to positive zero after rounding to the format precision. This option is only valid for floating-point presentation types.

*Changed in version 3.11:* Added the 'z' option (see also [PEP 682](https://peps.python.org/pep-0682/) [<https://peps.python.org/pep-0682/>]).

The '#' option causes the “alternate form” to be used for the conversion. The alternate form is defined differently for different types. This option is only valid for integer, float and complex types. For integers, when binary, octal, or hexadecimal output is used, this option adds the respective prefix '0b', '0o', '0x', or '0X' to the output value. For float and complex the alternate form causes the result of the conversion to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for 'g' and 'G' conversions, trailing zeros are not removed from the result.

The ',' option signals the use of a comma for a thousands separator. For a locale aware separator, use the 'n' integer

presentation type instead.

*Changed in version 3.1:* Added the `' , '` option (see also [PEP 378](https://peps.python.org/pep-0378/) [https://peps.python.org/pep-0378/]).

The `' _ '` option signals the use of an underscore for a thousands separator for floating point presentation types and for integer presentation type `' d '`. For integer presentation types `' b '`, `' o '`, `' x '`, and `' X '`, underscores will be inserted every 4 digits. For other presentation types, specifying this option is an error.

*Changed in version 3.6:* Added the `' _ '` option (see also [PEP 515](https://peps.python.org/pep-0515/) [https://peps.python.org/pep-0515/]).

*width* is a decimal integer defining the minimum total field width, including any prefixes, separators, and other formatting characters. If not specified, then the field width will be determined by the content.

When no explicit alignment is given, preceding the *width* field by a zero (`' 0 '`) character enables sign-aware zero-padding for numeric types. This is equivalent to a *fill* character of `' 0 '` with an *alignment* type of `' = '`.

*Changed in version 3.10:* Preceding the *width* field by `' 0 '` no longer affects the default alignment for strings.

The *precision* is a decimal integer indicating how many digits should be displayed after the decimal point for presentation types `' f '` and `' F '`, or before and after the decimal point for presentation types `' g '` or `' G '`. For string presentation types the field indicates the maximum field size - in other words, how many characters will be used from the field content. The *precision* is not allowed for integer presentation types.

Finally, the *type* determines how the data should be presented.

The available string presentation types are:

---

### **Meaning**

---

**String** format. This is the default type for strings and may be omitted.

---

~~None~~ same as 's'.

---

The available integer presentation types are:

**Meaning**

~~Binary~~ format. Outputs the number in base 2.

~~Character~~. Converts the integer to the corresponding unicode character before printing.

~~Decimal Integer~~. Outputs the number in base 10.

~~Octal~~ format. Outputs the number in base 8.

~~Hex~~ format. Outputs the number in base 16, using lower-case letters for the digits above 9.

~~Hex~~ format. Outputs the number in base 16, using upper-case letters for the digits above 9. In case '#' is specified, the prefix '0x' will be upper-cased to '0X' as well.

~~Number~~. This is the same as 'd', except that it uses the current locale setting to insert the appropriate number separator characters.

~~None~~ same as 'd'.

---

In addition to the above presentation types, integers can be formatted with the floating point presentation types listed below (except 'n' and `None`). When doing so, `float()` is used to convert the integer to a floating point number before formatting.

The available presentation types for `float` and `Decimal` values are:

**Meaning**

~~Scientific notation~~. For a given precision `p`, formats the number in scientific notation with the letter 'e' separating the coefficient from the exponent. The coefficient has one digit before and `p` digits after the decimal point, for a total of `p + 1` significant digits. With no precision given, uses a precision of 6 digits after the decimal point for `float`, and shows all coefficient digits for `Decimal`. If no digits follow the decimal point, the decimal point is also removed unless the `#` option is used.

---

**Scientific notation.** Same as 'e' except it uses an upper case 'E' as the separator character.

---

**Fixed-point notation.** For a given precision  $p$ , formats the number as a decimal number with exactly  $p$  digits following the decimal point. With no precision given, uses a precision of 6 digits after the decimal point for **float**, and uses a precision large enough to show all coefficient digits for **Decimal**. If no digits follow the decimal point, the decimal point is also removed unless the # option is used.

---

**Fixed-point notation.** Same as 'f', but converts nan to NAN and inf to INF.

---

**General format.** For a given precision  $p \geq 1$ , this rounds the number to  $p$  significant digits and then formats the result in either fixed-point format or in scientific notation, depending on its magnitude. A precision of 0 is treated as equivalent to a precision of 1.

The precise rules are as follows: suppose that the result formatted with presentation type 'e' and precision  $p-1$  would have exponent  $exp$ . Then, if  $m \leq exp < p$ , where  $m$  is -4 for floats and -6 for **Decimals**, the number is formatted with presentation type 'f' and precision  $p-1-exp$ . Otherwise, the number is formatted with presentation type 'e' and precision  $p-1$ . In both cases insignificant trailing zeros are removed from the significand, and the decimal point is also removed if there are no remaining digits following it, unless the '#' option is used.

With no precision given, uses a precision of 6 significant digits for **float**. For **Decimal**, the coefficient of the result is formed from the coefficient digits of the value; scientific notation is used for values smaller than  $1e-6$  in absolute value and values where the place value of the least significant digit is larger than 1, and fixed-point notation is used otherwise.

Positive and negative infinity, positive and negative zero, and nans, are formatted as `inf`, `-inf`, `0`, `-0` and `nan` respectively, regardless of the precision.

**General format.** Same as `'g'` except switches to `'E'` if the number gets too large. The representations of infinity and NaN are uppercased, too.

**Number.** This is the same as `'g'`, except that it uses the current locale setting to insert the appropriate number separator characters.

**Percentage.** Multiplies the number by 100 and displays in fixed (`'f'`) format, followed by a percent sign.

**Nonefloat** this is the same as `'g'`, except that when fixed-point notation is used to format the result, it always includes at least one digit past the decimal point. The precision used is as large as needed to represent the given value faithfully. For **Decimal**, this is the same as either `'g'` or `'G'` depending on the value of `context.capitals` for the current decimal context.

The overall effect is to match the output of **`str()`** as altered by the other format modifiers.

## Format examples

This section contains examples of the **`str.format()`** syntax and comparison with the old `%`-formatting.

In most of the cases the syntax is similar to the old `%`-formatting, with the addition of the `{}` and with `:` used instead of `%`. For example, `'%03.2f'` can be translated to `'{:03.2f}'`.

The new format syntax also supports new and different options, shown in the following examples.

Accessing arguments by position:

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{} , {} , {}'.format('a', 'b', 'c') # 3.1+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc') # unpacking arguments
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad') # arguments' index
'abracadabra'
```

### Accessing arguments by name:

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

### Accessing arguments' attributes:

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real}
... 'and the imaginary part {0.imag}.'.format(c)
'The complex number (3-5j) is formed from the real part 3 and the imaginary part -5'
>>> class Point:
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

### Accessing arguments' items:

```
>>> coord = (3, 5)
>>> 'X: {0[0]}; Y: {0[1]}'.format(coord)
'X: 3; Y: 5'
```

## Replacing %s and %r:

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
"repr() shows quotes: 'test1'; str() doesn't: test2"
```

## Aligning the text and specifying a width:

```
>>> '{:<30}'.format('left aligned')
'left aligned'
>>> '{:>30}'.format('right aligned')
'right aligned'
>>> '{:^30}'.format('centered')
'centered'
>>> '{:*^30}'.format('centered') # use '*' as a fill character
'*****centered*****'
```

## Replacing %+f, %-f, and % f and specifying a sign:

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14) # show it always with a sign
'+3.140000; -3.140000'
>>> '{: f}; {: f}'.format(3.14, -3.14) # show a space before the sign
' 3.140000; -3.140000'
>>> '{:-f}; {: -f}'.format(3.14, -3.14) # show only the sign
'3.140000; -3.140000'
```

## Replacing %x and %o and converting the value to different bases:

```
>>> # format also supports binary numbers
>>> "int: {0:d}; hex: {0:x}; oct: {0:o}; bin: {0:b}".format(42)
'int: 42; hex: 2a; oct: 52; bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
>>> "int: {0:d}; hex: {0:#x}; oct: {0:#o}; bin: {0:#b}".format(42)
'int: 42; hex: 0x2a; oct: 0o52; bin: 0b101010'
```

## Using the comma as a thousands separator:

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
```

## Expressing a percentage:

```
>>> points = 19
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 86.36%'
```

### Using type-specific formatting:

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

### Nesting arguments and more complex examples:

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, a=
...
'left<<<<<<<<<<'
'^^^^^center^^^^^'
'>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
'C0A80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print('{0:{width}{base}}'.format(num, base=b
...         print()
...
5      5      5      101
6      6      6      110
7      7      7      111
8      8      10     1000
9      9      11     1001
10     A      12     1010
```

## Template strings

Template strings provide simpler string substitutions as described in [PEP 292](https://peps.python.org/pep-0292/) [https://peps.python.org/pep-0292/]. A primary use case for template strings is for internationalization (i18n) since in that context, the simpler syntax and functionality makes it easier to translate than other built-in string formatting facilities in Python. As an example of a library built on template strings for i18n, see the [flufl.i18n](https://flufl.i18n.readthedocs.io/en/latest/) [https://flufl.i18n.readthedocs.io/en/latest/] package.

Template strings support `$`-based substitutions, using the following rules:

- `$$` is an escape; it is replaced with a single `$`.
- `$identifier` names a substitution placeholder matching a mapping key of `"identifier"`. By default, `"identifier"` is restricted to any case-insensitive ASCII alphanumeric string (including underscores) that starts with an underscore or ASCII letter. The first non-identifier character after the `$` character terminates this placeholder specification.
- `${identifier}` is equivalent to `$identifier`. It is required when valid identifier characters follow the placeholder but are not part of the placeholder, such as `"${noun}ification"`.

Any other appearance of `$` in the string will result in a **ValueError** being raised.

The **string** module provides a **Template** class that implements these rules. The methods of **Template** are:

`class string.Template(template)`

The constructor takes a single argument which is the template string.

`substitute(mapping={}, /, **kws)`

Performs the template substitution, returning a new string. *mapping* is any dictionary-like object with keys that match the placeholders in the template. Alternatively, you can provide keyword arguments, where the keywords are the placeholders. When both *mapping* and *kwds* are given and there are duplicates, the placeholders from *kwds* take precedence.

`safe_substitute(mapping={}, /, **kwds)`

Like `substitute()`, except that if placeholders are missing from *mapping* and *kwds*, instead of raising a `KeyError` exception, the original placeholder will appear in the resulting string intact. Also, unlike with `substitute()`, any other appearances of the `$` will simply return `$` instead of raising `ValueError`.

While other exceptions may still occur, this method is called “safe” because it always tries to return a usable string instead of raising an exception. In another sense, `safe_substitute()` may be anything other than safe, since it will silently ignore malformed templates containing dangling delimiters, unmatched braces, or placeholders that are not valid Python identifiers.

`is_valid()`

Returns false if the template has invalid placeholders that will cause `substitute()` to raise `ValueError`.

*New in version 3.11.*

`get_identifiers()`

Returns a list of the valid identifiers in the template, in the order they first appear, ignoring any invalid identifiers.

*New in version 3.11.*

`Template` instances also provide one public data attribute:

## template

This is the object passed to the constructor's *template* argument. In general, you shouldn't change it, but read-only access is not enforced.

Here is an example of how to use a Template:

```
>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 1
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

Advanced usage: you can derive subclasses of **Template** to customize the placeholder syntax, delimiter character, or the entire regular expression used to parse template strings. To do this, you can override these class attributes:

- *delimiter* – This is the literal string describing a placeholder introducing delimiter. The default value is `$`. Note that this should *not* be a regular expression, as the implementation will call `re.escape()` on this string as needed. Note further that you cannot change the delimiter after class creation (i.e. a different delimiter must be set in the subclass's class namespace).
- *idpattern* – This is the regular expression describing the pattern for non-braced placeholders. The default value is the regular expression `(?a: [_a-z] [_a-z0-9] *)`. If this is given and *braceidpattern* is `None` this pattern will also apply

to braced placeholders.

### Note

Since default *flags* is `re.IGNORECASE`, pattern `[a-z]` can match with some non-ASCII characters. That's why we use the local `a` flag here.

*Changed in version 3.7:* *braceidpattern* can be used to define separate patterns used inside and outside the braces.

- *braceidpattern* – This is like *idpattern* but describes the pattern for braced placeholders. Defaults to `None` which means to fall back to *idpattern* (i.e. the same pattern is used both inside and outside braces). If given, this allows you to define different patterns for braced and unbraced placeholders.

*New in version 3.7.*

- *flags* – The regular expression flags that will be applied when compiling the regular expression used for recognizing substitutions. The default value is `re.IGNORECASE`. Note that `re.VERBOSE` will always be added to the flags, so custom *idpatterns* must follow conventions for verbose regular expressions.

*New in version 3.2.*

Alternatively, you can provide the entire regular expression pattern by overriding the class attribute *pattern*. If you do this, the value must be a regular expression object with four named capturing groups. The capturing groups correspond to the rules given above, along with the invalid placeholder rule:

- *escaped* – This group matches the escape sequence, e.g. `$$`, in the default pattern.
- *named* – This group matches the unbraced placeholder name; it should not include the delimiter in capturing group.
- *braced* – This group matches the brace enclosed placeholder name; it should not include either the delimiter or braces in

the capturing group.

- *invalid* – This group matches any other delimiter pattern (usually a single delimiter), and it should appear last in the regular expression.

The methods on this class will raise `ValueError` if the pattern matches the template without one of these named groups matching.

## Helper functions

`string.capwords(s, sep=None)`

Split the argument into words using `str.split()`, capitalize each word using `str.capitalize()`, and join the capitalized words using `str.join()`. If the optional second argument *sep* is absent or `None`, runs of whitespace characters are replaced by a single space and leading and trailing whitespace are removed, otherwise *sep* is used to split and join the words.

# re — Regular expression operations

Source code: [Lib/re/](https://github.com/python/cpython/tree/3.11/Lib/re/) [https://github.com/python/cpython/tree/3.11/Lib/re/]

---

This module provides regular expression matching operations similar to those found in Perl.

Both patterns and strings to be searched can be Unicode strings (**str**) as well as 8-bit strings (**bytes**). However, Unicode strings and 8-bit strings cannot be mixed: that is, you cannot match a Unicode string with a byte pattern or vice-versa; similarly, when asking for a substitution, the replacement string must be of the same type as both the pattern and the search string.

Regular expressions use the backslash character ('\\') to indicate special forms or to allow special characters to be used without invoking their special meaning. This collides with Python's usage of the same character for the same purpose in string literals; for example, to match a literal backslash, one might have to write '\\\\' as the pattern string, because the regular expression must be '\\', and each backslash must be expressed as '\\ inside a regular Python string literal. Also, please note that any invalid escape sequences in Python's usage of the backslash in string literals now generate a **DeprecationWarning** and in the future this will become a **SyntaxError**. This behaviour will happen even if it is a valid escape sequence for a regular expression.

The solution is to use Python's raw string notation for regular expression patterns; backslashes are not handled in any special way in a string literal prefixed with 'r'. So `r"\n"` is a two-character string containing '\\' and '\n', while `"\n"` is a one-character string containing a newline. Usually patterns will be expressed in Python code using this raw string notation.

It is important to note that most regular expression operations are available as module-level functions and methods on [compiled regular expressions](#). The functions are shortcuts that don't require you to compile a regex object first, but miss some fine-tuning parameters.

### See also

The third-party [regex](https://pypi.org/project/regex/) [https://pypi.org/project/regex/] module, which has an API compatible with the standard library [re](#) module, but offers additional functionality and a more thorough Unicode support.

## Regular Expression Syntax

A regular expression (or RE) specifies a set of strings that matches it; the functions in this module let you check if a particular string matches a given regular expression (or if a given regular expression matches a particular string, which comes down to the same thing).

Regular expressions can be concatenated to form new regular expressions; if *A* and *B* are both regular expressions, then *AB* is also a regular expression. In general, if a string *p* matches *A* and another string *q* matches *B*, the string *pq* will match *AB*. This holds unless *A* or *B* contain low precedence operations; boundary conditions between *A* and *B*; or have numbered group references. Thus, complex expressions can easily be constructed from simpler primitive expressions like the ones described here. For details of the theory and implementation of regular expressions, consult the Friedl book [\[Frie09\]](#), or almost any textbook about compiler construction.

A brief explanation of the format of regular expressions follows. For further information and a gentler presentation, consult the [Regular Expression HOWTO](#).

Regular expressions can contain both special and ordinary characters. Most ordinary characters, like 'A', 'a', or '0', are the simplest regular expressions; they simply match themselves.

You can concatenate ordinary characters, so `last` matches the string `'last'`. (In the rest of this section, we'll write RE's in this special style, usually without quotes, and strings to be matched 'in single quotes'.)

Some characters, like `'|'` or `'('`, are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted.

Repetition operators or quantifiers (`*`, `+`, `?`, `{m,n}`, etc) cannot be directly nested. This avoids ambiguity with the non-greedy modifier suffix `?`, and with other modifiers in other implementations. To apply a second repetition to an inner repetition, parentheses may be used. For example, the expression `(?:a{6})*` matches any multiple of six `'a'` characters.

The special characters are:

**.** (Dot.) In the default mode, this matches any character except a newline. If the **DOTALL** flag has been specified, this matches any character including a newline.

**^** (Caret.) Matches the start of the string, and in **MULTILINE** mode also matches immediately after each newline.

**\$** Matches the end of the string or just before the newline at the end of the string, and in **MULTILINE** mode also matches before a newline. `foo` matches both `'foo'` and `'foobar'`, while the regular expression `foo$` matches only `'foo'`. More interestingly, searching for `foo.$` in `'foo1\nfoo2\n'` matches `'foo2'` normally, but `'foo1'` in **MULTILINE** mode; searching for a single `$` in `'foo\n'` will find two (empty) matches: one just before the newline, and one at the end of the string.

**\*** Causes the resulting RE to match 0 or more repetitions of the

preceding RE, as many repetitions as are possible. `ab*` will match 'a', 'ab', or 'a' followed by any number of 'b's.

+

Causes the resulting RE to match 1 or more repetitions of the preceding RE. `ab+` will match 'a' followed by any non-zero number of 'b's; it will not match just 'a'.

?

Causes the resulting RE to match 0 or 1 repetitions of the preceding RE. `ab?` will match either 'a' or 'ab'.

`*?`, `+`, `??`

The `'*'`, `'+'`, and `'?'` quantifiers are all *greedy*; they match as much text as possible. Sometimes this behaviour isn't desired; if the RE `<.*>` is matched against `'<a> b <c>'`, it will match the entire string, and not just `'<a>'`. Adding `?` after the quantifier makes it perform the match in *non-greedy* or *minimal* fashion; as few characters as possible will be matched. Using the RE `<.*?>` will match only `'<a>'`.

`*+`, `++`, `?+`

Like the `'*'`, `'+'`, and `'?'` quantifiers, those where `'+'` is appended also match as many times as possible. However, unlike the true greedy quantifiers, these do not allow backtracking when the expression following it fails to match. These are known as *possessive* quantifiers. For example, `a*a` will match `'aaaa'` because the `a*` will match all 4 'a's, but, when the final 'a' is encountered, the expression is backtracked so that in the end the `a*` ends up matching 3 'a's total, and the fourth 'a' is matched by the final 'a'. However, when `a*+a` is used to match `'aaaa'`, the `a*+` will match all 4 'a', but when the final 'a' fails to find any more characters to match, the expression cannot be backtracked and will thus fail to match. `x*+`, `x++` and `x?+` are equivalent to `(?>x*)`, `(?>x+)` and `(?>x?)` correspondingly.

### *New in version 3.11.*

`{m}`

Specifies that exactly  $m$  copies of the previous RE should be matched; fewer matches cause the entire RE not to match. For example, `a{6}` will match exactly six 'a' characters, but not five.

`{m, n}`

Causes the resulting RE to match from  $m$  to  $n$  repetitions of the preceding RE, attempting to match as many repetitions as possible. For example, `a{3, 5}` will match from 3 to 5 'a' characters. Omitting  $m$  specifies a lower bound of zero, and omitting  $n$  specifies an infinite upper bound. As an example, `a{4, }b` will match 'aaaab' or a thousand 'a' characters followed by a 'b', but not 'aaab'. The comma may not be omitted or the modifier would be confused with the previously described form.

`{m, n}?`

Causes the resulting RE to match from  $m$  to  $n$  repetitions of the preceding RE, attempting to match as *few* repetitions as possible. This is the non-greedy version of the previous quantifier. For example, on the 6-character string 'aaaaaa', `a{3, 5}` will match 5 'a' characters, while `a{3, 5}?` will only match 3 characters.

`{m, n}+`

Causes the resulting RE to match from  $m$  to  $n$  repetitions of the preceding RE, attempting to match as many repetitions as possible *without* establishing any backtracking points. This is the possessive version of the quantifier above. For example, on the 6-character string 'aaaaaa', `a{3, 5}+aa` attempt to match 5 'a' characters, then, requiring 2 more 'a's, will need more characters than available and thus fail, while `a{3, 5}aa` will match with `a{3, 5}` capturing 5, then 4 'a's by backtracking and then the final 2 'a's are matched by the final `aa` in the pattern. `x{m, n}+` is equivalent to `(?>x{m, n})`.

*New in version 3.11.*

\

Either escapes special characters (permitting you to match characters like `'*'`, `'?'`, and so forth), or signals a special sequence; special sequences are discussed below.

If you're not using a raw string to express the pattern, remember that Python also uses the backslash as an escape sequence in string literals; if the escape sequence isn't recognized by Python's parser, the backslash and subsequent character are included in the resulting string. However, if Python would recognize the resulting sequence, the backslash should be repeated twice. This is complicated and hard to understand, so it's highly recommended that you use raw strings for all but the simplest expressions.

[ ]

Used to indicate a set of characters. In a set:

- Characters can be listed individually, e.g. `[amk]` will match `'a'`, `'m'`, or `'k'`.
- Ranges of characters can be indicated by giving two characters and separating them by a `'-'`, for example `[a-z]` will match any lowercase ASCII letter, `[0-5]` `[0-9]` will match all the two-digits numbers from 00 to 59, and `[0-9A-Fa-f]` will match any hexadecimal digit. If `-` is escaped (e.g. `[a\ -z]`) or if it's placed as the first or last character (e.g. `[-a]` or `[a-]`), it will match a literal `'-'`.
- Special characters lose their special meaning inside sets. For example, `[ (+* ) ]` will match any of the literal characters `'('`, `'+'`, `'*'`, or `)'`.
- Character classes such as `\w` or `\S` (defined below) are also accepted inside a set, although the characters they match depends on whether **ASCII** or **LOCALE** mode is in force.

- Characters that are not within a range can be matched by *complementing* the set. If the first character of the set is `'^'`, all the characters that are *not* in the set will be matched. For example, `[^5]` will match any character except `'5'`, and `[^^]` will match any character except `'^'`. `^` has no special meaning if it's not the first character in the set.
- To match a literal `' ] '` inside a set, precede it with a backslash, or place it at the beginning of the set. For example, both `[ ( ) [ \ ] { } ]` and `[ ] ( ) [ { } ]` will match a right bracket, as well as left bracket, braces, and parentheses.
- Support of nested sets and set operations as in [Unicode Technical Standard #18](https://unicode.org/reports/tr18/) [https://unicode.org/reports/tr18/] might be added in the future. This would change the syntax, so to facilitate this change a **FutureWarning** will be raised in ambiguous cases for the time being. That includes sets starting with a literal `' ['` or containing literal character sequences `'--'`, `'&&'`, `'~~'`, and `' | '`. To avoid a warning escape them with a backslash.

*Changed in version 3.7:* **FutureWarning** is raised if a character set contains constructs that will change semantically in the future.

`A|B`, where *A* and *B* can be arbitrary REs, creates a regular expression that will match either *A* or *B*. An arbitrary number of REs can be separated by the `'|'` in this way. This can be used inside groups (see below) as well. As the target string is scanned, REs separated by `'|'` are tried from left to right. When one pattern completely matches, that branch is accepted. This means that once *A* matches, *B* will not be tested further, even if it would produce a longer overall match. In other words, the `'|'` operator is never greedy. To match a literal `'|'`, use `\|`, or enclose it inside a character class, as in `[|]`.

(...)

Matches whatever regular expression is inside the parentheses, and indicates the start and end of a group; the contents of a group can be retrieved after a match has been performed, and can be matched later in the string with the `\number` special sequence, described below. To match the literals `' ( ' or ' ) '`, use `\ ( or \ )`, or enclose them inside a character class: `[ ( ], [ ) ]`.

(?...)

This is an extension notation (a `' ? '` following a `' ( '` is not meaningful otherwise). The first character after the `' ? '` determines what the meaning and further syntax of the construct is. Extensions usually do not create a new group; `(?P<name>...)` is the only exception to this rule. Following are the currently supported extensions.

(?aiLmsux)

(One or more letters from the set `' a ', ' i ', ' L ', ' m ', ' s ', ' u ', ' x '`.) The group matches the empty string; the letters set the corresponding flags: **re.A** (ASCII-only matching), **re.I** (ignore case), **re.L** (locale dependent), **re.M** (multi-line), **re.S** (dot matches all), **re.U** (Unicode matching), and **re.X** (verbose), for the entire regular expression. (The flags are described in [Module Contents](#).) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the **re.compile()** function. Flags should be used first in the expression string.

*Changed in version 3.11:* This construction can only be used at the start of the expression.

(?:...)

A non-capturing version of regular parentheses. Matches whatever regular expression is inside the parentheses, but the substring matched by the group *cannot* be retrieved after performing a match or referenced later in the pattern.

(?aiLmsux-imsx:...)

(Zero or more letters from the set 'a', 'i', 'L', 'm', 's', 'u', 'x', optionally followed by '-' followed by one or more letters from the 'i', 'm', 's', 'x'.) The letters set or remove the corresponding flags: **re.A** (ASCII-only matching), **re.I** (ignore case), **re.L** (locale dependent), **re.M** (multi-line), **re.S** (dot matches all), **re.U** (Unicode matching), and **re.X** (verbose), for the part of the expression. (The flags are described in [Module Contents](#).)

The letters 'a', 'L' and 'u' are mutually exclusive when used as inline flags, so they can't be combined or follow '-'. Instead, when one of them appears in an inline group, it overrides the matching mode in the enclosing group. In Unicode patterns (?a:... ) switches to ASCII-only matching, and (?u:... ) switches to Unicode matching (default). In byte pattern (?L:... ) switches to locale depending matching, and (?a:... ) switches to ASCII-only matching (default). This override is only in effect for the narrow inline group, and the original matching mode is restored outside of the group.

*New in version 3.6.*

*Changed in version 3.7:* The letters 'a', 'L' and 'u' also can be used in a group.

(?>...)

Attempts to match ... as if it was a separate regular expression, and if successful, continues to match the rest of the pattern following it. If the subsequent pattern fails to match, the stack can only be unwound to a point *before* the (?>...) because once exited, the expression, known as an *atomic group*, has thrown away all stack points within itself. Thus, (?>.\*). would never match anything because first the .\* would match all characters possible, then, having nothing left to match, the final . would fail to match. Since there are no stack points saved in the Atomic Group, and there is no stack point before it, the entire expression would thus fail to match.

*New in version 3.11.*

`(?P<name>...)`

Similar to regular parentheses, but the substring matched by the group is accessible via the symbolic group name *name*. Group names must be valid Python identifiers, and each group name must be defined only once within a regular expression. A symbolic group is also a numbered group, just as if the group were not named.

Named groups can be referenced in three contexts. If the pattern is `(?P<quote>['"])*?(?P=quote)` (i.e. matching a string quoted with either single or double quotes):

**Way to reference to group “quote”**

---

in the same pattern (as shown)

- `\1`

---

when processing match object *m*

- `m.end('quote')` (etc.)

---

in a string passed to the *repl* argument of `re.sub()`

- `\g<1>`
  - `\1`
- 

*Deprecated since version 3.11:* Group *name* containing characters outside the ASCII range (`b'\x00'-b'\x7f'`) in **bytes** patterns.

`(?P=name)`

A backreference to a named group; it matches whatever text was matched by the earlier group named *name*.

`(?#...)`

A comment; the contents of the parentheses are simply ignored.

`(?=...)`

Matches if `...` matches next, but doesn't consume any of the string. This is called a *lookahead assertion*. For example, `Isaac (?=Asimov)` will match `'Isaac '` only if it's followed by `'Asimov'`.

(?!...)

Matches if ... doesn't match next. This is a *negative lookahead assertion*. For example, `Isaac (?!Asimov)` will match `'Isaac '` only if it's *not* followed by `'Asimov'`.

(?<=...)

Matches if the current position in the string is preceded by a match for ... that ends at the current position. This is called a *positive lookbehind assertion*. `(?<=abc)def` will find a match in `'abcdef'`, since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that `abc` or `a|b` are allowed, but `a*` and `a{3,4}` are not. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the `search()` function rather than the `match()` function:

```
>>> import re
>>> m = re.search('(?!<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

This example looks for a word following a hyphen:

```
>>> m = re.search(r'(?<=-)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

*Changed in version 3.5:* Added support for group references of fixed length.

(?<!...)

Matches if the current position in the string is not preceded by a match for .... This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

`(?(id/name)yes-pattern|no-pattern)`

Will try to match with `yes-pattern` if the group with given *id* or *name* exists, and with `no-pattern` if it doesn't. `no-pattern` is optional and can be omitted. For example, `(<)?(\w+@(\w+)(?:\.\w+)+)(?(1)>|$\)` is a poor email matching pattern, which will match with `'<user@host.com>'` as well as `'user@host.com'`, but not with `'<user@host.com'` nor `'user@host.com>'`.

*Deprecated since version 3.11:* Group *id* containing anything except ASCII digits. Group *name* containing characters outside the ASCII range (b'\x00'-b'\x7f') in [bytes](#) replacement strings.

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not an ASCII digit or an ASCII letter, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

`\number`

Matches the contents of the group of the same number. Groups are numbered starting from 1. For example, `(.+)\1` matches `'the the'` or `'55 55'`, but not `'thethe'` (note the space after the group). This special sequence can only be used to match one of the first 99 groups. If the first digit of *number* is 0, or *number* is 3 octal digits long, it will not be interpreted as a group match, but as the character with octal value *number*. Inside the `'['` and `']'` of a character class, all numeric escapes are treated as characters.

`\A`

Matches only at the start of the string.

`\b`

Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of word characters. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning/end of the string. This means that `r'\bfoo`

`\b` matches `'foo'`, `'foo.'`, `'(foo)'`, `'bar foo baz'` but not `'foobar'` or `'foo3'`.

By default Unicode alphanumerics are the ones used in Unicode patterns, but this can be changed by using the **ASCII** flag. Word boundaries are determined by the current locale if the **LOCALE** flag is used. Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

`\B`

Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'py\B'` matches `'python'`, `'py3'`, `'py2'`, but not `'py'`, `'py.'`, or `'py!'`. `\B` is just the opposite of `\b`, so word characters in Unicode patterns are Unicode alphanumerics or the underscore, although this can be changed by using the **ASCII** flag. Word boundaries are determined by the current locale if the **LOCALE** flag is used.

`\d`

For Unicode (str) patterns:

Matches any Unicode decimal digit (that is, any character in Unicode character category `[Nd]`). This includes `[0-9]`, and also many other digit characters. If the **ASCII** flag is used only `[0-9]` is matched.

For 8-bit (bytes) patterns:

Matches any decimal digit; this is equivalent to `[0-9]`.

`\D`

Matches any character which is not a decimal digit. This is the opposite of `\d`. If the **ASCII** flag is used this becomes the equivalent of `[^0-9]`.

`\s`

For Unicode (str) patterns:

Matches Unicode whitespace characters (which

includes [ \t\n\r\f\v], and also many other characters, for example the non-breaking spaces mandated by typography rules in many languages). If the **ASCII** flag is used, only [ \t\n\r\f\v] is matched.

For 8-bit (bytes) patterns:

Matches characters considered whitespace in the ASCII character set; this is equivalent to [ \t\n\r\f\v].

\S

Matches any character which is not a whitespace character. This is the opposite of \s. If the **ASCII** flag is used this becomes the equivalent of [^ \t\n\r\f\v].

\w

For Unicode (str) patterns:

Matches Unicode word characters; this includes alphanumeric characters (as defined by **str.isalnum()**) as well as the underscore (\_). If the **ASCII** flag is used, only [a-zA-Z0-9\_] is matched.

For 8-bit (bytes) patterns:

Matches characters considered alphanumeric in the ASCII character set; this is equivalent to [a-zA-Z0-9\_]. If the **LOCALE** flag is used, matches characters considered alphanumeric in the current locale and the underscore.

\W

Matches any character which is not a word character. This is the opposite of \w. If the **ASCII** flag is used this becomes the equivalent of [^a-zA-Z0-9\_]. If the **LOCALE** flag is used, matches characters which are neither alphanumeric in the current locale nor the underscore.

\Z

Matches only at the end of the string.

Most of the standard escapes supported by Python string literals are also accepted by the regular expression parser:

|                 |                 |                 |                 |
|-----------------|-----------------|-----------------|-----------------|
| <code>\a</code> | <code>\b</code> | <code>\f</code> | <code>\n</code> |
| <code>\N</code> | <code>\r</code> | <code>\t</code> | <code>\u</code> |
| <code>\U</code> | <code>\v</code> | <code>\x</code> | <code>\\</code> |

(Note that `\b` is used to represent word boundaries, and means “backspace” only inside character classes.)

`'\u'`, `'\U'`, and `'\N'` escape sequences are only recognized in Unicode patterns. In bytes patterns they are errors. Unknown escapes of ASCII letters are reserved for future use and treated as errors.

Octal escapes are included in a limited form. If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in length.

*Changed in version 3.3:* The `'\u'` and `'\U'` escape sequences have been added.

*Changed in version 3.6:* Unknown escapes consisting of `'\'` and an ASCII letter now are errors.

*Changed in version 3.8:* The `'\N{name}'` escape sequence has been added. As in string literals, it expands to the named Unicode character (e.g. `'\N{EM DASH}'`).

## Module Contents

The module defines several functions, constants, and an exception. Some of the functions are simplified versions of the full featured methods for compiled regular expressions. Most non-trivial applications always use the compiled form.

### Flags

*Changed in version 3.6:* Flag constants are now instances of

**RegexFlag**, which is a subclass of **enum.IntFlag**.

*class* re.RegexFlag

An **enum.IntFlag** class containing the regex options listed below.

*New in version 3.11:* - added to `__all__`

re.A

re.ASCII

Make `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` and `\S` perform ASCII-only matching instead of full Unicode matching. This is only meaningful for Unicode patterns, and is ignored for byte patterns. Corresponds to the inline flag `(?a)`.

Note that for backward compatibility, the **re.U** flag still exists (as well as its synonym **re.UNICODE** and its embedded counterpart `(?u)`), but these are redundant in Python 3 since matches are Unicode by default for strings (and Unicode matching isn't allowed for bytes).

re.DEBUG

Display debug information about compiled expression. No corresponding inline flag.

re.I

re.IGNORECASE

Perform case-insensitive matching; expressions like `[A-Z]` will also match lowercase letters. Full Unicode matching (such as `Ü` matching `ü`) also works unless the **re.ASCII** flag is used to disable non-ASCII matches. The current locale does not change the effect of this flag unless the **re.LOCALE** flag is also used. Corresponds to the inline flag `(?i)`.

Note that when the Unicode patterns `[a-z]` or `[A-Z]` are used in combination with the **IGNORECASE** flag, they will match the 52 ASCII letters and 4 additional non-ASCII letters: 'İ' (U+0130, Latin capital letter I with dot above), 'ı' (U+0131, Latin small letter dotless i), 'ŀ' (U+017F, Latin small

letter long s) and ‘K’ (U + 212A, Kelvin sign). If the `ASCII` flag is used, only letters ‘a’ to ‘z’ and ‘A’ to ‘Z’ are matched.

re.L

re.LOCALE

Make `\w`, `\W`, `\b`, `\B` and case-insensitive matching dependent on the current locale. This flag can be used only with bytes patterns. The use of this flag is discouraged as the locale mechanism is very unreliable, it only handles one “culture” at a time, and it only works with 8-bit locales. Unicode matching is already enabled by default in Python 3 for Unicode (str) patterns, and it is able to handle different locales/languages. Corresponds to the inline flag `(?L)`.

*Changed in version 3.6:* `re.LOCALE` can be used only with bytes patterns and is not compatible with `re.ASCII`.

*Changed in version 3.7:* Compiled regular expression objects with the `re.LOCALE` flag no longer depend on the locale at compile time. Only the locale at matching time affects the result of matching.

re.M

re.MULTILINE

When specified, the pattern character `^` matches at the beginning of the string and at the beginning of each line (immediately following each newline); and the pattern character `$` matches at the end of the string and at the end of each line (immediately preceding each newline). By default, `^` matches only at the beginning of the string, and `$` only at the end of the string and immediately before the newline (if any) at the end of the string. Corresponds to the inline flag `(?m)`.

re.NOFLAG

Indicates no flag being applied, the value is `0`. This flag may be used as a default value for a function keyword argument or as a base value that will be conditionally ORed with other flags. Example of use as a default value:

```
def myfunc(text, flag=re.NOFLAG):  
    return re.match(text, flag)
```

*New in version 3.11.*

re.S

re.DOTALL

Make the `'.'` special character match any character at all, including a newline; without this flag, `'.'` will match anything *except* a newline. Corresponds to the inline flag `(?s)`.

re.X

re.VERBOSE

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored, except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. For example, `(?:` : and `* ?` are not allowed. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

This means that the two following regular expression objects that match a decimal number are functionally equal:

```
a = re.compile(r"""\d +    # the integral part  
                \.        # the decimal point  
                \d *      # some fractional digits""")  
b = re.compile(r"\d+\.\d*")
```

Corresponds to the inline flag `(?x)`.

## Functions

`re.compile(pattern, flags=0)`

Compile a regular expression pattern into a [regular expression](#)

**object**, which can be used for matching using its `match()`, `search()` and other methods, described below.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the following variables, combined using bitwise OR (the `|` operator).

The sequence

```
prog = re.compile(pattern)
result = prog.match(string)
```

is equivalent to

```
result = re.match(pattern, string)
```

but using `re.compile()` and saving the resulting regular expression object for reuse is more efficient when the expression will be used several times in a single program.

### Note

The compiled versions of the most recent patterns passed to `re.compile()` and the module-level matching functions are cached, so programs that use only a few regular expressions at a time needn't worry about compiling regular expressions.

`re.search(pattern, string, flags=0)`

Scan through *string* looking for the first location where the regular expression *pattern* produces a match, and return a corresponding **match object**. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

`re.match(pattern, string, flags=0)`

If zero or more characters at the beginning of *string* match the regular expression *pattern*, return a corresponding **match object**. Return `None` if the string does not match the pattern;

note that this is different from a zero-length match.

Note that even in **MULTILINE** mode, `re.match()` will only match at the beginning of the string and not at the beginning of each line.

If you want to locate a match anywhere in *string*, use `search()` instead (see also `search() vs. match()`).

`re.fullmatch(pattern, string, flags=0)`

If the whole *string* matches the regular expression *pattern*, return a corresponding **match object**. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

*New in version 3.4.*

`re.split(pattern, string, maxsplit=0, flags=0)`

Split *string* by the occurrences of *pattern*. If capturing parentheses are used in *pattern*, then the text of all groups in the pattern are also returned as part of the resulting list. If *maxsplit* is nonzero, at most *maxsplit* splits occur, and the remainder of the string is returned as the final element of the list.

```
>>> re.split(r'\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split(r'(\W+)', 'Words, words, words.')
['Words', ', ', ', ', 'words', ', ', ', ', 'words', '.', '']
>>> re.split(r'\W+', 'Words, words, words.', 1)
['Words', 'words, words.']
>>> re.split('[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

If there are capturing groups in the separator and it matches at the start of the string, the result will start with an empty string. The same holds for the end of the string:

```
>>> re.split(r'(\W+)', '...words, words...')
```

```
['', '...', 'words', ',', ' ', 'words', '...', '']
```

That way, separator components are always found at the same relative indices within the result list.

Empty matches for the pattern split the string only when not adjacent to a previous empty match.

```
>>> re.split(r'\b', 'Words, words, words.')
['', 'Words', ',', ' ', 'words', ',', ' ', 'words', '.']
>>> re.split(r'\W*', '...words...')
['', '', 'w', 'o', 'r', 'd', 's', '', '']
>>> re.split(r'(\W*)', '...words...')
['', '...', '', '', 'w', '', 'o', '', 'r', '', 'd',
```

*Changed in version 3.1:* Added the optional `flags` argument.

*Changed in version 3.7:* Added support of splitting on a pattern that could match an empty string.

`re.findall(pattern, string, flags=0)`

Return all non-overlapping matches of *pattern* in *string*, as a list of strings or tuples. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

The result depends on the number of capturing groups in the pattern. If there are no groups, return a list of strings matching the whole pattern. If there is exactly one group, return a list of strings matching that group. If multiple groups are present, return a list of tuples of strings matching the groups. Non-capturing groups do not affect the form of the result.

```
>>> re.findall(r'\bf[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
>>> re.findall(r'(\w+)=(\d+)', 'set width=20 and height=10')
[('width', '20'), ('height', '10')]
```

*Changed in version 3.7:* Non-empty matches can now start just

after a previous empty match.

`re.finditer(pattern, string, flags=0)`

Return an [iterator](#) yielding [match objects](#) over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

*Changed in version 3.7:* Non-empty matches can now start just after a previous empty match.

`re.sub(pattern, repl, string, count=0, flags=0)`

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes of ASCII letters are reserved for future use and treated as errors. Other unknown escapes such as `\&` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example:

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*(\s*
...         r'static PyObject*\numpy_l(void)\n{',
...         'def myfunc():')
'static PyObject*\numpy_myfunc(void)\n{'
```

If *repl* is a function, it is called for every non-overlapping occurrence of *pattern*. The function takes a single [match object](#) argument, and returns the replacement string. For example:

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
>>> re.sub('-{1,2}', dashrepl, 'pro---gram-files')
'pro--gram files'
```

```
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam  
'Baked Beans & Spam')
```

The pattern may be a string or a [pattern object](#).

The optional argument *count* is the maximum number of pattern occurrences to be replaced; *count* must be a non-negative integer. If omitted or zero, all occurrences will be replaced. Empty matches for the pattern are replaced only when not adjacent to a previous empty match, so `sub('x*', '-', 'abxd')` returns `'-a-b--d-'`.

In string-type *repl* arguments, in addition to the character escapes and backreferences described above, `\g<name>` will use the substring matched by the group named *name*, as defined by the `(?P<name>...)` syntax. `\g<number>` uses the corresponding group number; `\g<2>` is therefore equivalent to `\2`, but isn't ambiguous in a replacement such as `\g<2>0`. `\20` would be interpreted as a reference to group 20, not a reference to group 2 followed by the literal character `'0'`. The backreference `\g<0>` substitutes in the entire substring matched by the RE.

*Changed in version 3.1:* Added the optional flags argument.

*Changed in version 3.5:* Unmatched groups are replaced with an empty string.

*Changed in version 3.6:* Unknown escapes in *pattern* consisting of `'\'` and an ASCII letter now are errors.

*Changed in version 3.7:* Unknown escapes in *repl* consisting of `'\'` and an ASCII letter now are errors.

*Changed in version 3.7:* Empty matches for the pattern are replaced when adjacent to a previous non-empty match.

*Deprecated since version 3.11:* Group *id* containing anything except ASCII digits. Group *name* containing characters outside the ASCII range (`b'\x00'-b'\x7f'`) in [bytes](#) replacement strings.

`re.subn(pattern, repl, string, count=0, flags=0)`

Perform the same operation as `sub()`, but return a tuple (new\_string, number\_of\_subs\_made).

*Changed in version 3.1:* Added the optional flags argument.

*Changed in version 3.5:* Unmatched groups are replaced with an empty string.

`re.escape(pattern)`

Escape special characters in *pattern*. This is useful if you want to match an arbitrary literal string that may have regular expression metacharacters in it. For example:

```
>>> print(re.escape('https://www.python.org'))
https://www\.python\.org
```

```
>>> legal_chars = string.ascii_lowercase + string.digits
>>> print('[%s]+' % re.escape(legal_chars))
[abcdefghijklmnopqrstuvwxyz0123456789!\#$%&'*\+\^_`{|}~]
```

```
>>> operators = ['+', '-', '*', '/', '**']
>>> print('|'.join(map(re.escape, sorted(operators,
/|\\-|\\+|\\*|\\*|\\*)))
```

This function must not be used for the replacement string in `sub()` and `subn()`, only backslashes should be escaped. For example:

```
>>> digits_re = r'\d+'
>>> sample = '/usr/sbin/sendmail - 0 errors, 12 warnings'
>>> print(re.sub(digits_re, digits_re.replace('\\d', '\\d+'),
/usr/sbin/sendmail - \d+ errors, \d+ warnings
```

*Changed in version 3.3:* The `'_'` character is no longer escaped.

*Changed in version 3.7:* Only characters that can have special meaning in a regular expression are escaped. As a result, `'!', '"', '%', '"', ',', '/', ':', ';', '<', '=',`

'>', '@', and "`" are no longer escaped.

`re.purge()`

Clear the regular expression cache.

## Exceptions

*exception* `re.error(msg, pattern=None, pos=None)`

Exception raised when a string passed to one of the functions here is not a valid regular expression (for example, it might contain unmatched parentheses) or when some other error occurs during compilation or matching. It is never an error if a string contains no match for a pattern. The error instance has the following additional attributes:

`msg`

The unformatted error message.

`pattern`

The regular expression pattern.

`pos`

The index in *pattern* where compilation failed (may be `None`).

`lineno`

The line corresponding to *pos* (may be `None`).

`colno`

The column corresponding to *pos* (may be `None`).

*Changed in version 3.5:* Added additional attributes.

## Regular Expression Objects

Compiled regular expression objects support the following methods

and attributes:

`Pattern.search(string[, pos[, endpos]])`

Scan through *string* looking for the first location where this regular expression produces a match, and return a corresponding [match object](#). Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional second parameter *pos* gives an index in the string where the search is to start; it defaults to `0`. This is not completely equivalent to slicing the string; the `'^'` pattern character matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter *endpos* limits how far the string will be searched; it will be as if the string is *endpos* characters long, so only the characters from *pos* to *endpos* - 1 will be searched for a match. If *endpos* is less than *pos*, no match will be found; otherwise, if *rx* is a compiled regular expression object, `rx.search(string, 0, 50)` is equivalent to `rx.search(string[:50], 0)`.

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")          # Match at index 0
<re.Match object; span=(0, 1), match='d'>
>>> pattern.search("dog", 1)      # No match; search do
```

`Pattern.match(string[, pos[, endpos]])`

If zero or more characters at the *beginning* of *string* match this regular expression, return a corresponding [match object](#). Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the [search\(\)](#) method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")          # No match as "o" is
```

```
>>> pattern.match("dog", 1)    # Match as "o" is the
<re.Match object; span=(1, 2), match='o'>
```

If you want to locate a match anywhere in *string*, use `search()` instead (see also `search() vs. match()`).

`Pattern.fullmatch(string[, pos[, endpos]])`

If the whole *string* matches this regular expression, return a corresponding `match object`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the `search()` method.

```
>>> pattern = re.compile("o[gh]")
>>> pattern.fullmatch("dog")      # No match as "o"
>>> pattern.fullmatch("ogre")     # No match as not
>>> pattern.fullmatch("doggie", 1, 3) # Matches w
<re.Match object; span=(1, 3), match='og'>
```

*New in version 3.4.*

`Pattern.split(string, maxsplit=0)`

Identical to the `split()` function, using the compiled pattern.

`Pattern.findall(string[, pos[, endpos]])`

Similar to the `findall()` function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for `search()`.

`Pattern.finditer(string[, pos[, endpos]])`

Similar to the `finditer()` function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for `search()`.

`Pattern.sub(repl, string, count=0)`

Identical to the `sub()` function, using the compiled pattern.

`Pattern.subn(repl, string, count=0)`

Identical to the `subn()` function, using the compiled pattern.

`Pattern.flags`

The regex matching flags. This is a combination of the flags given to `compile()`, any `(? . . .)` inline flags in the pattern, and implicit flags such as `UNICODE` if the pattern is a Unicode string.

`Pattern.groups`

The number of capturing groups in the pattern.

`Pattern.groupindex`

A dictionary mapping any symbolic group names defined by `(?P<id>)` to group numbers. The dictionary is empty if no symbolic groups were used in the pattern.

`Pattern.pattern`

The pattern string from which the pattern object was compiled.

*Changed in version 3.7:* Added support of `copy.copy()` and `copy.deepcopy()`. Compiled regular expression objects are considered atomic.

## Match Objects

Match objects always have a boolean value of `True`. Since `match()` and `search()` return `None` when there is no match, you can test whether there was a match with a simple `if` statement:

```
match = re.search(pattern, string)
```

```
if match:
    process(match)
```

Match objects support the following methods and attributes:

### Match.expand(*template*)

Return the string obtained by doing backslash substitution on the template string *template*, as done by the `sub()` method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group.

*Changed in version 3.5:* Unmatched groups are replaced with an empty string.

### Match.group([*group1*, ...])

Returns one or more subgroups of the match. If there is a single argument, the result is a single string; if there are multiple arguments, the result is a tuple with one item per argument. Without arguments, *group1* defaults to zero (the whole match is returned). If a *groupN* argument is zero, the corresponding return value is the entire matching string; if it is in the inclusive range [1..99], it is the string matching the corresponding parenthesized group. If a group number is negative or larger than the number of groups defined in the pattern, an `IndexError` exception is raised. If a group is contained in a part of the pattern that did not match, the corresponding result is `None`. If a group is contained in a part of the pattern that matched multiple times, the last match is returned.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)           # The entire match
'Isaac Newton'
>>> m.group(1)           # The first parenthesized subgroup
'Isaac'
>>> m.group(2)           # The second parenthesized subgroup
'Newton'
```

```
>>> m.group(1, 2)      # Multiple arguments give us a
('Isaac', 'Newton')
```

If the regular expression uses the `(?P<name>...)` syntax, the *groupN* arguments may also be strings identifying groups by their group name. If a string argument is not used as a group name in the pattern, an **IndexError** exception is raised.

A moderately complicated example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)"
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Named groups can also be referred to by their index:

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

If a group matches multiple times, only the last match is accessible:

```
>>> m = re.match(r"(...) +", "a1b2c3")  # Matches 3 times
>>> m.group(1)                          # Returns only the last
'c3'
```

### Match.\_getitem\_(g)

This is identical to `m.group(g)`. This allows easier access to an individual group from a match:

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m[0]          # The entire match
'Isaac Newton'
>>> m[1]          # The first parenthesized subgroup.
'Isaac'
```

```
>>> m[2]          # The second parenthesized subgroup.  
'Newton'
```

Named groups are supported as well:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)"  
>>> m['first_name']  
'Isaac'  
>>> m['last_name']  
'Newton'
```

*New in version 3.6.*

`Match.groups(default=None)`

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match; it defaults to `None`.

For example:

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")  
>>> m.groups()  
('24', '1632')
```

If we make the decimal place and everything after it optional, not all groups might participate in the match. These groups will default to `None` unless the *default* argument is given:

```
>>> m = re.match(r"(\d+)\.?(\d+)?", "24")  
>>> m.groups()          # Second group defaults to None  
('24', None)  
>>> m.groups('0')      # Now, the second group default  
('24', '0')
```

`Match.groupdict(default=None)`

Return a dictionary containing all the *named* subgroups of the match, keyed by the subgroup name. The *default* argument is used for groups that did not participate in the match; it

defaults to `None`. For example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)"
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

`Match.start([group])`

`Match.end([group])`

Return the indices of the start and end of the substring matched by *group*; *group* defaults to zero (meaning the whole matched substring). Return `-1` if *group* exists but did not contribute to the match. For a match object *m*, and a group *g* that did contribute to the match, the substring matched by group *g* (equivalent to `m.group(g)`) is

```
m.string[m.start(g):m.end(g)]
```

Note that `m.start(group)` will equal `m.end(group)` if *group* matched a null string. For example, after `m = re.search('b(c?)', 'cba')`, `m.start(0)` is 1, `m.end(0)` is 2, `m.start(1)` and `m.end(1)` are both 2, and `m.start(2)` raises an [IndexError](#) exception.

An example that will remove *remove\_this* from email addresses:

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

`Match.span([group])`

For a match *m*, return the 2-tuple `(m.start(group), m.end(group))`. Note that if *group* did not contribute to the match, this is `(-1, -1)`. *group* defaults to zero, the entire match.

`Match.pos`

The value of `pos` which was passed to the `search()` or `match()` method of a [regex object](#). This is the index into the string at which the RE engine started looking for a match.

### Match.endpos

The value of `endpos` which was passed to the `search()` or `match()` method of a [regex object](#). This is the index into the string beyond which the RE engine will not go.

### Match.lastindex

The integer index of the last matched capturing group, or `None` if no group was matched at all. For example, the expressions `(a)b`, `((a)(b))`, and `((ab))` will have `lastindex == 1` if applied to the string `'ab'`, while the expression `(a)(b)` will have `lastindex == 2`, if applied to the same string.

### Match.lastgroup

The name of the last matched capturing group, or `None` if the group didn't have a name, or if no group was matched at all.

### Match.re

The [regular expression object](#) whose `match()` or `search()` method produced this match instance.

### Match.string

The string passed to `match()` or `search()`.

*Changed in version 3.7:* Added support of `copy.copy()` and `copy.deepcopy()`. Match objects are considered atomic.

## Regular Expression Examples

### Checking for a Pair

In this example, we'll use the following helper function to display

match objects a little more gracefully:

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), ma
```

Suppose you are writing a poker program where a player's hand is represented as a 5-character string with each character representing a card, “a” for ace, “k” for king, “q” for queen, “j” for jack, “t” for 10, and “2” through “9” representing the card with that value.

To see if a given string is a valid hand, one could do the following:

```
>>> valid = re.compile(r"^[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q")) # Valid.
"<Match: 'akt5q', groups=()>"
>>> displaymatch(valid.match("akt5e")) # Invalid.
>>> displaymatch(valid.match("akt")) # Invalid.
>>> displaymatch(valid.match("727ak")) # Valid.
"<Match: '727ak', groups=()>"
```

That last hand, "727ak", contained a pair, or two of the same valued cards. To match this with a regular expression, one could use backreferences as such:

```
>>> pair = re.compile(r".*(.)*\1")
>>> displaymatch(pair.match("717ak")) # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak")) # No pairs.
>>> displaymatch(pair.match("354aa")) # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the **group()** method of the match object in the following manner:

```
>>> pair = re.compile(r".*(.)*\1")
>>> pair.match("717ak").group(1)
'7'
```

```
# Error because re.match() returns None, which doesn't h
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    re.match(r".*(.)*\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

## Simulating scanf()

Python does not currently have an equivalent to **scanf()**. Regular expressions are generally more powerful, though also more verbose, than **scanf()** format strings. The table below offers some more-or-less equivalent mappings between **scanf()** format tokens and regular expressions.

| Regular Expression                                                 |
|--------------------------------------------------------------------|
| <code>%c</code>                                                    |
| <code>[%5]</code>                                                  |
| <code>[%d+]? \d+</code>                                            |
| <code>[%e,] %E, (\d+   (%d\w*))?   \. \d+ ([eE] [-+]? \d+)?</code> |
| <code>[%i+]? (0[xX] [\dA-Fa-f]+   0[0-7]*   \d+)</code>            |
| <code>[%o+]? [0-7]+</code>                                         |
| <code>%s+</code>                                                   |
| <code>%d+</code>                                                   |
| <code>[%x,] %X(0[xX])? [\dA-Fa-f]+</code>                          |

To extract the filename and numbers from a string like

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

you would use a **scanf()** format like

```
%s - %d errors, %d warnings
```

The equivalent regular expression would be

```
(\S+) - (\d+) errors, (\d+) warnings
```

## search() vs. match()

Python offers different primitive operations based on regular expressions:

- `re.match()` checks for a match only at the beginning of the string
- `re.search()` checks for a match anywhere in the string (this is what Perl does by default)
- `re.fullmatch()` checks for entire string to be a match

For example:

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("c", "abcdef")     # Match
<re.Match object; span=(2, 3), match='c'>
>>> re.fullmatch("p.*n", "python") # Match
<re.Match object; span=(0, 6), match='python'>
>>> re.fullmatch("r.*n", "python") # No match
```

Regular expressions beginning with `'^'` can be used with `search()` to restrict the match at the beginning of the string:

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("^c", "abcdef")    # No match
>>> re.search("^a", "abcdef")    # Match
<re.Match object; span=(0, 1), match='a'>
```

Note however that in **MULTILINE** mode `match()` only matches at the beginning of the string, whereas using `search()` with a regular expression beginning with `'^'` will match at the beginning of each line.

```
>>> re.match("X", "A\nB\nX", re.MULTILINE) # No match
>>> re.search("^X", "A\nB\nX", re.MULTILINE) # Match
<re.Match object; span=(4, 5), match='X'>
```

## Making a Phonebook

`split()` splits a string into a list delimited by the passed pattern.

The method is invaluable for converting textual data into data structures that can be easily read and modified by Python as demonstrated in the following example that creates a phonebook.

First, here is the input. Normally it may come from a file, here we are using triple-quoted string syntax

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

The entries are separated by one or more newlines. Now we convert the string into a list with each nonempty line having its own entry:

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
 'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
 'Frank Burger: 925.541.7625 662 South Dogwood Way',
 'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finally, split each entry into a list with first name, last name, telephone number, and address. We use the `maxsplit` parameter of `split()` because the address has spaces, our splitting pattern, in it:

```
>>> [re.split("?: ", entry, 3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

The `?:` pattern matches the colon after the last name, so that it does not occur in the result list. With a `maxsplit` of 4, we could separate the house number from the street name:

```
>>> [re.split("?:? ", entry, 4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street']
['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley A']
['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood']
['Heather', 'Albrecht', '548.326.4584', '919', 'Park Plaza']
```

## Text Munging

**sub()** replaces every occurrence of a pattern with a string or the result of a function. This example demonstrates using **sub()** with a function to “munge” text, or randomize the order of all the characters in each word of a sentence except for the first and last characters:

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
>>> text = "Professor Abdolmalek, please report your absence"
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlobdk, pslaee reorpt your abnseces plmrp'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reorpt yuor asnebces potlm'
```

## Finding all Adverbs

**findall()** matches *all* occurrences of a pattern, not just the first one as **search()** does. For example, if a writer wanted to find all of the adverbs in some text, they might use **findall()** in the following manner:

```
>>> text = "He was carefully disguised but captured quickly"
>>> re.findall(r"\w+ly\b", text)
['carefully', 'quickly']
```

## Finding all Adverbs and their Positions

If one wants more information about all matches of a pattern than the matched text, **finditer()** is useful as it provides **match**

**objects** instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use **finditer()** in the following manner:

```
>>> text = "He was carefully disguised but captured quickly  
>>> for m in re.finditer(r"\w+ly\b", text):  
...     print('%02d-%02d: %s' % (m.start(), m.end(), m.group()))  
07-16: carefully  
40-47: quickly
```

## Raw String Notation

Raw string notation (`r"text"`) keeps regular expressions sane. Without it, every backslash (`'\'`) in a regular expression would have to be prefixed with another one to escape it. For example, the two following lines of code are functionally identical:

```
>>> re.match(r"\W(.)\1\W", " ff ")  
<re.Match object; span=(0, 4), match=' ff '>  
>>> re.match("\\W(.)\\1\\W", " ff ")  
<re.Match object; span=(0, 4), match=' ff '>
```

When one wants to match a literal backslash, it must be escaped in the regular expression. With raw string notation, this means `r"\\"`. Without raw string notation, one must use `"\\\\"`, making the following lines of code functionally identical:

```
>>> re.match(r"\\", r"\\")  
<re.Match object; span=(0, 1), match='\\ '>  
>>> re.match("\\\\", r"\\")  
<re.Match object; span=(0, 1), match='\\ '>
```

## Writing a Tokenizer

A **tokenizer** or **scanner** [[https://en.wikipedia.org/wiki/Lexical\\_analysis](https://en.wikipedia.org/wiki/Lexical_analysis)] analyzes a string to categorize groups of characters. This is a useful first step in writing a compiler or interpreter.

The text categories are specified with regular expressions. The technique is to combine those into a single master regular

expression and to loop over successive matches:

```
from typing import NamedTuple
import re

class Token(NamedTuple):
    type: str
    value: str
    line: int
    column: int

def tokenize(code):
    keywords = {'IF', 'THEN', 'ENDIF', 'FOR', 'NEXT', 'GOTO', 'END', 'WHILE', 'DO', 'UNTIL', 'REPEAT', 'FORWARD', 'BACKWARD', 'STOP', 'CONTINUE', 'GOTO', 'CALL', 'RETURN', 'EXIT', 'END', 'ENDPROC', 'ENDSUB', 'ENDFUNCTION', 'ENDMODULE', 'ENDCLASS', 'ENDINTERFACE', 'ENDPACKAGE', 'ENDPROJECT', 'ENDSYSTEM', 'ENDUSER', 'ENDVENDOR', 'ENDCUSTOMER', 'ENDPARTNER', 'ENDSUPPLIER', 'ENDDISTRIBUTOR', 'ENDRETAILER', 'ENDWHOLESALE', 'ENDMANUFACTURER', 'ENDDISTRIBUTOR', 'ENDRETAILER', 'ENDWHOLESALE', 'ENDMANUFACTURER'}
    token_specification = [
        ('NUMBER', r'\d+(\.\d*)?'), # Integer or decimal
        ('ASSIGN', r':='), # Assignment operator
        ('END', r';'), # Statement terminator
        ('ID', r'[A-Za-z]+'), # Identifiers
        ('OP', r'[+-*/*]'), # Arithmetic operators
        ('NEWLINE', r'\n'), # Line endings
        ('SKIP', r'[ \t]+'), # Skip over spaces and tabs
        ('MISMATCH', r'.'), # Any other character
    ]
    tok_regex = '|'.join('(?P<%s>%s)' % pair for pair in token_specification)
    line_num = 1
    line_start = 0
    for mo in re.finditer(tok_regex, code):
        kind = mo.lastgroup
        value = mo.group()
        column = mo.start() - line_start
        if kind == 'NUMBER':
            value = float(value) if '.' in value else int(value)
        elif kind == 'ID' and value in keywords:
            kind = value
        elif kind == 'NEWLINE':
            line_start = mo.end()
            line_num += 1
            continue
        elif kind == 'SKIP':
            continue
        else:
            raise ValueError('Invalid token %s' % kind)
```

```

        continue
    elif kind == 'MISMATCH':
        raise RuntimeError(f'{value!r} unexpected on
    yield Token(kind, value, line_num, column)

statements = '''
    IF quantity THEN
        total := total + price * quantity;
        tax := price * 0.05;
    ENDIF;
'''

for token in tokenize(statements):
    print(token)

```

The tokenizer produces the following output:

```

Token(type='IF', value='IF', line=2, column=4)
Token(type='ID', value='quantity', line=2, column=7)
Token(type='THEN', value='THEN', line=2, column=16)
Token(type='ID', value='total', line=3, column=8)
Token(type='ASSIGN', value=':=', line=3, column=14)
Token(type='ID', value='total', line=3, column=17)
Token(type='OP', value='+', line=3, column=23)
Token(type='ID', value='price', line=3, column=25)
Token(type='OP', value='*', line=3, column=31)
Token(type='ID', value='quantity', line=3, column=33)
Token(type='END', value=';', line=3, column=41)
Token(type='ID', value='tax', line=4, column=8)
Token(type='ASSIGN', value=':=', line=4, column=12)
Token(type='ID', value='price', line=4, column=15)
Token(type='OP', value='*', line=4, column=21)
Token(type='NUMBER', value=0.05, line=4, column=23)
Token(type='END', value=';', line=4, column=27)
Token(type='ENDIF', value='ENDIF', line=5, column=4)
Token(type='END', value=';', line=5, column=9)

```

O'Reilly Media, 2009. The third edition of the book no longer covers Python at all, but the first edition covered writing good regular expression patterns in great detail.

# difflib — Helpers for computing deltas

**Source code:** [Lib/difflib.py](https://github.com/python/cpython/tree/3.11/Lib/difflib.py) [<https://github.com/python/cpython/tree/3.11/Lib/difflib.py>]

---

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce information about file differences in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the [filecmp](#) module.

*class* `difflib.SequenceMatcher`

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are [hashable](#). The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name “gestalt pattern matching.” The idea is to find the longest contiguous matching subsequence that contains no “junk” elements; these “junk” elements are ones that are uninteresting in some sense, such as blank lines or whitespace. (Handling junk is an extension to the Ratcliff and Obershelp algorithm.) The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that “look right” to people.

**Timing:** The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. [SequenceMatcher](#) is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

**Automatic junk heuristic:** `SequenceMatcher` supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as “popular” and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the `autojunk` argument to `False` when creating the `SequenceMatcher`.

*New in version 3.2:* The *autojunk* parameter.

`class difflib.Differ`

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses `SequenceMatcher` both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a `Differ` delta begins with a two-letter code:

**~~Meaning~~**

---

line unique to sequence 1

---

line unique to sequence 2

---

line common to both sequences

---

line not present in either input sequence

---

Lines beginning with ‘?’ attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain tab characters.

`class difflib.HtmlDiff`

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is:

```
__init__(tabsize = 8, wrapcolumn = None, linejunk = None,  
charjunk = IS_CHARACTER_JUNK)
```

Initializes instance of `HtmlDiff`.

*tabsize* is an optional keyword argument to specify tab stop spacing and defaults to 8.

*wrapcolumn* is an optional keyword to specify column number where lines are broken and wrapped, defaults to `None` where lines are not wrapped.

*linejunk* and *charjunk* are optional keyword arguments passed into `ndiff()` (used by `HtmlDiff` to generate the side by side HTML differences). See `ndiff()` documentation for argument default values and descriptions.

The following methods are public:

```
make_file(fromlines, tolines, fromdesc = "", todesc = "",  
context = False, numlines = 5, *, charset = 'utf-8')
```

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

*fromdesc* and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

*context* and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to 5. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight

when using the “next” hyperlinks (setting to zero would cause the “next” hyperlinks to place the next difference highlight at the top of the browser without any leading context).

### Note

*fromdesc* and *todesc* are interpreted as unescaped HTML and should be properly escaped while receiving input from untrusted sources.

*Changed in version 3.5:* *charset* keyword-only argument was added. The default charset of HTML document changed from 'ISO-8859-1' to 'utf-8'.

```
make_table(fromlines, tolines, fromdesc="", todesc="",  
context=False, numlines=5)
```

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the `make_file()` method.

`Tools/scripts/diff.py` is a command-line front-end to this class and contains a good example of its use.

```
difflib.context_diff(a, b, fromfile="", tofile="", fromfiledate="",  
tofiledate="", n=3, lineterm='\n')
```

Compare *a* and *b* (lists of strings); return a delta (a [generator](#) generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are

created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(context_diff(s1, s2, fromfile='before.py',
tofile='after.py'))
*** 1,4 ****
! bacon
! eggs
! ham
! guido
--- 1,4 ----
! python
! eggy
! hamster
! guido
```

See [A command-line interface to difflib](#) for a more detailed example.

`difflib.get_close_matches(word, possibilities, n=3, cutoff=0.6)`

Return a list of the best “good enough” matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to

match *word* (typically a list of strings).

Optional argument *n* (default 3) is the maximum number of close matches to return; *n* must be greater than 0.

Optional argument *cutoff* (default 0.6) is a float in the range [0, 1]. Possibilities that don't score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'pe', 'pale'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('pineapple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

`difflib.ndiff(a, b, linejunk=None, charjunk=IS_CHARACTER_JUNK)`

Compare *a* and *b* (lists of strings); return a **Differ**-style delta (a **generator** generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are filtering functions (or `None`):

*linejunk*: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is `None`. There is also a module-level function **IS\_LINE\_JUNK()**, which filters out lines without visible characters, except for at most one pound character ('#') – however the underlying **SequenceMatcher** class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than using this function.

*charjunk*: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function `IS_CHARACTER_JUNK()`, which filters out whitespace characters (a blank or tab; it's a bad idea to include newline in this!).

`Tools/scripts/ndiff.py` is a command-line front-end to this function.

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keep...
...             'ore\ntree\nemu\n'.splitlines(keep...
>>> print(''.join(diff), end="")
- one
?  ^
+ ore
?  ^
- two
- three
?  -
+ tree
+ emu
```

`difflib.restore(sequence, which)`

Return one of the two sequences that generated a delta.

Given a *sequence* produced by `Differ.compare()` or `ndiff()`, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

Example:

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keep...
...             'ore\ntree\nemu\n'.splitlines(keep...
>>> diff = list(diff) # materialize the generated d
>>> print(''.join	restore(diff, 1)), end="")
one
two
three
```

```
>>> print(''.join(restore(diff, 2)), end="")
ore
tree
emu
```

`difflib.unified_diff(a, b, fromfile=" ", tofile=" ", fromfiledate=" ", tofiledate=" ", n=3, lineterm='\n')`

Compare *a* and *b* (lists of strings); return a [delta](#) (a [generator](#) generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `---`, `+++`, or `@@`) are created with a trailing newline. This is helpful so that inputs created from [io.IOBase.readlines\(\)](#) result in diffs that are suitable for use with [io.IOBase.writelines\(\)](#) since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(unified_diff(s1, s2, fromfile='before.py', tofile='after.py', lineterm=''))
@@ -1,4 +1,4 @@
-bacon
```

```
-eggs
-ham
+python
+eggy
+hamster
guido
```

See [A command-line interface to difflib](#) for a more detailed example.

`difflib.diff_bytes(dfunc, a, b, fromfile=b", tofile=b", fromfiledate=b", tofiledate=b", n=3, lineterm=b\\n')`

Compare *a* and *b* (lists of bytes objects) using *dfunc*; yield a sequence of delta lines (also bytes) in the format returned by *dfunc*. *dfunc* must be a callable, typically either `unified_diff()` or `context_diff()`.

Allows you to compare data with unknown or inconsistent encoding. All inputs except *n* must be bytes objects, not str. Works by losslessly converting all inputs (except *n*) to str, and calling `dfunc(a, b, fromfile, tofile, fromfiledate, tofiledate, n, lineterm)`. The output of *dfunc* is then converted back to bytes, so the delta lines that you receive have the same unknown/inconsistent encodings as *a* and *b*.

*New in version 3.5.*

`difflib.IS_LINE_JUNK(line)`

Return `True` for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single ' # ', otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` in older versions.

`difflib.IS_CHARACTER_JUNK(ch)`

Return `True` for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

See also

**Pattern Matching: The Gestalt Approach** [<https://www.drdobbs.com/database/pattern-matching-the-gestalt-approach/184407970>]

Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in [Dr. Dobb's Journal](#) [<https://www.drdobbs.com/>] in July, 1988.

## SequenceMatcher Objects

The `SequenceMatcher` class has this constructor:

```
class difflib.SequenceMatcher(isjunk = None, a = "", b = "",  
                               autojunk = True)
```

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is “junk” and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: False`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you’re comparing lines as sequences of characters, and don’t want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be [hashable](#).

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

*New in version 3.2:* The *autojunk* parameter.

`SequenceMatcher` objects get three data attributes: *bjunk* is the set of elements of *b* for which *isjunk* is `True`; *bpopular* is the set of non-junk elements considered popular by the

heuristic (if it is not disabled); *b2j* is a dict mapping the remaining elements of *b* to a list of positions where they occur. All three are reset whenever *b* is reset with `set_seqs()` or `set_seq2()`.

*New in version 3.2:* The *bjunk* and *bpopular* attributes.

**SequenceMatcher** objects have the following methods:

`set_seqs(a, b)`

Set the two sequences to be compared.

**SequenceMatcher** computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use `set_seq2()` to set the commonly used sequence once and call `set_seq1()` repeatedly, once for each of the other sequences.

`set_seq1(a)`

Set the first sequence to be compared. The second sequence to be compared is not changed.

`set_seq2(b)`

Set the second sequence to be compared. The first sequence to be compared is not changed.

`find_longest_match(a0=0, ahi=None, b0=0, bhi=None)`

Find longest matching block in `a[a0:ahi]` and `b[b0:bhi]`.

If *isjunk* was omitted or `None`,

`find_longest_match()` returns `(i, j, k)` such that `a[i:i+k]` is equal to `b[j:j+k]`, where `a0 ≤ i ≤ i+k ≤ ahi` and `b0 ≤ j ≤ j+k ≤ bhi`. For all `(i', j', k')` meeting those conditions, the additional conditions `k ≥ k'`, `i ≤ i'`, and if `i == i'`, `j ≤ j'` are also met. In other words, of all maximal matching blocks, return one that starts earliest

in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents ' abcd' from matching the ' abcd' at the tail end of the second sequence directly. Instead only the 'abcd' can match, and matches the leftmost 'abcd' in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns (a1o, b1o, 0).

This method returns a [named tuple](#) Match(a, b, size).

*Changed in version 3.9:* Added default arguments.

### get\_matching\_blocks()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form (i, j, n), and means that `a[i:i+n] == b[j:j+n]`. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value `(len(a), len(b), 0)`. It is the only triple with `n == 0`. If `(i, j, n)` and `(i', j', n')` are adjacent triples in the list, and the second is not the last triple in the list, then `i+n < i'` or `j+n < j'`; in other words, adjacent triples always describe non-adjacent equal blocks.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=
```

`get_opcodes()`

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form `(tag, i1, i2, j1, j2)`. The first tuple has `i1 == j1 == 0`, and remaining tuples have *i1* equal to the *i2* from the preceding tuple, and, likewise, *j1* equal to the previous *j2*.

The *tag* values are strings, with these meanings:

### Meaning

---

`delete` `a[i1:i2]` should be replaced by `b[j1:j2]`.

---

`delete` `a[i1:i2]` should be deleted. Note that `j1 == j2` in this case.

---

`insert` `b[j1:j2]` should be inserted at `a[i1:i1]`. Note that `i1 == i2` in this case.

---

`equal` `a[i1:i2] == b[j1:j2]` (the sub-sequences are equal).

---

For example:

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print('{:7}  a[{:}:{}] --> b[{:}:{}] {!r}'.format(
...         tag, i1, i2, j1, j2, a[i1:i2], b[j1:j2]))
delete  a[0:1] --> b[0:0]      'q' --> ''
equal   a[1:3] --> b[0:2]      'ab' --> 'ab'
```

|         |                   |               |
|---------|-------------------|---------------|
| replace | a[3:4] --> b[2:3] | 'x' --> 'y'   |
| equal   | a[4:6] --> b[3:5] | 'cd' --> 'cd' |
| insert  | a[6:6] --> b[5:6] | ' ' --> 'f'   |

## get\_grouped\_opcodes(*n*=3)

Return a [generator](#) of groups with up to *n* lines of context.

Starting with the groups returned by [get\\_opcodes\(\)](#), this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as [get\\_opcodes\(\)](#).

## ratio()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where *T* is the total number of elements in both sequences, and *M* is the number of matches, this is  $2.0 * M / T$ . Note that this is 1.0 if the sequences are identical, and 0.0 if they have nothing in common.

This is expensive to compute if [get\\_matching\\_blocks\(\)](#) or [get\\_opcodes\(\)](#) hasn't already been called, in which case you may want to try [quick\\_ratio\(\)](#) or [real\\_quick\\_ratio\(\)](#) first to get an upper bound.

### Note

Caution: The result of a [ratio\(\)](#) call may depend on the order of the arguments. For instance:

```
>>> SequenceMatcher(None, 'tide', 'diet').ratio()
0.25
>>> SequenceMatcher(None, 'diet', 'tide').ratio()
0.5
```

`quick_ratio()`

Return an upper bound on `ratio()` relatively quickly.

`real_quick_ratio()`

Return an upper bound on `ratio()` very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although `quick_ratio()` and `real_quick_ratio()` are always at least as large as `ratio()`:

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

## SequenceMatcher Examples

This example compares two strings, considering blanks to be “junk”:

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                       "private Thread currentThread;",
...                       "private volatile Thread current"
```

`ratio()` returns a float in  $[0, 1]$ , measuring the similarity of the sequences. As a rule of thumb, a `ratio()` value over 0.6 means the sequences are close matches:

```
>>> print(round(s.ratio(), 3))
0.866
```

If you’re only interested in where the sequences match, `get_matching_blocks()` is handy:

```
>>> for block in s.get_matching_blocks():
```

```
...     print("a[%d] and b[%d] match for %d elements" %
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by `get_matching_blocks()` is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is 0.

If you want to know how to change the first sequence into the second, use `get_opcodes()`:

```
>>> for opcode in s.get_opcodes():
...     print("%6s a[%d:%d] b[%d:%d]" % opcode)
equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
equal a[8:29] b[17:38]
```

## See also

- The `get_close_matches()` function in this module which shows how simple code building on `SequenceMatcher` can be used to do useful work.
- [Simple version control recipe](https://code.activestate.com/recipes/576729/) [https://code.activestate.com/recipes/576729/] for a small application built with `SequenceMatcher`.

## Differ Objects

Note that `Differ`-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The `Differ` class has this constructor:

`class difflib.Differ(linejunk=None, charjunk=None)`

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or `None`):

*linejunk*: A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

*charjunk*: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

These junk-filtering functions speed up matching to find differences and do not cause any differing lines or characters to be ignored. Read the description of the `find_longest_match()` method's *isjunk* parameter for an explanation.

**Differ** objects are used (deltas generated) via a single method:

`compare(a, b)`

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the `readlines()` method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the `writelines()` method of a file-like object.

## Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the `readlines()` method of file-like objects):

```
>>> text1 = ''' 1. Beautiful is better than ugly.
... 2. Explicit is better than implicit.
... 3. Simple is better than complex.
... 4. Complex is better than complicated.
... '''.splitlines(keepends=True)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = ''' 1. Beautiful is better than ugly.
... 3. Simple is better than complex.
... 4. Complicated is better than complex.
... 5. Flat is better than nested.
... '''.splitlines(keepends=True)
```

Next we instantiate a `Differ` object:

```
>>> d = Differ()
```

Note that when instantiating a `Differ` object we may pass functions to filter out line and character “junk.” See the `Differ()` constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

`result` is a list of strings, so let’s pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
[' 1. Beautiful is better than ugly.\n',
'- 2. Explicit is better than implicit.\n',
'- 3. Simple is better than complex.\n',
'+ 3. Simple is better than complex.\n',
'? ++\n',
'- 4. Complex is better than complicated.\n',
'? ^ ---- ^\n',
'+ 4. Complicated is better than complex.\n',
'? ++++ ^ ^\n',
```

```
'+ 5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
1. Beautiful is better than ugly.
- 2. Explicit is better than implicit.
- 3. Simple is better than complex.
+ 3. Simple is better than complex.
? ++
- 4. Complex is better than complicated.
? ^ ---- ^
+ 4. Complicated is better than complex.
? ++++ ^ ^
+ 5. Flat is better than nested.
```

## A command-line interface to difflib

This example shows how to use difflib to create a diff-like utility. It is also contained in the Python source distribution, as `Tools/scripts/diff.py`.

```
#!/usr/bin/env python3
""" Command line interface to difflib.py providing diffs

* ndiff: lists every line and highlights interline changes
* context: highlights clusters of changes in a before/after style
* unified: highlights clusters of changes in an inline style
* html: generates side by side comparison with color coding

"""

import sys, os, difflib, argparse
from datetime import datetime, timezone

def file_mtime(path):
    t = datetime.fromtimestamp(os.stat(path).st_mtime,
                               timezone.utc)
```

```
        diff = difflib.context_diff(fromlines, tolines,
                                     sys.stdout.writelines(diff)

if __name__ == '__main__':
    main()
```

# textwrap — Text wrapping and filling

Source code: [Lib/textwrap.py](https://github.com/python/cpython/tree/3.11/Lib/textwrap.py) [https://github.com/python/cpython/tree/3.11/Lib/textwrap.py]

---

The `textwrap` module provides some convenience functions, as well as `TextWrapper`, the class that does all the work. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of `TextWrapper` for efficiency.

```
textwrap.wrap(text, width=70, *, initial_indent="",
subsequent_indent="", expand_tabs=True, replace_whitespace=True,
fix_sentence_endings=False, break_long_words=True,
drop_whitespace=True, break_on_hyphens=True, tabsize=8,
max_lines=None, placeholder=' [...]')
```

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below.

See the `TextWrapper.wrap()` method for additional details on how `wrap()` behaves.

```
textwrap.fill(text, width=70, *, initial_indent="", subsequent_indent="",
expand_tabs=True, replace_whitespace=True,
fix_sentence_endings=False, break_long_words=True,
drop_whitespace=True, break_on_hyphens=True, tabsize=8,
max_lines=None, placeholder=' [...]')
```

Wraps the single paragraph in *text*, and returns a single string

containing the wrapped paragraph. `fill()` is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, `fill()` accepts exactly the same keyword arguments as `wrap()`.

```
textwrap.shorten(text, width, *, fix_sentence_endings=False,  
break_long_words=True, break_on_hyphens=True, placeholder=' [...]')
```

Collapse and truncate the given *text* to fit in the given *width*.

First the whitespace in *text* is collapsed (all whitespace is replaced by single spaces). If the result fits in the *width*, it is returned. Otherwise, enough words are dropped from the end so that the remaining words plus the **placeholder** fit within **width**:

```
>>> textwrap.shorten("Hello  world!", width=12)  
'Hello world!'  
>>> textwrap.shorten("Hello  world!", width=11)  
'Hello [...]'  
>>> textwrap.shorten("Hello world", width=10, place  
'Hello...'
```

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below. Note that the whitespace is collapsed before the text is passed to the `TextWrapper fill()` function, so changing the value of `tabsize`, `expand_tabs`, `drop_whitespace`, and `replace_whitespace` will have no effect.

*New in version 3.4.*

```
textwrap.dedent(text)
```

Remove any common leading whitespace from every line in *text*.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines " hello" and "\thello" are considered to have no common leading whitespace.

Lines containing only whitespace are ignored in the input and normalized to a single newline character in the output.

For example:

```
def test():
    # end first line with \ to avoid the empty line
    s = '''\
hello
    world
    '''
    print(repr(s))          # prints '    hello\n
    print(repr(dedent(s))) # prints 'hello\n  worl
```

`textwrap.indent(text, prefix, predicate=None)`

Add *prefix* to the beginning of selected lines in *text*.

Lines are separated by calling `text.splitlines(True)`.

By default, *prefix* is added to all lines that do not consist solely of whitespace (including any line endings).

For example:

```
>>> s = 'hello\n\n \nworld'
>>> indent(s, '  ')
'  hello\n\n \n  world'
```

The optional *predicate* argument can be used to control which lines are indented. For example, it is easy to add *prefix* to even empty and whitespace-only lines:

```
>>> print(indent(s, '+ ', lambda line: True))
+ hello
+
+
```

```
+ world
```

*New in version 3.3.*

`wrap()`, `fill()` and `shorten()` work by creating a `TextWrapper` instance and calling a single method on it. That instance is not reused, so for applications that process many text strings using `wrap()` and/or `fill()`, it may be more efficient to create your own `TextWrapper` object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless `TextWrapper.break_long_words` is set to false.

```
class textwrap.TextWrapper(**kwargs)
```

The `TextWrapper` constructor accepts a number of optional keyword arguments. Each keyword argument corresponds to an instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can re-use the same `TextWrapper` object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The `TextWrapper` instance attributes (and keyword arguments to the constructor) are as follows:

`width`

(default: 70) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than `width`, `TextWrapper` guarantees that no output line will be longer than `width` characters.

## expand\_tabs

(default: `True`) If true, then all tab characters in *text* will be expanded to spaces using the `expandtabs()` method of *text*.

## tabsize

(default: `8`) If `expand_tabs` is true, then all tab characters in *text* will be expanded to zero or more spaces, depending on the current column and the given tab size.

*New in version 3.3.*

## replace\_whitespace

(default: `True`) If true, after tab expansion but before wrapping, the `wrap()` method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

### Note

If `expand_tabs` is false and `replace_whitespace` is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

### Note

If `replace_whitespace` is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using `str.splitlines()` or similar) which are wrapped separately.

## drop\_whitespace

(default: `True`) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

#### `initial_indent`

(default: `' '`) String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

#### `subsequent_indent`

(default: `' '`) String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

#### `fix_sentence_endings`

(default: `False`) If true, `TextWrapper` attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of `'.'`, `'!'`, or `'?'`, possibly followed by one of `'\"'` or `\"'`, followed by a space. One problem with this algorithm is that it is unable to detect the difference between “Dr.” in

```
[...] Dr. Frankenstein's monster [...]
```

and “Spot.” in

```
[...] See Spot. See Spot run [...]
```

`fix_sentence_endings` is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of “lowercase letter”, and a convention of using two spaces after a

period to separate sentences on the same line, it is specific to English-language texts.

#### `break_long_words`

(default: `True`) If true, then words longer than `width` will be broken in order to ensure that no lines are longer than `width`. If it is false, long words will not be broken, and some lines may be longer than `width`. (Long words will be put on a line by themselves, in order to minimize the amount by which `width` is exceeded.)

#### `break_on_hyphens`

(default: `True`) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

#### `max_lines`

(default: `None`) If not `None`, then the output will contain at most `max_lines` lines, with *placeholder* appearing at the end of the output.

*New in version 3.4.*

#### `placeholder`

(default: `' [... ] '`) String that will appear at the end of the output text if it has been truncated.

*New in version 3.4.*

`TextWrapper` also provides some public methods, analogous to the module-level convenience functions:

`wrap(text)`

Wraps the single paragraph in *text* (a string) so every line is at most `width` characters long. All wrapping options are taken from instance attributes of the `TextWrapper` instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

`fill(text)`

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

# unicodedata — Unicode Database

---

This module provides access to the Unicode Character Database (UCD) which defines character properties for all Unicode characters. The data contained in this database is compiled from the [UCD version 14.0.0](https://www.unicode.org/Public/14.0.0/ucd) [https://www.unicode.org/Public/14.0.0/ucd].

The module uses the same names and symbols as defined by Unicode Standard Annex #44, “[Unicode Character Database](https://www.unicode.org/reports/tr44/)” [https://www.unicode.org/reports/tr44/]. It defines the following functions:

`unicodedata.lookup(name)`

Look up character by name. If a character with the given name is found, return the corresponding character. If not found, `KeyError` is raised.

*Changed in version 3.3:* Support for name aliases [1](#) and named sequences [2](#) has been added.

`unicodedata.name(chr[, default])`

Returns the name assigned to the character *chr* as a string. If no name is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.decimal(chr[, default])`

Returns the decimal value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.digit(chr[, default])`

Returns the digit value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, **ValueError** is raised.

`unicodedata.numeric(chr [, default])`

Returns the numeric value assigned to the character *chr* as float. If no such value is defined, *default* is returned, or, if not given, **ValueError** is raised.

`unicodedata.category(chr)`

Returns the general category assigned to the character *chr* as string.

`unicodedata.bidirectional(chr)`

Returns the bidirectional class assigned to the character *chr* as string. If no such value is defined, an empty string is returned.

`unicodedata.combining(chr)`

Returns the canonical combining class assigned to the character *chr* as integer. Returns 0 if no combining class is defined.

`unicodedata.east_asian_width(chr)`

Returns the east asian width assigned to the character *chr* as string.

`unicodedata.mirrored(chr)`

Returns the mirrored property assigned to the character *chr* as integer. Returns 1 if the character has been identified as a “mirrored” character in bidirectional text, 0 otherwise.

`unicodedata.decomposition(chr)`

Returns the character decomposition mapping assigned to the character *chr* as string. An empty string is returned in case no such mapping is defined.

`unicodedata.normalize(form, unistr)`

Return the normal form *form* for the Unicode string *unistr*. Valid values for *form* are ‘NFC’, ‘NFKC’, ‘NFD’, and ‘NFKD’.

The Unicode standard defines various normalization forms of a Unicode string, based on the definition of canonical equivalence and compatibility equivalence. In Unicode, several characters can be expressed in various way. For example, the character U + 00C7 (LATIN CAPITAL LETTER C WITH CEDILLA) can also be expressed as the sequence U + 0043 (LATIN CAPITAL LETTER C) U + 0327 (COMBINING CEDILLA).

For each character, there are two normal forms: normal form C and normal form D. Normal form D (NFD) is also known as canonical decomposition, and translates each character into its decomposed form. Normal form C (NFC) first applies a canonical decomposition, then composes pre-combined characters again.

In addition to these two forms, there are two additional normal forms based on compatibility equivalence. In Unicode, certain characters are supported which normally would be unified with other characters. For example, U + 2160 (ROMAN NUMERAL ONE) is really the same thing as U + 0049 (LATIN CAPITAL LETTER I). However, it is supported in Unicode for compatibility with existing character sets (e.g. gb2312).

The normal form KD (NFKD) will apply the compatibility decomposition, i.e. replace all compatibility characters with their equivalents. The normal form KC (NFKC) first applies the compatibility decomposition, followed by the canonical composition.

Even if two unicode strings are normalized and look the same to a human reader, if one has combining characters and the other doesn't, they may not compare equal.

`unicodedata.is_normalized(form, unistr)`

Return whether the Unicode string *unistr* is in the normal form *form*. Valid values for *form* are ‘NFC’, ‘NFKC’, ‘NFD’, and ‘NFKD’.

*New in version 3.8.*

In addition, the module exposes the following constant:

`unicodedata.unidata_version`

The version of the Unicode database used in this module.

`unicodedata.ucd_3_2_0`

This is an object that has the same methods as the entire module, but uses the Unicode database version 3.2 instead, for applications that require this specific version of the Unicode database (such as IDNA).

**Examples:**

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
'{'
>>> unicodedata.name('/')
'SOLIDUS'
>>> unicodedata.decimal('9')
9
>>> unicodedata.decimal('a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category('A') # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional('\u0660') # 'A'rabic, 'N'umero
'AN'
```

# stringprep — Internet String Preparation

**Source code:** [Lib/stringprep.py](https://github.com/python/cpython/tree/3.11/Lib/stringprep.py) [https://github.com/python/cpython/tree/3.11/Lib/stringprep.py]

---

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for “equality”. Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of “printable” characters.

**RFC 3454** [https://datatracker.ietf.org/doc/html/rfc3454.html] defines a procedure for “preparing” Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the `stringprep` procedure are part of the profile. One example of a `stringprep` profile is `nameprep`, which is used for internationalized domain names.

The module `stringprep` only exposes the tables from **RFC 3454** [https://datatracker.ietf.org/doc/html/rfc3454.html]. As these tables would be very large to represent them as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the `mkstringprep.py` utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC: sets and mappings. For a set, `stringprep` provides the “characteristic function”, i.e. a function that returns `True` if the parameter is part of the set. For mappings, it provides the mapping function: given the key, it returns the associated value. Below is a list of all

functions available in the module.

`stringprep.in_table_a1(code)`

Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

`stringprep.in_table_b1(code)`

Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

`stringprep.map_table_b2(code)`

Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

`stringprep.map_table_b3(code)`

Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

`stringprep.in_table_c11(code)`

Determine whether *code* is in tableC.1.1 (ASCII space characters).

`stringprep.in_table_c12(code)`

Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

`stringprep.in_table_c11_c12(code)`

Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

`stringprep.in_table_c21(code)`

Determine whether *code* is in tableC.2.1 (ASCII control characters).

`stringprep.in_table_c22(code)`

Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

`stringprep.in_table_c21_c22(code)`

Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

`stringprep.in_table_c3(code)`

Determine whether *code* is in tableC.3 (Private use).

`stringprep.in_table_c4(code)`

Determine whether *code* is in tableC.4 (Non-character code points).

`stringprep.in_table_c5(code)`

Determine whether *code* is in tableC.5 (Surrogate codes).

`stringprep.in_table_c6(code)`

Determine whether *code* is in tableC.6 (Inappropriate for plain text).

`stringprep.in_table_c7(code)`

Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

`stringprep.in_table_c8(code)`

Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

`stringprep.in_table_c9(code)`

Determine whether *code* is in tableC.9 (Tagging characters).

`stringprep.in_table_d1(code)`

Determine whether *code* is in tableD.1 (Characters with bidirectional property “R” or “AL”).

`stringprep.in_table_d2(code)`

Determine whether *code* is in tableD.2 (Characters with bidirectional property “L”).

# readline — GNU readline interface

---

The `readline` module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the `rlcompleter` module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter’s interactive prompt and the prompts offered by the built-in `input()` function.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See [Readline Init File](https://tiswww.cwru.edu/php/chet/readline/rluserman.html#Readline-Init-File) [https://tiswww.cwru.edu/php/chet/readline/rluserman.html#Readline-Init-File] in the GNU Readline manual for information about the format and allowable constructs of that file, and the capabilities of the Readline library in general.

## Note

The underlying Readline library API may be implemented by the `libedit` library instead of GNU readline. On macOS the `readline` module detects which library is being used at run time.

The configuration file for `libedit` is different from that of GNU readline. If you programmatically load configuration strings you can check for the text “libedit” in `readline.__doc__` to differentiate between GNU readline and libedit.

If you use `editline/libedit` readline emulation on macOS, the initialization file located in your home directory is named `.editrc`. For example, the following content in `~/.editrc` will turn ON *vi* keybindings and TAB completion:

```
python:bind -v
python:bind ^I rl_complete
```

## Init file

The following functions relate to the init file and user configuration:

`readline.parse_and_bind(string)`

Execute the init line provided in the *string* argument. This calls **rl\_parse\_and\_bind()** in the underlying library.

`readline.read_init_file([filename])`

Execute a readline initialization file. The default filename is the last filename used. This calls **rl\_read\_init\_file()** in the underlying library.

## Line buffer

The following functions operate on the line buffer:

`readline.get_line_buffer()`

Return the current contents of the line buffer (**rl\_line\_buffer** in the underlying library).

`readline.insert_text(string)`

Insert text into the line buffer at the cursor position. This calls **rl\_insert\_text()** in the underlying library, but ignores the return value.

`readline.redisplay()`

Change what's displayed on the screen to reflect the current contents of the line buffer. This calls **rl\_redisplay()** in the underlying library.

## History file

The following functions operate on a history file:

`readline.read_history_file([filename])`

Load a readline history file, and append it to the history list. The default filename is `~/.history`. This calls **`read_history()`** in the underlying library.

`readline.write_history_file([filename])`

Save the history list to a readline history file, overwriting any existing file. The default filename is `~/.history`. This calls **`write_history()`** in the underlying library.

`readline.append_history_file(nelements[, filename])`

Append the last *nelements* items of history to a file. The default filename is `~/.history`. The file must already exist. This calls **`append_history()`** in the underlying library. This function only exists if Python was compiled for a version of the library that supports it.

*New in version 3.5.*

`readline.get_history_length()`

`readline.set_history_length(length)`

Set or return the desired number of lines to save in the history file. The **`write_history_file()`** function uses this value to truncate the history file, by calling **`history_truncate_file()`** in the underlying library. Negative values imply unlimited history file size.

## History list

The following functions operate on a global history list:

`readline.clear_history()`

Clear the current history. This calls **`clear_history()`** in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports

it.

`readline.get_current_history_length()`

Return the number of items currently in the history. (This is different from `get_history_length()`, which returns the maximum number of lines that will be written to a history file.)

`readline.get_history_item(index)`

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

`readline.remove_history_item(pos)`

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

`readline.replace_history_item(pos, line)`

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

`readline.add_history(line)`

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

`readline.set_auto_history(enabled)`

Enable or disable automatic calls to `add_history()` when reading input via readline. The *enabled* argument should be a Boolean value that when true, enables auto history, and that when false, disables auto history.

*New in version 3.6.*

**CPython implementation detail:** Auto history is enabled by default, and changes to this do not persist across multiple

sessions.

## Startup hooks

`readline.set_startup_hook([function])`

Set or remove the function invoked by the **`rl_startup_hook`** callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before `readline` prints the first prompt.

`readline.set_pre_input_hook([function])`

Set or remove the function invoked by the **`rl_pre_input_hook`** callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before `readline` starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

## Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, `Readline` is set up to be used by **`rlcompleter`** to complete Python identifiers for the interactive interpreter. If the **`readline`** module is to be used with a custom completer, a different set of word delimiters should be set.

`readline.set_completer([function])`

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text,`

state), for *state* in 0, 1, 2, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the *entry\_func* callback passed to **rl\_completion\_matches()** in the underlying library. The *text* string comes from the first parameter to the **rl\_attempted\_completion\_function** callback of the underlying library.

**readline.get\_completer()**

Get the completer function, or `None` if no completer function has been set.

**readline.get\_completion\_type()**

Get the type of completion being attempted. This returns the **rl\_completion\_type** variable in the underlying library as an integer.

**readline.get\_begidx()**

**readline.get\_endidx()**

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the **rl\_attempted\_completion\_function** callback of the underlying library. The values may be different in the same input editing scenario based on the underlying C readline implementation. Ex: libedit is known to behave differently than libreadline.

**readline.set\_completer\_delims(*string*)**

**readline.get\_completer\_delims()**

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the **rl\_completer\_word\_break\_characters** variable in the underlying library.

`readline.set_completion_display_matches_hook([function])`

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or `None`, any completion display function already installed is removed. This sets or clears the **`rl_completion_display_matches_hook`** callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

## Example

The following example demonstrates how to use the [readline](#) module's history reading and writing functions to automatically load and save a history file named `.python_history` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's [PYTHONSTARTUP](#) file.

```
import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")
try:
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow large
    readline.set_history_length(1000)
except FileNotFoundError:
    pass

atexit.register(readline.write_history_file, histfile)
```

This code is actually automatically run when Python is run in [interactive mode](#) (see [Readline configuration](#)).

The following example achieves the same goal but supports concurrent interactive sessions, by only appending the new history.

```

import atexit
import os
import readline
histfile = os.path.join(os.path.expanduser("~"), ".python_history")

try:
    readline.read_history_file(histfile)
    h_len = readline.get_current_history_length()
except FileNotFoundError:
    open(histfile, 'wb').close()
    h_len = 0

def save(prev_h_len, histfile):
    new_h_len = readline.get_current_history_length()
    readline.set_history_length(1000)
    readline.append_history_file(new_h_len - prev_h_len, histfile)
atexit.register(save, h_len, histfile)

```

The following example extends the [code.InteractiveConsole](#) class to support history save/restore.

```

import atexit
import code
import os
import readline

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>", histfile=None):
        histfile=os.path.expanduser("~/python_history")
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except FileNotFoundError:
                pass

```

```
        atexit.register(self.save_history, histfile)

def save_history(self, histfile):
    readline.set_history_length(1000)
    readline.write_history_file(histfile)
```

# rlcompleter — Completion function for GNU readline

**Source code:** [Lib/rlcompleter.py](https://github.com/python/cpython/tree/3.11/Lib/rlcompleter.py) [https://github.com/python/cpython/tree/3.11/Lib/rlcompleter.py]

---

The `rlcompleter` module defines a completion function suitable for the `readline` module by completing valid Python identifiers and keywords.

When this module is imported on a Unix platform with the `readline` module available, an instance of the `Completer` class is automatically created and its `complete()` method is set as the `readline` completer.

Example:

```
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer( rea
readline.__file__         readline.insert_text(      rea
readline.__name__         readline.parse_and_bind(
>>> readline.
```

The `rlcompleter` module is designed for use with Python's `interactive mode`. Unless Python is run with the `-S` option, the module is automatically imported and configured (see [Readline configuration](#)).

On platforms without `readline`, the `Completer` class defined by this module can still be used for custom purposes.

# Completer Objects

Completer objects have the following method:

`Completer.complete(text, state)`

Return the *stateth* completion for *text*.

If called for *text* that doesn't include a period character ('.'), it will complete from names currently defined in `__main__`, `builtins` and keywords (as defined by the `keyword` module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to `__getattr__()` up to the last part, and find matches for the rest via the `dir()` function. Any exception raised during the evaluation of the expression is caught, silenced and `None` is returned.

# Binary Data Services

The modules described in this chapter provide some basic services operations for manipulation of binary data. Other operations on binary data, specifically in relation to file formats and network protocols, are described in the relevant sections.

Some libraries described under [Text Processing Services](#) also work with either ASCII-compatible binary formats (for example, [re](#)) or all binary data (for example, [difflib](#)).

In addition, see the documentation for Python’s built-in binary data types in [Binary Sequence Types — bytes, bytearray, memoryview](#).

---

This module converts between Python values and C structs represented as Python **bytes** objects. Compact **format strings** describe the intended conversions to/from Python values. The module's functions and objects can be used for two largely distinct applications, data exchange with external sources (files or network connections), or data transfer between the Python application and the C layer.

## Note

When no prefix character is given, native mode is the default. It packs or unpacks data based on the platform and compiler on which the Python interpreter was built. The result of packing a given C struct includes pad bytes which maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. In contrast, when communicating data between external sources, the programmer is responsible for defining byte ordering and padding between elements. See [Byte Order, Size, and Alignment](#) for details.

Several **struct** functions (and methods of **Struct**) take a *buffer* argument. This refers to objects that implement the [Buffer Protocol](#) and provide either a readable or read-writable buffer. The most common types used for that purpose are **bytes** and **bytearray**, but many other types that can be viewed as an array of bytes implement the buffer protocol, so that they can be read/filled without additional copying from a **bytes** object.

# Functions and Exceptions

The module defines the following exception and functions:

*exception* struct.error

Exception raised on various occasions; argument is a string describing what is wrong.

struct.pack(*format*, *v1*, *v2*, ...)

Return a bytes object containing the values *v1*, *v2*, ... packed according to the format string *format*. The arguments must match the values required by the format exactly.

struct.pack\_into(*format*, *buffer*, *offset*, *v1*, *v2*, ...)

Pack the values *v1*, *v2*, ... according to the format string *format* and write the packed bytes into the writable buffer *buffer* starting at position *offset*. Note that *offset* is a required argument.

struct.unpack(*format*, *buffer*)

Unpack from the buffer *buffer* (presumably packed by `pack(format, ...)`) according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes must match the size required by the format, as reflected by `calcsize()`.

struct.unpack\_from(*format*, */*, *buffer*, *offset*=0)

Unpack from *buffer* starting at position *offset*, according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes, starting at position *offset*, must be at least the size required by the format, as reflected by `calcsize()`.

struct.iter\_unpack(*format*, *buffer*)

Iteratively unpack from the buffer *buffer* according to the format string *format*. This function returns an iterator which will read equally sized chunks from the buffer until all its

contents have been consumed. The buffer's size in bytes must be a multiple of the size required by the format, as reflected by `calcsize()`.

Each iteration yields a tuple as specified by the format string.

*New in version 3.4.*

`struct.calcsize(format)`

Return the size of the struct (and hence of the bytes object produced by `pack(format, ...)`) corresponding to the format string *format*.

## Format Strings

Format strings describe the data layout when packing and unpacking data. They are built up from [format characters](#), which specify the type of data being packed/unpacked. In addition, special characters control the [byte order, size and alignment](#). Each format string consists of an optional prefix character which describes the overall properties of the data and one or more format characters which describe the actual data values and padding.

### Byte Order, Size, and Alignment

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler). This behavior is chosen so that the bytes of a packed struct correspond exactly to the memory layout of the corresponding C struct. Whether to use native byte ordering and padding or standard formats depends on the application.

Alternatively, the first character of the format string can be used to indicate the byte order, size and alignment of the packed data, according to the following table:

| Alignment |
|-----------|
|-----------|

|        |
|--------|
| Native |
|--------|

|                                    |
|------------------------------------|
| <del>standard</del>                |
| <del>little-endian</del>           |
| <del>big-endian</del>              |
| <del>standard (= big-endian)</del> |

If the first character is not one of these, '@' is assumed.

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86, AMD64 (x86-64), and Apple M1 are little-endian; IBM z and many legacy architectures are big-endian. Use `sys.byteorder` to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character; see the table in the [Format Characters](#) section.

Note the difference between '@' and '=': both use native byte order, but the size and alignment of the latter is standardized.

The form '!' represents the network byte order which is always big-endian as defined in [IETF RFC 1700](https://datatracker.ietf.org/doc/html/rfc1700) [https://datatracker.ietf.org/doc/html/rfc1700].

There is no way to indicate non-native byte order (force byte-swapping); use the appropriate choice of '<' or '>'.

Notes:

1. Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.
2. No padding is added when using non-native size and alignment, e.g. with '<', '>', '=', and '!'.
3. To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See [Examples](#).

# Format Characters

Format characters have the following meaning; the conversion between C and Python values should be obvious given their types. The ‘Standard size’ column refers to the size of the packed value in bytes when using standard size; that is, when the format string starts with one of ‘<’, ‘>’, ‘!’ or ‘=’. When using native size, the size of the packed value is platform-dependent.

| Basic type       | Size     |
|------------------|----------|
| bool             | 1 byte   |
| char             | 1 byte   |
| signed char      | 1 byte   |
| short            | 2 bytes  |
| signed short     | 2 bytes  |
| int              | 4 bytes  |
| signed int       | 4 bytes  |
| long             | 4 bytes  |
| signed long      | 4 bytes  |
| long long        | 8 bytes  |
| signed long long | 8 bytes  |
| float            | 4 bytes  |
| double           | 8 bytes  |
| long double      | 16 bytes |
| char*            | 8 bytes  |
| int*             | 8 bytes  |
| long*            | 8 bytes  |
| float*           | 8 bytes  |
| double*          | 8 bytes  |
| long double*     | 16 bytes |

*Changed in version 3.3:* Added support for the 'n' and 'N' formats.

*Changed in version 3.6:* Added support for the 'e' format.

Notes:

1. The `'?'` conversion code corresponds to the `_Bool` type defined by C99. If this type is not available, it is simulated

using a char. In standard mode, it is always represented by one byte.

2. When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a [\\_\\_index\\_\\_\(\)](#) method then that method is called to convert the argument to an integer before packing.

*Changed in version 3.2:* Added use of the [\\_\\_index\\_\\_\(\)](#) method for non-integers.

3. The 'n' and 'N' conversion codes are only available for the native size (selected as the default or with the '@' byte order character). For the standard size, you can use whichever of the other integer formats fits your application.
4. For the 'f', 'd' and 'e' conversion codes, the packed representation uses the IEEE 754 binary32, binary64 or binary16 format (for 'f', 'd' or 'e' respectively), regardless of the floating-point format used by the platform.
5. The 'P' format character is only available for the native byte ordering (selected as the default or with the '@' byte order character). The byte order character '=' chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the 'P' format is not available.
6. The IEEE 754 binary16 “half precision” type was introduced in the 2008 revision of the [IEEE 754 standard](https://en.wikipedia.org/wiki/IEEE_754-2008_revision) [https://en.wikipedia.org/wiki/IEEE\_754-2008\_revision]. It has a sign bit, a 5-bit exponent and 11-bit precision (with 10 bits explicitly stored), and can represent numbers between approximately  $6.1\text{e-}05$  and  $6.5\text{e}+04$  at full precision. This type is not widely supported by C compilers: on a typical machine, an unsigned short can be used for storage, but not for math operations. See the Wikipedia page on the [half-precision floating-point format](https://en.wikipedia.org/wiki/Half-precision_floating-point_format) [https://en.wikipedia.org/wiki/Half-precision\_floating-point\_format] for more information.
7. When packing, 'x' inserts one NUL byte.

8. The `'p'` format character encodes a “Pascal string”, meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to `pack()` is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it is padded with null bytes so that exactly count bytes in all are used. Note that for `unpack()`, the `'p'` format character consumes `count` bytes, but that the string returned can never contain more than 255 bytes.
9. For the `'s'` format character, the count is interpreted as the length of the bytes, not a repeat count like for the other format characters; for example, `'10s'` means a single 10-byte string mapping to or from a single Python byte string, while `'10c'` means 10 separate one byte character elements (e.g., `cccccccccc`) mapping to or from ten different Python byte objects. (See [Examples](#) for a concrete demonstration of the difference.) If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting bytes object always has exactly the specified number of bytes. As a special case, `'0s'` means a single, empty string (while `'0c'` means 0 characters).

A format character may be preceded by an integral repeat count. For example, the format string `'4h'` means exactly the same as `'hhhh'`.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

When packing a value `x` using one of the integer formats (`'b'`, `'B'`, `'h'`, `'H'`, `'i'`, `'I'`, `'l'`, `'L'`, `'q'`, `'Q'`), if `x` is outside the valid range for that format then `struct.error` is raised.

*Changed in version 3.1:* Previously, some of the integer formats wrapped out-of-range values and raised `DeprecationWarning` instead of `struct.error`.

For the '?' format character, the return value is either **True** or **False**. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be **True** when unpacking.

## Examples

### Note

Native byte order examples (designated by the '@' format prefix or lack of any prefix character) may not match what the reader's machine produces as that depends on the platform and compiler.

Pack and unpack integers of three different sizes, using big endian ordering:

```
>>> from struct import *
>>> pack(">bhl", 1, 2, 3)
b'\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('>bhl', b'\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('>bhl')
7
```

Attempt to pack an integer which is too large for the defined field:

```
>>> pack(">h", 99999)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
struct.error: 'h' format requires -32768 <= number <= 32767
```

Demonstrate the difference between 's' and 'c' format characters:

```
>>> pack("@ccc", b'1', b'2', b'3')
b'123'
>>> pack("@3s", b'123')
b'123'
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple:

```
>>> record = b'raymond    \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name=b'raymond    ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size in native mode since padding is implicit. In standard mode, the user is responsible for inserting any desired padding. Note in the first pack call below that three NUL bytes were added after the packed '#' to align the following integer on a four-byte boundary. In this example, the output was produced on a little endian machine:

```
>>> pack('@ci', b'##', 0x12131415)
b'#\x00\x00\x00\x15\x14\x13\x12'
>>> pack('@ic', 0x12131415, b'##')
b'\x15\x14\x13\x12##'
>>> calcsizesize('@ci')
8
>>> calcsizesize('@ic')
5
```

The following format 'llh01' results in two pad bytes being added at the end, assuming the platform's longs are aligned on 4-byte boundaries:

```
>>> pack('@llh01', 1, 2, 3)
b'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

## Applications

Two main applications for the `struct` module exist, data interchange between Python and C code within an application or another application compiled using the same compiler (`native formats`), and data interchange between applications using agreed upon data layout (`standard formats`). Generally speaking, the format strings constructed for these two domains are distinct.

### Native Formats

When constructing format strings which mimic native layouts, the compiler and machine architecture determine byte ordering and padding. In such cases, the `@` format character should be used to specify native byte ordering and data sizes. Internal pad bytes are normally inserted automatically. It is possible that a zero-repeat format code will be needed at the end of a format string to round up to the correct byte boundary for proper alignment of consecutive chunks of data.

Consider these two simple examples (on a 64-bit, little-endian machine):

```
>>> calcsize('@hl')
24
>>> calcsize('@llh')
18
```

Data is not padded to an 8-byte boundary at the end of the second format string without the use of extra padding. A zero-repeat format code solves that problem:

```
>>> calcsize('@llh0l')
24
```

The 'x' format code can be used to specify the repeat, but for native formats it is better to use a zero-repeat format like '01'.

By default, native byte ordering and alignment is used, but it is better to be explicit and use the '@' prefix character.

## Standard Formats

When exchanging data beyond your process such as networking or storage, be precise. Specify the exact byte order, size, and alignment. Do not assume they match the native order of a particular machine. For example, network byte order is big-endian, while many popular CPUs are little-endian. By defining this explicitly, the user need not care about the specifics of the platform their code is running on. The first character should typically be < or > (or !). Padding is the responsibility of the programmer. The zero-repeat format character won't work. Instead, the user must explicitly add 'x' pad bytes where needed. Revisiting the examples from the previous section, we have:

```
>>> calcsz('<qh6xq')
24
>>> pack('<qh6xq', 1, 2, 3) == pack('@lh1', 1, 2, 3)
True
>>> calcsz('@llh')
18
>>> pack('@llh', 1, 2, 3) == pack('<qqh', 1, 2, 3)
True
>>> calcsz('<qqh6x')
24
>>> calcsz('@llh01')
24
>>> pack('@llh01', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
True
```

The above results (executed on a 64-bit machine) aren't guaranteed to match when executed on different machines. For example, the examples below were executed on a 32-bit machine:

```
>>> calcsz('<qqh6x')
```

```
24
>>> calcsizes('@llh0l')
12
>>> pack('@llh0l', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
False
```

## Classes

The **struct** module also defines the following type:

*class struct.Struct(format)*

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling module-level functions with the same format since the format string is only compiled once.

### Note

The compiled versions of the most recent format strings passed to **Struct** and the module-level functions are cached, so programs that use only a few format strings needn't worry about reusing a single **Struct** instance.

Compiled Struct objects support the following methods and attributes:

*pack(v1, v2, ...)*

Identical to the **pack()** function, using the compiled format. (`len(result)` will equal **size**.)

*pack\_into(buffer, offset, v1, v2, ...)*

Identical to the **pack\_into()** function, using the compiled format.

*unpack(buffer)*

Identical to the **unpack()** function, using the

compiled format. The buffer's size in bytes must equal **size**.

`unpack_from(buffer, offset=0)`

Identical to the `unpack_from()` function, using the compiled format. The buffer's size in bytes, starting at position *offset*, must be at least **size**.

`iter_unpack(buffer)`

Identical to the `iter_unpack()` function, using the compiled format. The buffer's size in bytes must be a multiple of **size**.

*New in version 3.4.*

**format**

The format string used to construct this Struct object.

*Changed in version 3.7:* The format string type is now **str** instead of **bytes**.

**size**

The calculated size of the struct (and hence of the bytes object produced by the `pack()` method) corresponding to **format**.

# codecs — Codec registry and base classes

**Source code:** [Lib/codecs.py](https://github.com/python/cpython/tree/3.11/Lib/codecs.py) [https://github.com/python/cpython/tree/3.11/Lib/codecs.py]

---

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry, which manages the codec and error handling lookup process. Most standard codecs are [text encodings](#), which encode text to bytes (and decode bytes to text), but there are also codecs provided that encode text to text, and bytes to bytes. Custom codecs may encode and decode between arbitrary types, but some module features are restricted to be used specifically with [text encodings](#) or with codecs that encode to [bytes](#).

The module defines the following functions for encoding and decoding with any codec:

`codecs.encode(obj, encoding='utf-8', errors='strict')`

Encodes *obj* using the codec registered for *encoding*.

*Errors* may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that encoding errors raise [ValueError](#) (or a more codec specific subclass, such as [UnicodeEncodeError](#)). Refer to [Codec Base Classes](#) for more information on codec error handling.

`codecs.decode(obj, encoding='utf-8', errors='strict')`

Decodes *obj* using the codec registered for *encoding*.

*Errors* may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that decoding errors raise [ValueError](#) (or a more codec specific

subclass, such as `UnicodeDecodeError`). Refer to [Codec Base Classes](#) for more information on codec error handling.

The full details for each codec can also be looked up directly:

`codecs.lookup(encoding)`

Looks up the codec info in the Python codec registry and returns a `CodecInfo` object as defined below.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no `CodecInfo` object is found, a `LookupError` is raised. Otherwise, the `CodecInfo` object is stored in the cache and returned to the caller.

```
class codecs.CodecInfo(encode, decode, streamreader = None,  
streamwriter = None, incrementalencoder = None,  
incrementaldecoder = None, name = None)
```

Codec details when looking up the codec registry. The constructor arguments are stored in attributes of the same name:

`name`

The name of the encoding.

`encode`

`decode`

The stateless encoding and decoding functions. These must be functions or methods which have the same interface as the `encode()` and `decode()` methods of Codec instances (see [Codec Interface](#)). The functions or methods are expected to work in a stateless mode.

`incrementalencoder`

`incrementaldecoder`

Incremental encoder and decoder classes or factory functions. These have to provide the interface defined by the base classes `IncrementalEncoder` and

**IncrementalDecoder**, respectively. Incremental codecs can maintain state.

streamwriter  
streamreader

Stream writer and reader classes or factory functions. These have to provide the interface defined by the base classes **StreamWriter** and **StreamReader**, respectively. Stream codecs can maintain state.

To simplify access to the various codec components, the module provides these additional functions which use **lookup()** for the codec lookup:

`codecs.getencoder(encoding)`

Look up the codec for the given encoding and return its encoder function.

Raises a **LookupError** in case the encoding cannot be found.

`codecs.getdecoder(encoding)`

Look up the codec for the given encoding and return its decoder function.

Raises a **LookupError** in case the encoding cannot be found.

`codecs.getincrementalencoder(encoding)`

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a **LookupError** in case the encoding cannot be found or the codec doesn't support an incremental encoder.

`codecs.getincrementaldecoder(encoding)`

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a **LookupError** in case the encoding cannot be found or the codec doesn't support an incremental decoder.

`codecs.getreader(encoding)`

Look up the codec for the given encoding and return its **StreamReader** class or factory function.

Raises a **LookupError** in case the encoding cannot be found.

`codecs.getwriter(encoding)`

Look up the codec for the given encoding and return its **StreamWriter** class or factory function.

Raises a **LookupError** in case the encoding cannot be found.

Custom codecs are made available by registering a suitable codec search function:

`codecs.register(search_function)`

Register a codec search function. Search functions are expected to take one argument, being the encoding name in all lower case letters with hyphens and spaces converted to underscores, and return a **CodecInfo** object. In case a search function cannot find a given encoding, it should return `None`.

*Changed in version 3.9:* Hyphens and spaces are converted to underscore.

`codecs.unregister(search_function)`

Unregister a codec search function and clear the registry's cache. If the search function is not registered, do nothing.

*New in version 3.10.*

While the builtin `open()` and the associated `io` module are the

recommended approach for working with encoded text files, this module provides additional utility functions and classes that allow the use of a wider range of codecs when working with binary files:

```
codecs.open(filename, mode='r', encoding=None, errors='strict',  
buffering=-1)
```

Open an encoded file using the given *mode* and return an instance of **StreamReaderWriter**, providing transparent encoding/decoding. The default file mode is `'r'`, meaning to open the file in read mode.

### Note

If *encoding* is not `None`, then the underlying encoded files are always opened in binary mode. No automatic conversion of `'\n'` is done on reading and writing. The *mode* argument may be any binary mode acceptable to the built-in **open()** function; the `'b'` is automatically added.

*encoding* specifies the encoding which is to be used for the file. Any encoding that encodes to and decodes from bytes is allowed, and the data types supported by the file methods depend on the codec used.

*errors* may be given to define the error handling. It defaults to `'strict'` which causes a **ValueError** to be raised in case an encoding error occurs.

*buffering* has the same meaning as for the built-in **open()** function. It defaults to `-1` which means that the default buffer size will be used.

*Changed in version 3.11:* The `'U'` mode has been removed.

```
codecs.EncodedFile(file, data_encoding, file_encoding=None,  
errors='strict')
```

Return a **StreamRecoder** instance, a wrapped version of *file* which provides transparent transcoding. The original file is

closed when the wrapped version is closed.

Data written to the wrapped file is decoded according to the given *data\_encoding* and then written to the original file as bytes using *file\_encoding*. Bytes read from the original file are decoded according to *file\_encoding*, and the result is encoded using *data\_encoding*.

If *file\_encoding* is not given, it defaults to *data\_encoding*.

*errors* may be given to define the error handling. It defaults to 'strict', which causes **ValueError** to be raised in case an encoding error occurs.

`codecs.iterencode(iterator, encoding, errors='strict', **kwargs)`

Uses an incremental encoder to iteratively encode the input provided by *iterator*. This function is a **generator**. The *errors* argument (as well as any other keyword argument) is passed through to the incremental encoder.

This function requires that the codec accept text **str** objects to encode. Therefore it does not support bytes-to-bytes encoders such as `base64_codec`.

`codecs.iterdecode(iterator, encoding, errors='strict', **kwargs)`

Uses an incremental decoder to iteratively decode the input provided by *iterator*. This function is a **generator**. The *errors* argument (as well as any other keyword argument) is passed through to the incremental decoder.

This function requires that the codec accept **bytes** objects to decode. Therefore it does not support text-to-text encoders such as `rot_13`, although `rot_13` may be used equivalently with **`iterencode()`**.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

`codecs.BOM`  
`codecs.BOM_BE`

```
codecs.BOM_LE
codecs.BOM_UTF8
codecs.BOM_UTF16
codecs.BOM_UTF16_BE
codecs.BOM_UTF16_LE
codecs.BOM_UTF32
codecs.BOM_UTF32_BE
codecs.BOM_UTF32_LE
```

These constants define various byte sequences, being Unicode byte order marks (BOMs) for several encodings. They are used in UTF-16 and UTF-32 data streams to indicate the byte order used, and in UTF-8 as a Unicode signature.

`BOM_UTF16` is either `BOM_UTF16_BE` or `BOM_UTF16_LE` depending on the platform's native byte order, `BOM` is an alias for `BOM_UTF16`, `BOM_LE` for `BOM_UTF16_LE` and `BOM_BE` for `BOM_UTF16_BE`. The others represent the BOM in UTF-8 and UTF-32 encodings.

## Codec Base Classes

The `codecs` module defines a set of base classes which define the interfaces for working with codec objects, and can also be used as the basis for custom codec implementations.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols. Codec authors also need to define how the codec will handle encoding and decoding errors.

## Error Handlers

To simplify and standardize error handling, codecs may implement different error handling schemes by accepting the *errors* string argument:

```
>>> 'German ß, ð'.encode(encoding='ascii', errors='backslash')
b'German \\xdf, \\u266c'
```

```
>>> 'German ß, ʃ'.encode(encoding='ascii', errors='xmlcharrefreplace')
b'German &#223;, &#9836;'
```

The following error handlers can be used with all Python [Standard Encodings](#) codecs:

### Warning

---

Raise a [UnicodeError](#) (or a subclass), this is the default.

Implemented in [strict\\_errors\(\)](#).

---

Ignore the malformed data and continue without further notice.

Implemented in [ignore\\_errors\(\)](#).

---

Replace with a replacement marker. On encoding, use `?` (ASCII character). On decoding, use `�` (U+FFFD, the official REPLACEMENT CHARACTER). Implemented in

[replace\\_errors\(\)](#).

---

Replace with backslashed escape sequences. On encoding, use hexadecimal form of Unicode code point with formats `\xhh`, `\uxxxx`, `\Uxxxxxxxxxx`. On decoding, use hexadecimal form of byte value with format `\xhh`. Implemented in

[backslashreplace\\_errors\(\)](#).

---

On decoding, replace byte with individual surrogate code ranging from U+DC80 to U+DCFF. This code will then be turned back into the same byte when the `'surrogateescape'` error handler is used when encoding the data. (See [PEP 383](#) for more.)

---

The following error handlers are only applicable to encoding (within [text encodings](#)):

### Warning

---

Replace with XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;`

Implemented in [xmlcharrefreplace\\_errors\(\)](#).

---

Replace with `&N{...}` escape sequences, what appears in the braces is the Name property from Unicode Character Database.

Implemented in [namereplace\\_errors\(\)](#).

---

In addition, the following error handler is specific to the given codecs:

### Warning

---

All SymPy coding and decoding, surrogate, code point (U+3200 - U

---

+DFFF) as normal code point. Otherwise these codecs treat the presence of surrogate code point in `str` as an error.

---

*New in version 3.1:* The `'surrogateescape'` and `'surrogatepass'` error handlers.

*Changed in version 3.4:* The `'surrogatepass'` error handler now works with utf-16\* and utf-32\* codecs.

*New in version 3.5:* The `'namereplace'` error handler.

*Changed in version 3.5:* The `'backslashreplace'` error handler now works with decoding and translating.

The set of allowed values can be extended by registering a new named error handler:

`codecs.register_error(name, error_handler)`

Register the error handling function `error_handler` under the name `name`. The `error_handler` argument will be called during encoding and decoding in case of an error, when `name` is specified as the errors parameter.

For encoding, `error_handler` will be called with a `UnicodeEncodeError` instance, which contains information about the location of the error. The error handler must either raise this or a different exception, or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The replacement may be either `str` or `bytes`. If the replacement is bytes, the encoder will simply copy them into the output buffer. If the replacement is a string, the encoder will encode the replacement. Encoding continues on original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an `IndexError` will be raised.

Decoding and translating works similarly, except `UnicodeDecodeError` or `UnicodeTranslateError` will be passed to the handler and that the replacement from the error handler will be put into the output directly.

Previously registered error handlers (including the standard error handlers) can be looked up by name:

`codecs.lookup_error(name)`

Return the error handler previously registered under the name *name*.

Raises a [LookupError](#) in case the handler cannot be found.

The following standard error handlers are also made available as module level functions:

`codecs.strict_errors(exception)`

Implements the 'strict' error handling.

Each encoding or decoding error raises a [UnicodeError](#).

`codecs.ignore_errors(exception)`

Implements the 'ignore' error handling.

Malformed data is ignored; encoding or decoding is continued without further notice.

`codecs.replace_errors(exception)`

Implements the 'replace' error handling.

Substitutes ? (ASCII character) for encoding errors or  (U+FFFD, the official REPLACEMENT CHARACTER) for decoding errors.

`codecs.backslashreplace_errors(exception)`

Implements the 'backslashreplace' error handling.

Malformed data is replaced by a backslashed escape sequence. On encoding, use the hexadecimal form of Unicode code point with formats `\xhh` `\uxxxx` `\Uxxxxxxxx`. On decoding, use the hexadecimal form of byte value with format `\xhh`.

*Changed in version 3.5:* Works with decoding and translating.

`codecs.xmlcharrefreplace_errors(exception)`

Implements the 'xmlcharrefreplace' error handling (for encoding within [text encoding](#) only).

The unencodable character is replaced by an appropriate XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;` .

`codecs.namereplace_errors(exception)`

Implements the 'namereplace' error handling (for encoding within [text encoding](#) only).

The unencodable character is replaced by a `\N{...}` escape sequence. The set of characters that appear in the braces is the Name property from Unicode Character Database. For example, the German lowercase letter 'ß' will be converted to byte sequence `\N{LATIN SMALL LETTER SHARP S}` .

*New in version 3.5.*

## Stateless Encoding and Decoding

The base **Codec** class defines these methods which also define the function interfaces of the stateless encoder and decoder:

`Codec.encode(input, errors='strict')`

Encodes the object *input* and returns a tuple (output object, length consumed). For instance, [text encoding](#) converts a string object to a bytes object using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the **Codec** instance. Use [StreamWriter](#) for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

`Codec.decode(input, errors = 'strict')`

Decodes the object *input* and returns a tuple (output object, length consumed). For instance, for a [text encoding](#), decoding converts a bytes object encoded using a particular character set encoding to a string object.

For text encodings and bytes-to-bytes codecs, *input* must be a bytes object or one which provides the read-only buffer interface – for example, buffer objects and memory mapped files.

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the **Codec** instance. Use [StreamReader](#) for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

## Incremental Encoding and Decoding

The [IncrementalEncoder](#) and [IncrementalDecoder](#) classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the [encode\(\)](#)/[decode\(\)](#) method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the [encode\(\)](#)/[decode\(\)](#) method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

## IncrementalEncoder Objects

The `IncrementalEncoder` class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

`class codecs.IncrementalEncoder(errors = 'strict')`

Constructor for an `IncrementalEncoder` instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The `IncrementalEncoder` may implement different error handling schemes by providing the `errors` keyword argument. See [Error Handlers](#) for possible values.

The `errors` argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `IncrementalEncoder` object.

`encode(object, final = False)`

Encodes `object` (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to `encode()` `final` must be true (the default is false).

`reset()`

Reset the encoder to the initial state. The output is discarded: call `.encode(object, final=True)`, passing an empty byte or text string if necessary, to reset the encoder and to get the output.

`getstate()`

Return the current state of the encoder which must be an integer. The implementation should make sure that

0 is the most common state. (States that are more complicated than integers can be converted into an integer by marshaling/pickling the state and encoding the bytes of the resulting string into an integer.)

`setstate(state)`

Set the state of the encoder to *state*. *state* must be an encoder state returned by `getstate()`.

## IncrementalDecoder Objects

The `IncrementalDecoder` class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

`class codecs.IncrementalDecoder(errors='strict')`

Constructor for an `IncrementalDecoder` instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The `IncrementalDecoder` may implement different error handling schemes by providing the *errors* keyword argument. See [Error Handlers](#) for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `IncrementalDecoder` object.

`decode(object, final=False)`

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to `decode()` *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers.

If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

`reset()`

Reset the decoder to the initial state.

`getstate()`

Return the current state of the decoder. This must be a tuple with two items, the first must be the buffer containing the still undecoded input. The second must be an integer and can be additional state info. (The implementation should make sure that 0 is the most common additional state info.) If this additional state info is 0 it must be possible to set the decoder to the state which has no input buffered and 0 as the additional state info, so that feeding the previously buffered input to the decoder returns it to the previous state without producing any output. (Additional state info that is more complicated than integers can be converted into an integer by marshaling/pickling the info and encoding the bytes of the resulting string into an integer.)

`setstate(state)`

Set the state of the decoder to *state*. *state* must be a decoder state returned by `getstate()`.

## Stream Encoding and Decoding

The `StreamWriter` and `StreamReader` classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

### StreamWriter Objects

The `StreamWriter` class is a subclass of `Codec` and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

`class codecs.StreamWriter(stream, errors = 'strict')`

Constructor for a `StreamWriter` instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for writing text or binary data, as appropriate for the specific codec.

The `StreamWriter` may implement different error handling schemes by providing the *errors* keyword argument. See [Error Handlers](#) for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamWriter` object.

`write(object)`

Writes the object's contents encoded to the stream.

`writelines(list)`

Writes the concatenated iterable of strings to the stream (possibly by reusing the `write()` method). Infinite or very large iterables are not supported. The standard bytes-to-bytes codecs do not support this method.

`reset()`

Resets the codec buffers used for keeping internal state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of

new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the `StreamWriter` must also inherit all other methods and attributes from the underlying stream.

## StreamReader Objects

The `StreamReader` class is a subclass of `Codec` and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

`class codecs.StreamReader(stream, errors = 'strict')`

Constructor for a `StreamReader` instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for reading text or binary data, as appropriate for the specific codec.

The `StreamReader` may implement different error handling schemes by providing the *errors* keyword argument. See [Error Handlers](#) for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamReader` object.

The set of allowed values for the *errors* argument can be extended with `register_error()`.

`read(size = - 1, chars = - 1, firstline = False)`

Decodes data from the stream and returns the resulting object.

The *chars* argument indicates the number of decoded code points or bytes to return. The `read()` method will never return more data than requested, but it might return less, if there is not enough available.

The *size* argument indicates the approximate maximum number of encoded bytes or code points to read for decoding. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. This parameter is intended to prevent having to decode huge files in one step.

The *firstline* flag indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

`readline(size=None, keepends=True)`

Read one line from the input stream and return the decoded data.

*size*, if given, is passed as size argument to the stream's `read()` method.

If *keepends* is false line-endings will be stripped from the lines returned.

`readlines(sizehint=None, keepends=True)`

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's `decode()` method and are included in the list entries if *keepends* is true.

*sizehint*, if given, is passed as the *size* argument to the stream's `read()` method.

`reset()`

Resets the codec buffers used for keeping internal state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the `StreamReader` must also inherit all other methods and attributes from the underlying stream.

## StreamReaderWriter Objects

The `StreamReaderWriter` is a convenience class that allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the `lookup()` function to construct the instance.

```
class codecs.StreamReaderWriter(stream, Reader, Writer,  
errors='strict')
```

Creates a `StreamReaderWriter` instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the `StreamReader` and `StreamWriter` interface resp. Error handling is done in the same way as defined for the stream readers and writers.

`StreamReaderWriter` instances define the combined interfaces of `StreamReader` and `StreamWriter` classes. They inherit all other methods and attributes from the underlying stream.

## StreamRecoder Objects

The `StreamRecoder` translates data from one encoding to another, which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the `lookup()` function to construct the instance.

```
class codecs.StreamRecoder(stream, encode, decode, Reader, Writer,  
errors = 'strict')
```

Creates a `StreamRecoder` instance which implements a two-way conversion: *encode* and *decode* work on the frontend — the data visible to code calling `read()` and `write()`, while *Reader* and *Writer* work on the backend — the data in *stream*.

You can use these objects to do transparent transcodings, e.g., from Latin-1 to UTF-8 and back.

The *stream* argument must be a file-like object.

The *encode* and *decode* arguments must adhere to the `Codec` interface. *Reader* and *Writer* must be factory functions or classes providing objects of the `StreamReader` and `StreamWriter` interface respectively.

Error handling is done in the same way as defined for the stream readers and writers.

`StreamRecoder` instances define the combined interfaces of `StreamReader` and `StreamWriter` classes. They inherit all other methods and attributes from the underlying stream.

## Encodings and Unicode

Strings are stored internally as sequences of code points in range U+0000–U+10FFFF. (See [PEP 393](https://peps.python.org/pep-0393/) [https://peps.python.org/pep-0393/] for more details about the implementation.) Once a string object is used outside of CPU and memory, endianness and how these arrays are stored as bytes become an issue. As with other codecs, serialising a string into a sequence of bytes is known as *encoding*, and recreating the string from the sequence of bytes is known as *decoding*. There are a variety of different text serialisation codecs, which are collectively referred to as [text encodings](#).

The simplest text encoding (called `'latin-1'` or `'iso-8859-1'`) maps the code points 0–255 to the bytes `0x0–0xff`, which means that a string object that contains code points above `U+00FF` can't be encoded with this codec. Doing so will raise a `UnicodeEncodeError` that looks like the following (although the details of the error message may differ):

```
UnicodeEncodeError: 'latin-1' codec can't encode
character '\u1234' in position 3: ordinal not in
range(256).
```

There's another group of encodings (the so called charmap encodings) that choose a different subset of all Unicode code points and how these code points are mapped to the bytes `0x0–0xff`. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in Unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called `UTF-32-BE` and `UTF-32-LE` respectively. Their disadvantage is that if e.g. you use `UTF-32-BE` on a little endian machine you will always have to swap bytes on encoding and decoding. `UTF-32` avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a `UTF-16` or `UTF-32` byte sequence, there's the so called BOM ("Byte Order Mark"). This is the Unicode character `U+FEFF`. This character can be prepended to every `UTF-16` or `UTF-32` byte sequence. The byte swapped version of this character (`0xFFFE`) is an illegal character that may not appear in a Unicode text. So when the first character in a `UTF-16` or `UTF-32` byte sequence appears to be a `U+FFFE` the bytes have to be swapped on decoding. Unfortunately the character `U+FEFF` had a second purpose as a `ZERO WIDTH NO-BREAK SPACE`: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using `U`

+FEFF as a ZERO WIDTH NO-BREAK SPACE has been deprecated (with U+2060 (WORD JOINER) assuming this role). Nevertheless Unicode software still must be able to handle U+FEFF in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a string; as a ZERO WIDTH NO-BREAK SPACE it's a normal character that will be decoded like any other.

There's another encoding that is able to encode the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four 1 bits followed by a 0 bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

### Encoding

|          |                          |
|----------|--------------------------|
| 0xxxxx   | 0000 ... U-0000007F      |
| 110xxxxx | 10xxxxx-000007FF         |
| 1110xxxx | 10xxxxx-10xxxxFF         |
| 11110xxx | 10xxxxx-10xxxxFF10xxxxxx |

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python calls "utf-8-sig") for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence: 0xef, 0xbb, 0xbf) is written. As it's rather improbable that any charmap encoded file starts with these byte

values (which would e.g. map to

LATIN SMALL LETTER I WITH DIAERESIS  
RIGHT-POINTING DOUBLE ANGLE QUOTATION  
MARK  
INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a `utf-8-sig` encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the `utf-8-sig` codec will write `0xef`, `0xbb`, `0xbf` as the first three bytes to the file. On decoding `utf-8-sig` will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

## Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. `'utf-8'` is a valid alias for the `'utf_8'` codec.

**CPython implementation detail:** Some common encodings can bypass the codecs lookup machinery to improve performance. These optimization opportunities are only recognized by CPython for a limited set of (case insensitive) aliases: `utf-8`, `utf8`, `latin-1`, `latin1`, `iso-8859-1`, `iso8859-1`, `mbcs` (Windows only), `ascii`, `us-ascii`, `utf-16`, `utf16`, `utf-32`, `utf32`, and the same using underscores instead of dashes. Using alternative aliases for these encodings may result in slower execution.

*Changed in version 3.6:* Optimization opportunity recognized for `us-ascii`.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

| <del>utf16utf8</del>           |                                            |
| <del>utf7unicode1-1-utf7</del> |                                            |
| <del>utf8utf16</del>           | utf8, cp65001                              |
| <del>utf8utf8</del>            |                                            |

Changed in version 3.4: The utf-16\* and utf-32\* encoders no longer allow surrogate code points (U+D800–U+DFFF) to be encoded. The

utf-32\* decoders no longer decode byte sequences that correspond to surrogate code points.

*Changed in version 3.8:* cp65001 is now an alias to utf\_8.

## Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated meaning describes the encoding direction.

### Text Encodings

The following codecs provide **str** to **bytes** encoding and **bytes-like object** to **str** decoding, similar to the Unicode text encodings.

#### ~~Encoding~~

---

Implement **RFC 3490**, see also **encodings.idna**. Only errors='strict' is supported.

---

~~Windows only:~~ Encode the operand according to the ANSI codepage (CP\_ACP).

---

~~Windows only:~~ Encode the operand according to the OEM codepage (CP\_OEMCP).

---

*New in version 3.6.*

---

~~Encoding of PalmOS 3.5.~~

---

Implement **RFC 3492**. Stateful codecs are not supported.

---

~~Latin-1 encoding~~ with \uXXXX and \UXXXXXXXX for other code points. Existing backslashes are not escaped in any way. It is used in the Python pickle protocol.

---

~~Raise an exception~~ for all conversions, even empty strings. The error handler is ignored.

---

~~Unicode escape~~ as the contents of a Unicode literal in ASCII-encoded Python source code, except that quotes are not escaped. Decode from Latin-1 source code. Beware that Python source code actually uses UTF-8 by default.

---

Changed in version 3.8: “unicode\_internal” codec is removed.

## Binary Transforms

The following codecs provide binary transforms: `bytes-like object` to `bytes` mappings. They are not supported by `bytes.decode()` (which only produces `str` output).

### ~~Encoding~~ / decoder

---

~~`base64.encodebytes()` and `base64.decodebytes()` (the result always includes a trailing `'\n'`).~~

---

Changed in version 3.4: accepts any `bytes-like object` as input for encoding and decoding

---

~~`base64.urlsafe_b64encode()` and `base64.urlsafe_b64decode()`~~

---

~~For use with the `base64.urlsafe_b64encode()` and `base64.urlsafe_b64decode()`, with two digits per byte.~~

---

~~`quopri.encode()` and `quopri.decode()` (with MIME quoted-printable).~~

---

~~`quopri.encode()` and `quopri.decode()`~~

---

~~Current code operand using `ugettext()`.~~

---

~~`gzip.compress()` and `gzip.decompress()`~~

---

1

In addition to `bytes-like objects`, `'base64_codec'` also accepts ASCII-only instances of `str` for decoding

New in version 3.2: Restoration of the binary transforms.

Changed in version 3.4: Restoration of the aliases for the binary transforms.

## Text Transforms

The following codec provides a text transform: a `str` to `str` mapping. It is not supported by `str.encode()` (which only produces `bytes` output).

### ~~Encoding~~

---

~~`rot13` the Caesar-cypher encryption of the operand.~~

---

New in version 3.2: Restoration of the `rot_13` text transform.

*Changed in version 3.4:* Restoration of the `rot13` alias.

## **encodings.idna** — Internationalized Domain Names in Applications

This module implements **RFC 3490** [<https://datatracker.ietf.org/doc/html/rfc3490.html>] (Internationalized Domain Names in Applications) and **RFC 3492** [<https://datatracker.ietf.org/doc/html/rfc3492.html>] (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and **`stringprep`**.

If you need the IDNA 2008 standard from **RFC 5891** [<https://datatracker.ietf.org/doc/html/rfc5891.html>] and **RFC 5895** [<https://datatracker.ietf.org/doc/html/rfc5895.html>], use the third-party **`idna` module** [<https://pypi.org/project/idna/>].

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in **section 3.1 of RFC 3490** [<https://datatracker.ietf.org/doc/html/rfc3490.html#section-3.1>] and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the **`socket`** module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the `socket` module. On top of that, modules that have host names as

function parameters, such as `http.client` and `ftplib`, accept Unicode host names (`http.client` then also transparently sends an IDNA hostname in the *Host* field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: applications wishing to present such host names to the user should decode them to Unicode.

The module `encodings.idna` also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.nameprep(label)`

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is `true`.

`encodings.idna.ToASCII(label)`

Convert a label to ASCII, as specified in [RFC 3490](https://datatracker.ietf.org/doc/html/rfc3490) [https://datatracker.ietf.org/doc/html/rfc3490.html]. `UseSTD3ASCIIRules` is assumed to be `false`.

`encodings.idna.ToUnicode(label)`

Convert a label to Unicode, as specified in [RFC 3490](https://datatracker.ietf.org/doc/html/rfc3490) [https://datatracker.ietf.org/doc/html/rfc3490.html].

## `encodings.mbcs` — Windows ANSI codepage

This module implements the ANSI codepage (CP\_ACP).

**Availability:** Windows.

*Changed in version 3.3:* Support any error handler.

*Changed in version 3.2:* Before 3.2, the *errors* argument was ignored; 'replace' was always used to encode, and 'ignore' to decode.

## **encodings.utf\_8\_sig** — UTF-8 codec with BOM signature

This module implements a variant of the UTF-8 codec. On encoding, a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). On decoding, an optional UTF-8 encoded BOM at the start of the data will be skipped.

# Data Types

The modules described in this chapter provide a variety of specialized data types such as dates and times, fixed-type arrays, heap queues, double-ended queues, and enumerations.

Python also provides some built-in data types, in particular, `dict`, `list`, `set` and `frozenset`, and `tuple`. The `str` class is used to hold Unicode strings, and the `bytes` and `bytearray` classes are used to hold binary data.

The following modules are documented in this chapter:

- `datetime` — Basic date and time types
  - Aware and Naive Objects
    - Common Properties
    - Determining if an Object is Aware or Naive
  - `timedelta` Objects
    - Examples of usage: `timedelta`
  - `date` Objects
    - Examples of Usage: `date`
  - `datetime` Objects
    - Examples of Usage: `datetime`
  - `time` Objects
    - Examples of Usage: `time`

- **tzinfo** Objects
- **timezone** Objects
- **strptime()** and **strptime()** Behavior
  - **strptime()** and **strptime()** Format Codes
  - Technical Detail
- **zoneinfo** — IANA time zone support
  - Using **ZoneInfo**
  - Data sources
    - Configuring the data sources
      - Compile-time configuration
      - Environment configuration
      - Runtime configuration
  - The **ZoneInfo** class
    - String representations
    - Pickle serialization
  - Functions
  - Globals
  - Exceptions and warnings
- **calendar** — General calendar-related functions
- **collections** — Container datatypes
  - **ChainMap** objects
    - **ChainMap** Examples and Recipes
  - **Counter** objects
  - **deque** objects
    - **deque** Recipes
  - **defaultdict** objects
    - **defaultdict** Examples

- **namedtuple()** Factory Function for Tuples with Named Fields
- **OrderedDict** objects

### ■ **OrderedDict** Examples and Recipes

- **UserDict** objects
- **UserList** objects
- **UserString** objects
- **collections.abc** — Abstract Base Classes for Containers
  - Collections Abstract Base Classes
  - Collections Abstract Base Classes – Detailed Descriptions
  - Examples and Recipes
- **heapq** — Heap queue algorithm
  - Basic Examples
  - Priority Queue Implementation Notes
  - Theory
- **bisect** — Array bisection algorithm
  - Performance Notes
  - Searching Sorted Lists
  - Examples
- **array** — Efficient arrays of numeric values
- **weakref** — Weak references
  - Weak Reference Objects
  - Example
  - Finalizer Objects
  - Comparing finalizers with **\_\_del\_\_()** methods
- **types** — Dynamic type creation and names for built-in types
  - Dynamic Type Creation
  - Standard Interpreter Types
  - Additional Utility Classes and Functions

- Coroutine Utility Functions
- **copy** — Shallow and deep copy operations
- **pprint** — Data pretty printer
  - PrettyPrinter Objects
  - Example
- **reprlib** — Alternate **repr()** implementation
  - Repr Objects
  - Subclassing Repr Objects
- **enum** — Support for enumerations
  - Module Contents
  - Data Types
    - Supported **\_\_dunder\_\_** names
    - Supported **\_sunder\_** names
  - Utilities and Decorators
  - Notes
- **graphlib** — Functionality to operate with graph-like structures
  - Exceptions

# `datetime` — Basic date and time types

**Source code:** [Lib/datetime.py](https://github.com/python/cpython/tree/3.11/Lib/datetime.py) [https://github.com/python/cpython/tree/3.11/Lib/datetime.py]

---

The `datetime` module supplies classes for manipulating dates and times.

While date and time arithmetic is supported, the focus of the implementation is on efficient attribute extraction for output formatting and manipulation.

**See also**

**Module** `calendar`

General calendar related functions.

**Module** `time`

Time access and conversions.

**Module** `zoneinfo`

Concrete time zones representing the IANA time zone database.

**Package** `dateutil` [https://dateutil.readthedocs.io/en/stable/]

Third-party library with expanded time zone and parsing support.

## Aware and Naive Objects

Date and time objects may be categorized as “aware” or “naive” depending on whether or not they include timezone information.

With sufficient knowledge of applicable algorithmic and political time adjustments, such as time zone and daylight saving time information, an **aware** object can locate itself relative to other aware objects. An aware object represents a specific moment in time that is not open to interpretation. 1

A **naive** object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other timezone is purely up to the program, just like it is up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, `datetime` and `time` objects have an optional time zone information attribute, `tzinfo`, that can be set to an instance of a subclass of the abstract `tzinfo` class. These `tzinfo` objects capture information about the offset from UTC time, the time zone name, and whether daylight saving time is in effect.

Only one concrete `tzinfo` class, the `timezone` class, is supplied by the `datetime` module. The `timezone` class can represent simple timezones with fixed offsets from UTC, such as UTC itself or North American EST and EDT timezones. Supporting timezones at deeper levels of detail is up to the application. The rules for time adjustment across the world are more political than rational, change frequently, and there is no standard suitable for every application aside from UTC.

## Constants

The `datetime` module exports the following constants:

`datetime.MINYEAR`

The smallest year number allowed in a `date` or `datetime` object. `MINYEAR` is 1.

`datetime.MAXYEAR`

The largest year number allowed in a `date` or `datetime` object. `MAXYEAR` is 9999.

`datetime.UTC`

Alias for the UTC timezone singleton  
`datetime.timezone.utc`.

*New in version 3.11.*

## Available Types

*class* `datetime.date`

An idealized naive date, assuming the current Gregorian calendar always was, and always will be, in effect. Attributes: `year`, `month`, and `day`.

*class* `datetime.time`

An idealized time, independent of any particular day, assuming that every day has exactly 24\*60\*60 seconds. (There is no notion of “leap seconds” here.) Attributes: `hour`, `minute`, `second`, `microsecond`, and `tzinfo`.

*class* `datetime.datetime`

A combination of a date and a time. Attributes: `year`, `month`, `day`, `hour`, `minute`, `second`, `microsecond`, and `tzinfo`.

*class* `datetime.timedelta`

A duration expressing the difference between two `date`, `time`, or `datetime` instances to microsecond resolution.

*class* `datetime.tzinfo`

An abstract base class for time zone information objects. These are used by the `datetime` and `time` classes to provide a customizable notion of time adjustment (for example, to account for time zone and/or daylight saving time).

*class* `datetime.timezone`

A class that implements the `tzinfo` abstract base class as a fixed offset from the UTC.

*New in version 3.2.*

Objects of these types are immutable.

Subclass relationships:

```
object
  timedelta
  tzinfo
    timezone
  time
  date
    datetime
```

## Common Properties

The `date`, `datetime`, `time`, and `timezone` types share these common features:

- Objects of these types are immutable.
- Objects of these types are `hashable`, meaning that they can be used as dictionary keys.
- Objects of these types support efficient pickling via the `pickle` module.

## Determining if an Object is Aware or Naive

Objects of the `date` type are always naive.

An object of type `time` or `datetime` may be aware or naive.

A `datetime` object *d* is aware if both of the following hold:

1. `d.tzinfo` is not `None`
2. `d.tzinfo.utcoffset(d)` does not return `None`

Otherwise, *d* is naive.

A **time** object *t* is aware if both of the following hold:

1. `t.tzinfo` is not `None`
2. `t.tzinfo.utcoffset(None)` does not return `None`.

Otherwise, *t* is naive.

The distinction between aware and naive doesn't apply to **timedelta** objects.

## **timedelta** Objects

A **timedelta** object represents a duration, the difference between two dates or times.

```
class datetime.timedelta(days=0, seconds=0, microseconds=0,  
milliseconds=0, minutes=0, hours=0, weeks=0)
```

All arguments are optional and default to 0. Arguments may be integers or floats, and may be positive or negative.

Only *days*, *seconds* and *microseconds* are stored internally. Arguments are converted to those units:

- A millisecond is converted to 1000 microseconds.
- A minute is converted to 60 seconds.
- An hour is converted to 3600 seconds.
- A week is converted to 7 days.

and days, seconds and microseconds are then normalized so that the representation is unique, with

- `0 <= microseconds < 1000000`
- `0 <= seconds < 3600*24` (the number of seconds in one day)
- `-999999999 <= days <= 999999999`

The following example illustrates how any arguments besides *days*, *seconds* and *microseconds* are “merged” and normalized into those three resulting attributes:

```
>>> from datetime import timedelta
>>> delta = timedelta(
...     days=50,
...     seconds=27,
...     microseconds=10,
...     milliseconds=29000,
...     minutes=5,
...     hours=8,
...     weeks=2
... )
>>> # Only days, seconds, and microseconds remain
>>> delta
datetime.timedelta(days=64, seconds=29156, microsec
```

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond using round-half-to-even tiebreaker. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

If the normalized value of days lies outside the indicated range, **OverflowError** is raised.

Note that normalization of negative values may be surprising at first. For example:

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

Class attributes:

`timedelta.min`

The most negative **timedelta** object,  
`timedelta(-999999999)`.

`timedelta.max`

The most positive `timedelta` object,  
`timedelta(days=999999999, hours=23,  
minutes=59, seconds=59, microseconds=999999)`.

`timedelta.resolution`

The smallest possible difference between non-equal  
`timedelta` objects, `timedelta(microseconds=1)`.

Note that, because of normalization, `timedelta.max > -timedelta.min`. `-timedelta.max` is not representable as a `timedelta` object.

Instance attributes (read-only):

#### Attribute

---

Between -999999999 and 999999999 inclusive

---

Between 0 and 86399 inclusive

---

Between 0 and 999999 inclusive

---

Supported operations:

#### Operation

---

Sum of  $t_2$  and  $t_3$ . Afterwards  $t_1 - t_2 == t_3$  and  $t_1 - t_3 == t_2$  are true. (1)

---

Difference of  $t_2$  and  $t_3$ . Afterwards  $t_1 == t_2 - t_3$  and  $t_2 == t_1 + t_3$  are true. (1)(6)

---

Delta multiplied by an integer: Afterwards  $t_1 // i == t_2$  is true, provided  $i \neq 0$ .

---

In general,  $t_1 * i == t_1 * (i-1) + t_1$  is true. (1)

---

Delta multiplied by a float. The result is rounded to the nearest multiple of `timedelta.resolution` using round-half-to-even.

---

Division (3) of overall duration  $t_2$  by interval unit  $t_3$ . Returns a `float` object.

---

Delta divided by a float or an int. The result is rounded to the nearest multiple of `timedelta.resolution` using round-half-to-even.

---

The floor is computed and the remainder (if any) is thrown away.

---

In the second case, an integer is returned. (3)

---

The remainder is computed as a `timedelta` object. (3)

---

Computes the quotient and the remainder:  $q = t_1 // t_2$  (3) and  $r = t_1 \% t_2$ .  $q$  is an integer and  $r$  is a `timedelta`

---

object.

---

Returns a `timedelta` object with the same value. (2)

---

equivalent to `timedelta(-t1.days, -t1.seconds, -t1.microseconds)`, and to  $t1^* -1$ . (1)(4)

---

equivalent to  $+t$  when `t.days >= 0`, and to  $-t$  when `t.days < 0`. (2)

---

Returns a string in the form `[D day[s], ]`

---

`[H]H:MM:SS[.UUUUUU]`, where `D` is negative for negative `t`. (5)

---

Returns a string representation of the `timedelta` object as a constructor call with canonical attribute values.

---

Notes:

1. This is exact but may overflow.
2. This is exact and cannot overflow.
3. Division by 0 raises `ZeroDivisionError`.
4. `-timedelta.max` is not representable as a `timedelta` object.
5. String representations of `timedelta` objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:  

```
>>> timedelta(hours=-5)
datetime.timedelta(days=-1, seconds=68400)
>>> print(_)
-1 day, 19:00:00
```
6. The expression `t2 - t3` will always be equal to the expression `t2 + (-t3)` except when `t3` is equal to `timedelta.max`; in that case the former will produce a result while the latter will overflow.

In addition to the operations listed above, `timedelta` objects support certain additions and subtractions with `date` and `datetime` objects (see below).

*Changed in version 3.2:* Floor division and true division of a `timedelta` object by another `timedelta` object are now supported, as are remainder operations and the `divmod()` function. True division and multiplication of a `timedelta` object by a `float` object are now supported.

Comparisons of `timedelta` objects are supported, with some caveats.

The comparisons `==` or `!=` *always* return a `bool`, no matter the type of the compared object:

```
>>> from datetime import timedelta
>>> delta1 = timedelta(seconds=57)
>>> delta2 = timedelta(hours=25, seconds=2)
>>> delta2 != delta1
True
>>> delta2 == 5
False
```

For all other comparisons (such as `<` and `>`), when a `timedelta` object is compared to an object of a different type, `TypeError` is raised:

```
>>> delta2 > delta1
True
>>> delta2 > 5
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '>' not supported between instances of 'datetime.timedelta' and 'int'
```

In Boolean contexts, a `timedelta` object is considered to be true if and only if it isn't equal to `timedelta(0)`.

Instance methods:

`timedelta.total_seconds()`

Return the total number of seconds contained in the duration. Equivalent to `td / timedelta(seconds=1)`. For interval units other than seconds, use the division form directly (e.g.

```
td / timedelta(microseconds=1)).
```

Note that for very large time intervals (greater than 270 years on most platforms) this method will lose microsecond accuracy.

*New in version 3.2.*

## Examples of usage: `timedelta`

An additional example of normalization:

```
>>> # Components of another_year add up to exactly 365 d
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23
...                           minutes=50, seconds=600)
>>> year == another_year
True
>>> year.total_seconds()
31536000.0
```

Examples of `timedelta` arithmetic:

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> ten_years = 10 * year
>>> ten_years
datetime.timedelta(days=3650)
>>> ten_years.days // 365
10
>>> nine_years = ten_years - year
>>> nine_years
datetime.timedelta(days=3285)
>>> three_years = nine_years // 3
>>> three_years, three_years.days // 365
(datetime.timedelta(days=1095), 3)
```

## `date` Objects

A `date` object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions.

January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on. 2

*class* `datetime.date(year, month, day)`

All arguments are required. Arguments must be integers, in the following ranges:

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`

If an argument outside those ranges is given, `ValueError` is raised.

Other constructors, all class methods:

*classmethod* `date.today()`

Return the current local date.

This is equivalent to

`date.fromtimestamp(time.time())`.

*classmethod* `date.fromtimestamp(timestamp)`

Return the local date corresponding to the POSIX timestamp, such as is returned by `time.time()`.

This may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C

`localtime()` function, and `OSError` on `localtime()` failure. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`.

*Changed in version 3.3:* Raise `OverflowError` instead of

**ValueError** if the timestamp is out of the range of values supported by the platform C `localtime()` function. Raise **OSError** instead of **ValueError** on `localtime()` failure.

*classmethod* `date.fromordinal(ordinal)`

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1.

**ValueError** is raised unless `1 <= ordinal <= date.max.toordinal()`. For any date *d*,  
`date.fromordinal(d.toordinal()) == d`.

*classmethod* `date.fromisoformat(date_string)`

Return a **date** corresponding to a *date\_string* given in any valid ISO 8601 format, except ordinal dates (e.g. YYYY-DDD):

```
>>> from datetime import date
>>> date.fromisoformat('2019-12-04')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('20191204')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('2021-W01-1')
datetime.date(2021, 1, 4)
```

*New in version 3.7.*

*Changed in version 3.11:* Previously, this method only supported the format YYYY-MM-DD.

*classmethod* `date.fromisocalendar(year, week, day)`

Return a **date** corresponding to the ISO calendar date specified by year, week and day. This is the inverse of the function `date.isocalendar()`.

*New in version 3.8.*

Class attributes:

date.min

The earliest representable date, `date(MINYEAR, 1, 1)`.

date.max

The latest representable date, `date(MAXYEAR, 12, 31)`.

date.resolution

The smallest possible difference between non-equal date objects, `timedelta(days=1)`.

Instance attributes (read-only):

date.year

Between **MINYEAR** and **MAXYEAR** inclusive.

date.month

Between 1 and 12 inclusive.

date.day

Between 1 and the number of days in the given month of the given year.

Supported operations:

### **Definition**

---

*date2* will be `timedelta(days)` days after *date1*. (1)

---

Computes *date2* such that `date2 + timedelta == date1`.

---

(2)

---

(3) `timedelta = date1 - date2`

---

*date1* is considered less than *date2* when *date1* precedes *date2* in time. (4)

---

Notes:

1. *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days * timedelta.seconds` and `timedelta.microseconds` are ignored.

**OverflowError** is raised if `date2.year` would be smaller than **MINYEAR** or larger than **MAXYEAR**.

2. `timedelta.seconds` and `timedelta.microseconds` are ignored.
3. This is exact, and cannot overflow. `timedelta.seconds` and `timedelta.microseconds` are 0, and `date2 + timedelta == date1` after.
4. In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`. Date comparison raises **TypeError** if the other comparand isn't also a **date** object. However, **NotImplemented** is returned instead if the other comparand has a **timetuple()** attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a **date** object is compared to an object of a different type, **TypeError** is raised unless the comparison is `==` or `!=`. The latter cases return **False** or **True**, respectively.

In Boolean contexts, all **date** objects are considered to be true.

Instance methods:

`date.replace(year=self.year, month=self.month, day=self.day)`

Return a date with the same value, except for those parameters given new values by whichever keyword arguments are specified.

Example:

```
>>> from datetime import date
>>> d = date(2002, 12, 31)
>>> d.replace(day=26)
datetime.date(2002, 12, 26)
```

`date.timetuple()`

Return a **time.struct\_time** such as returned by **time.localtime()**.

The hours, minutes and seconds are 0, and the DST flag is -1.

`d.timetuple()` is equivalent to:

```
time.struct_time((d.year, d.month, d.day, 0, 0, 0,
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

### `date.toordinal()`

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any `date` object `d`, `date.fromordinal(d.toordinal()) == d`.

### `date.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. For example, `date(2002, 12, 4).weekday() == 2`, a Wednesday. See also `isoweekday()`.

### `date.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. For example, `date(2002, 12, 4).isoweekday() == 3`, a Wednesday. See also `weekday()`, `isocalendar()`.

### `date.isocalendar()`

Return a `named tuple` object with three components: `year`, `week` and `weekday`.

The ISO calendar is a widely used variant of the Gregorian calendar. 3

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004:

```
>>> from datetime import date
>>> date(2003, 12, 29).isocalendar()
datetime.ISOCalendarDate(year=2004, week=1, weekday
>>> date(2004, 1, 4).isocalendar()
datetime.ISOCalendarDate(year=2004, week=1, weekday
```

*Changed in version 3.9:* Result changed from a tuple to a [named tuple](#).

### `date.isoformat()`

Return a string representing the date in ISO 8601 format, YYYY-MM-DD:

```
>>> from datetime import date
>>> date(2002, 12, 4).isoformat()
'2002-12-04'
```

### `date.__str__()`

For a date *d*, `str(d)` is equivalent to `d.isoformat()`.

### `date.ctime()`

Return a string representing the date:

```
>>> from datetime import date
>>> date(2002, 12, 4).ctime()
'Wed Dec  4 00:00:00 2002'
```

`d.ctime()` is equivalent to:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which [time.ctime\(\)](#) invokes, but which [date.ctime\(\)](#) does not invoke) conforms to the C standard.

`date.strftime(format)`

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. See also [strftime\(\) and strptime\(\) Behavior](#) and [date.isoformat\(\)](#).

`date._format_(format)`

Same as [date.strftime\(\)](#). This makes it possible to specify a format string for a [date](#) object in [formatted string literals](#) and when using [str.format\(\)](#). See also [strftime\(\) and strptime\(\) Behavior](#) and [date.isoformat\(\)](#).

## Examples of Usage: [date](#)

Example of counting days to an event:

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year)
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

More examples of working with [date](#):

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1.
>>> d
datetime.date(2002, 3, 11)
```

```

>>> # Methods related to formatting string output
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> d.ctime()
'Mon Mar 11 00:00:00 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "c")
'The day is 11, the month is March.'

>>> # Methods for to extracting 'components' under different
>>> t = d.timetuple()
>>> for i in t:
...     print(i)
2002                # year
3                   # month
11                  # day
0
0
0
0                   # weekday (0 = Monday)
70                  # 70th day in the year
-1

>>> ic = d.isocalendar()
>>> for i in ic:
...     print(i)
2002                # ISO year
11                  # ISO week number
1                   # ISO day number ( 1 = Monday )

>>> # A date object is immutable; all operations produce new objects
>>> d.replace(year=2005)
datetime.date(2005, 3, 11)

```

## datetime Objects

A `datetime` object is a single object containing all the information from a `date` object and a `time` object.

Like a `date` object, `datetime` assumes the current Gregorian calendar extended in both directions; like a `time` object, `datetime` assumes there are exactly  $3600 \times 24$  seconds in every day.

Constructor:

```
class datetime.datetime(year, month, day, hour=0, minute=0,
second=0, microsecond=0, tzinfo=None, *, fold=0)
```

The *year*, *month* and *day* arguments are required. *tzinfo* may be `None`, or an instance of a `tzinfo` subclass. The remaining arguments must be integers in the following ranges:

- `MINYEAR <= year <= MAXYEAR`,
- `1 <= month <= 12`,
- `1 <= day <= number of days in the given month and year`,
- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold` in `[0, 1]`.

If an argument outside those ranges is given, `ValueError` is raised.

*New in version 3.6:* Added the `fold` argument.

Other constructors, all class methods:

```
classmethod datetime.today()
```

Return the current local datetime, with `tzinfo` `None`.

Equivalent to:

```
datetime.fromtimestamp(time.time())
```

See also `now()`, `fromtimestamp()`.

This method is functionally equivalent to `now()`, but without a `tz` parameter.

*classmethod* `datetime.now(tz=None)`

Return the current local date and time.

If optional argument `tz` is `None` or not specified, this is like `today()`, but, if possible, supplies more precision than can be gotten from going through a `time.time()` timestamp (for example, this may be possible on platforms supplying the C `gettimeofday()` function).

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the current date and time are converted to `tz`'s time zone.

This function is preferred over `today()` and `utcnow()`.

*classmethod* `datetime.utcnow()`

Return the current UTC date and time, with `tzinfo` `None`.

This is like `now()`, but returns the current UTC date and time, as a naive `datetime` object. An aware current UTC datetime can be obtained by calling `datetime.now(timezone.utc)`. See also `now()`.

## Warning

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing the current time in UTC is by calling `datetime.now(timezone.utc)`.

*classmethod* `datetime.fromtimestamp(timestamp, tz=None)`

Return the local date and time corresponding to the POSIX timestamp, such as is returned by `time.time()`. If optional argument `tz` is `None` or not specified, the timestamp is converted to the platform's local date and time, and the returned `datetime` object is naive.

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the timestamp is converted to `tz`'s time zone.

`fromtimestamp()` may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions, and `OSError` on `localtime()` or `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`, and then it's possible to have two timestamps differing by a second that yield identical `datetime` objects. This method is preferred over `utcfromtimestamp()`.

*Changed in version 3.3:* Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. Raise `OSError` instead of `ValueError` on `localtime()` or `gmtime()` failure.

*Changed in version 3.6:* `fromtimestamp()` may return instances with `fold` set to 1.

*classmethod* `datetime.utcfromtimestamp(timestamp)`

Return the UTC `datetime` corresponding to the POSIX timestamp, with `tzinfo` `None`. (The resulting object is naive.)

This may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `gmtime()` function, and `OSError` on `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038.

To get an aware `datetime` object, call `fromtimestamp()`:

```
datetime.fromtimestamp(timestamp, timezone.utc)
```

On the POSIX compliant platforms, it is equivalent to the following expression:

```
datetime(1970, 1, 1, tzinfo=timezone.utc) + timedelta
```

except the latter formula always supports the full years range: between `MINYEAR` and `MAXYEAR` inclusive.

### Warning

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing a specific timestamp in UTC is by calling

```
datetime.fromtimestamp(timestamp,  
tz=timezone.utc).
```

*Changed in version 3.3:* Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `gmtime()` function. Raise `OSError` instead of `ValueError` on `gmtime()` failure.

*classmethod* `datetime.fromordinal(ordinal)`

Return the `datetime` corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. `ValueError` is raised unless `1 <= ordinal <= datetime.max.toordinal()`. The hour, minute, second and microsecond of the result are all 0, and `tzinfo` is `None`.

*classmethod* `datetime.combine(date, time, tzinfo=self.tzinfo)`

Return a new `datetime` object whose date components are equal to the given `date` object's, and whose time components are equal to the given `time` object's. If the `tzinfo`

argument is provided, its value is used to set the `tzinfo` attribute of the result, otherwise the `tzinfo` attribute of the `time` argument is used.

For any `datetime` object `d`, `d == datetime.combine(d.date(), d.time(), d.tzinfo)`. If `date` is a `datetime` object, its time components and `tzinfo` attributes are ignored.

*Changed in version 3.6:* Added the `tzinfo` argument.

*classmethod* `datetime.fromisoformat(date_string)`

Return a `datetime` corresponding to a `date_string` in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The `T` separator may be replaced by any single unicode character.
3. Ordinal dates are not currently supported.
4. Fractional hours and minutes are not supported.

Examples:

```
>>> from datetime import datetime
>>> datetime.fromisoformat('2011-11-04')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('20111104')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('2011-11-04T00:05:23')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-11-04T00:05:23Z')
datetime.datetime(2011, 11, 4, 0, 5, 23, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('20111104T000523')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-W01-2T00:05:23.283')
datetime.datetime(2011, 1, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000, tzinfo=datetime.timezone.utc)
```

```
>>> datetime.fromisoformat('2011-11-04T00:05:23+04:00')
datetime.datetime(2011, 11, 4, 0, 5, 23, tzinfo=datetime.timezone(datetime.timedelta(seconds=14400)))
```

*New in version 3.7.*

*Changed in version 3.11:* Previously, this method only supported formats that could be emitted by `date.isoformat()` or `datetime.isoformat()`.

*classmethod* `datetime.fromisocalendar(year, week, day)`

Return a `datetime` corresponding to the ISO calendar date specified by year, week and day. The non-date components of the datetime are populated with their normal default values. This is the inverse of the function `datetime.isocalendar()`.

*New in version 3.8.*

*classmethod* `datetime.strptime(date_string, format)`

Return a `datetime` corresponding to `date_string`, parsed according to `format`.

If `format` does not contain microseconds or timezone information, this is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

`ValueError` is raised if the `date_string` and `format` can't be parsed by `time.strptime()` or if it returns a value which isn't a time tuple. See also `strptime()` Behavior and `datetime.fromisoformat()`.

Class attributes:

`datetime.min`

The earliest representable `datetime`,  
`datetime(MINYEAR, 1, 1, tzinfo=None)`.

`datetime.max`

The latest representable `datetime`, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

`datetime.resolution`

The smallest possible difference between non-equal `datetime` objects, `timedelta(microseconds=1)`.

Instance attributes (read-only):

`datetime.year`

Between `MINYEAR` and `MAXYEAR` inclusive.

`datetime.month`

Between 1 and 12 inclusive.

`datetime.day`

Between 1 and the number of days in the given month of the given year.

`datetime.hour`

In `range(24)`.

`datetime.minute`

In `range(60)`.

`datetime.second`

In `range(60)`.

`datetime.microsecond`

In `range(1000000)`.

`datetime.tzinfo`

The object passed as the `tzinfo` argument to the `datetime` constructor, or `None` if none was passed.

datetime.fold

In [0, 1]. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The value 0 (1) represents the earlier (later) of the two moments with the same wall time representation.

*New in version 3.6.*

Supported operations:

**Operation**

(1) datetime2 = datetime1 + timedelta

(2) datetime2 = datetime1 - timedelta

(3) timedelta = datetime1 - datetime2

Compares datetime1 to datetime2. (4)

1. datetime2 is a duration of timedelta removed from datetime1, moving forward in time if timedelta.days > 0, or backward if timedelta.days < 0. The result has the same tzinfo attribute as the input datetime, and datetime2 - datetime1 == timedelta after. OverflowError is raised if datetime2.year would be smaller than MINYEAR or larger than MAXYEAR. Note that no time zone adjustments are done even if the input is an aware object.
2. Computes the datetime2 such that datetime2 + timedelta == datetime1. As for addition, the result has the same tzinfo attribute as the input datetime, and no time zone adjustments are done even if the input is aware.
3. Subtraction of a datetime from a datetime is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, TypeError is raised.

If both are naive, or both are aware and have the same tzinfo attribute, the tzinfo attributes are ignored, and the result is a timedelta object t such that datetime2 + t == datetime1. No time zone adjustments are done in this case.

If both are aware and have different `tzinfo` attributes, `a-b` acts as if `a` and `b` were first converted to naive UTC datetimes first. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

4. *datetime1* is considered less than *datetime2* when *datetime1* precedes *datetime2* in time.

If one comparand is naive and the other is aware, `TypeError` is raised if an order comparison is attempted. For equality comparisons, naive instances are never equal to aware instances.

If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base datetimes are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

*Changed in version 3.3:* Equality comparisons between aware and naive `datetime` instances don't raise `TypeError`.

## Note

In order to stop comparison from falling back to the default scheme of comparing object addresses, `datetime` comparison normally raises `TypeError` if the other comparand isn't also a `datetime` object. However, `NotImplemented` is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a `datetime` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

Instance methods:

`datetime.date()`

Return **date** object with same year, month and day.

`datetime.time()`

Return **time** object with same hour, minute, second, microsecond and fold. **tzinfo** is `None`. See also method **timetz()**.

*Changed in version 3.6:* The fold value is copied to the returned **time** object.

`datetime.timetz()`

Return **time** object with same hour, minute, second, microsecond, fold, and tzinfo attributes. See also method **time()**.

*Changed in version 3.6:* The fold value is copied to the returned **time** object.

`datetime.replace(year=self.year, month=self.month, day=self.day, hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *, fold=0)`

Return a datetime with the same attributes, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive datetime from an aware datetime with no conversion of date and time data.

*New in version 3.6:* Added the `fold` argument.

`datetime.astimezone(tz=None)`

Return a **datetime** object with new **tzinfo** attribute `tz`, adjusting the date and time data so the result is the same UTC time as `self`, but in `tz`'s local time.

If provided, `tz` must be an instance of a **tzinfo** subclass, and

its `utcoffset()` and `dst()` methods must not return `None`. If *self* is naive, it is presumed to represent time in the system timezone.

If called without arguments (or with `tz=None`) the system local timezone is assumed for the target timezone. The `.tzinfo` attribute of the converted datetime instance will be set to an instance of `timezone` with the zone name and offset obtained from the OS.

If `self.tzinfo` is *tz*, `self.astimezone(tz)` is equal to *self*: no adjustment of date or time data is performed. Else the result is local time in the timezone *tz*, representing the same UTC time as *self*: after `astz = dt.astimezone(tz)`, `astz - astz.utcoffset()` will have the same date and time data as `dt - dt.utcoffset()`.

If you merely want to attach a time zone object *tz* to a datetime *dt* without adjustment of date and time data, use `dt.replace(tzinfo=tz)`. If you merely want to remove the time zone object from an aware datetime *dt* without conversion of date and time data, use `dt.replace(tzinfo=None)`.

Note that the default `tzinfo.fromutc()` method can be overridden in a `tzinfo` subclass to affect the result returned by `astimezone()`. Ignoring error cases, `astimezone()` acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new time
    utc = (self - self.utcoffset()).replace(tzinfo=
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

*Changed in version 3.3:* *tz* now can be omitted.

*Changed in version 3.6:* The `astimezone()` method can now be called on naive instances that are presumed to represent

system local time.

### `datetime.utcoffset()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(self)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

*Changed in version 3.7:* The UTC offset is not restricted to a whole number of minutes.

### `datetime.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(self)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

*Changed in version 3.7:* The DST offset is not restricted to a whole number of minutes.

### `datetime.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(self)`, raises an exception if the latter doesn't return `None` or a string object,

### `datetime.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`.

`d.timetuple()` is equivalent to:

```
time.struct_time((d.year, d.month, d.day,
                  d.hour, d.minute, d.second,
                  d.weekday(), yday, dst))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st. The `tm_isdst` flag of

the result is set according to the `dst()` method: `tzinfo` is `None` or `dst()` returns `None`, `tm_isdst` is set to `-1`; else if `dst()` returns a non-zero value, `tm_isdst` is set to `1`; else `tm_isdst` is set to `0`.

### `datetime.utctimetuple()`

If `datetime` instance `d` is naive, this is the same as `d.timetuple()` except that `tm_isdst` is forced to `0` regardless of what `d.dst()` returns. DST is never in effect for a UTC time.

If `d` is aware, `d` is normalized to UTC time, by subtracting `d.utcoffset()`, and a `time.struct_time` for the normalized time is returned. `tm_isdst` is forced to `0`. Note that an `OverflowError` may be raised if `d.year` was `MINYEAR` or `MAXYEAR` and UTC adjustment spills over a year boundary.

### Warning

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC; as a result, using `datetime.utctimetuple()` may give misleading results. If you have a naive `datetime` representing UTC, use `datetime.replace(tzinfo=timezone.utc)` to make it aware, at which point you can use `datetime.timetuple()`.

### `datetime.toordinal()`

Return the proleptic Gregorian ordinal of the date. The same as `self.date().toordinal()`.

### `datetime.timestamp()`

Return POSIX timestamp corresponding to the `datetime` instance. The return value is a `float` similar to that returned by `time.time()`.

Naive `datetime` instances are assumed to represent local time and this method relies on the platform C `mktime()` function to perform the conversion. Since `datetime` supports wider range of values than `mktime()` on many platforms, this method may raise `OverflowError` for times far in the past or far in the future.

For aware `datetime` instances, the return value is computed as:

```
(dt - datetime(1970, 1, 1, tzinfo=timezone.utc)).to
```

*New in version 3.3.*

*Changed in version 3.6:* The `timestamp()` method uses the `fold` attribute to disambiguate the times during a repeated interval.

### Note

There is no method to obtain the POSIX timestamp directly from a naive `datetime` instance representing UTC time. If your application uses this convention and your system timezone is not set to UTC, you can obtain the POSIX timestamp by supplying `tzinfo=timezone.utc`:

```
timestamp = dt.replace(tzinfo=timezone.utc).timestamp
```

or by calculating the timestamp directly:

```
timestamp = (dt - datetime(1970, 1, 1)) / timedelt
```

### `datetime.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also `isoweekday()`.

### `datetime.isoweekday()`

Return the day of the week as an integer, where Monday is 1

and Sunday is 7. The same as  
`self.date().isoweekday()`. See also `weekday()`,  
`isocalendar()`.

### `datetime.isocalendar()`

Return a **named tuple** with three components: `year`, `week`  
and `weekday`. The same as  
`self.date().isocalendar()`.

### `datetime.isoformat(sep='T', timespec='auto')`

Return a string representing the date and time in ISO 8601  
format:

- `YYYY-MM-DDTHH:MM:SS.ffffff`, if **microsecond** is not 0
- `YYYY-MM-DDTHH:MM:SS`, if **microsecond** is 0

If `utcoffset()` does not return `None`, a string is  
appended, giving the UTC offset:

- `YYYY-MM-DDTHH:MM:SS.ffffff`  
`+HH:MM[:SS[.ffffff]]`, if **microsecond** is not 0
- `YYYY-MM-DDTHH:MM:SS+HH:MM[:SS[.ffffff]]`, if  
**microsecond** is 0

Examples:

```
>>> from datetime import datetime, timezone
>>> datetime(2019, 5, 18, 15, 17, 8, 132263).isoformat()
'2019-05-18T15:17:08.132263'
>>> datetime(2019, 5, 18, 15, 17, tzinfo=timezone.utc).isoformat()
'2019-05-18T15:17:00+00:00'
```

The optional argument `sep` (default `'T'`) is a one-character  
separator, placed between the date and time portions of the  
result. For example:

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     """A time zone with an arbitrary, constant
```

```
...     def utcoffset(self, dt):
...         return timedelta(hours=-6, minutes=-39)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat('
'2002-12-25 00:00:00-06:39'
>>> datetime(2009, 11, 27, microsecond=100, tzinfo=
'2009-11-27T00:00:00.000100-06:39'
```

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if **microsecond** is 0, same as 'microseconds' otherwise.
- 'hours': Include the **hour** in the two-digit HH format.
- 'minutes': Include **hour** and **minute** in HH:MM format.
- 'seconds': Include **hour**, **minute**, and **second** in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.ffffff format.

## Note

Excluded time components are truncated, not rounded.

**ValueError** will be raised on an invalid *timespec* argument:

```
>>> from datetime import datetime
>>> datetime.now().isoformat(timespec='minutes')
'2002-12-25T00:00'
>>> dt = datetime(2015, 1, 1, 12, 30, 59, 0)
>>> dt.isoformat(timespec='microseconds')
'2015-01-01T12:30:59.000000'
```

*New in version 3.6:* Added the *timespec* argument.

## `datetime._str_()`

For a `datetime` instance `d`, `str(d)` is equivalent to `d.isoformat(' ')`.

## `datetime.ctime()`

Return a string representing the date and time:

```
>>> from datetime import datetime
>>> datetime(2002, 12, 4, 20, 30, 40).ctime()
'Wed Dec  4 20:30:40 2002'
```

The output string will *not* include time zone information, regardless of whether the input is aware or naive.

`d.ctime()` is equivalent to:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `datetime.ctime()` does not invoke) conforms to the C standard.

## `datetime.strftime(format)`

Return a string representing the date and time, controlled by an explicit format string. See also `strftime()` and `strftime() Behavior` and `datetime.isoformat()`.

## `datetime._format_(format)`

Same as `datetime.strftime()`. This makes it possible to specify a format string for a `datetime` object in [formatted string literals](#) and when using `str.format()`. See also `strftime()` and `strftime() Behavior` and `datetime.isoformat()`.

## Examples of Usage: `datetime`

Examples of working with `datetime` objects:

```

>>> from datetime import datetime, date, time, timezone

>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)

>>> # Using datetime.now()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043)    # GMT
>>> datetime.now(timezone.utc)
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060, tzinfo=timezone.utc)

>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)

>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print(it)
...
2006      # year
11        # month
21        # day
16        # hour
30        # minute
0         # second
1         # weekday (0 = Monday)
325       # number of days since 1st January
-1        # dst - method tzinfo.dst() returned None

>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print(it)

```

```

...
2006      # ISO year
47         # ISO week
2          # ISO weekday

>>> # Formatting a datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}'
'The day is 21, the month is November, the time is 04:30PM'

```

The example below defines a `tzinfo` subclass capturing time zone information for Kabul, Afghanistan, which used +4 UTC until 1945 and then +4:30 UTC thereafter:

```

from datetime import timedelta, datetime, tzinfo, timezone

class KabulTz(tzinfo):
    # Kabul used +4 until 1945, when they moved to +4:30
    UTC_MOVE_DATE = datetime(1944, 12, 31, 20, tzinfo=timezone.utc)

    def utcoffset(self, dt):
        if dt.year < 1945:
            return timedelta(hours=4)
        elif (1945, 1, 1, 0, 0) <= dt.timetuple()[5] < (1945, 1, 1, 0, 0) + timedelta(hours=1):
            # An ambiguous ("imaginary") half-hour range
            # a 'fold' in time due to the shift from +4 to +4:30
            # If dt falls in the imaginary range, use fold
            # to resolve. See PEP495.
            return timedelta(hours=4, minutes=(30 if dt.fold else 0))
        else:
            return timedelta(hours=4, minutes=30)

    def fromutc(self, dt):
        # Follow same validations as in datetime.tzinfo
        if not isinstance(dt, datetime):
            raise TypeError("fromutc() requires a datetime")
        if dt.tzinfo is not self:
            raise ValueError("dt.tzinfo is not self")

```

```

        # A custom implementation is required for fromut
        # the input to this function is a datetime with
        # but with a tzinfo set to self.
        # See datetime.astimezone or fromtimestamp.
        if dt.replace(tzinfo=timezone.utc) >= self.UTC_M
            return dt + timedelta(hours=4, minutes=30)
        else:
            return dt + timedelta(hours=4)

    def dst(self, dt):
        # Kabul does not observe daylight saving time.
        return timedelta(0)

    def tzname(self, dt):
        if dt >= self.UTC_MOVE_DATE:
            return "+04:30"
        return "+04"

```

Usage of KabulTz from above:

```

>>> tz1 = KabulTz()

>>> # Datetime before the change
>>> dt1 = datetime(1900, 11, 21, 16, 30, tzinfo=tz1)
>>> print(dt1.utcoffset())
4:00:00

>>> # Datetime after the change
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=tz1)
>>> print(dt2.utcoffset())
4:30:00

>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(timezone.utc)
>>> dt3
datetime.datetime(2006, 6, 14, 8, 30, tzinfo=datetime.ti
>>> dt2
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=KabulTz())

```

```
>>> dt2 == dt3
True
```

## time Objects

A **time** object represents a (local) time of day, independent of any particular day, and subject to adjustment via a **tzinfo** object.

```
class datetime.time(hour=0, minute=0, second=0, microsecond=0,
tzinfo=None, *, fold=0)
```

All arguments are optional. *tzinfo* may be `None`, or an instance of a **tzinfo** subclass. The remaining arguments must be integers in the following ranges:

- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold` in `[0, 1]`.

If an argument outside those ranges is given, **ValueError** is raised. All default to `0` except *tzinfo*, which defaults to **None**.

Class attributes:

**time.min**

The earliest representable **time**, `time(0, 0, 0, 0)`.

**time.max**

The latest representable **time**, `time(23, 59, 59, 999999)`.

**time.resolution**

The smallest possible difference between non-equal **time** objects, `timedelta(microseconds=1)`, although note that arithmetic on **time** objects is not supported.

Instance attributes (read-only):

`time.hour`

In `range(24)`.

`time.minute`

In `range(60)`.

`time.second`

In `range(60)`.

`time.microsecond`

In `range(1000000)`.

`time.tzinfo`

The object passed as the `tzinfo` argument to the `time` constructor, or `None` if none was passed.

`time.fold`

In `[0, 1]`. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The value 0 (1) represents the earlier (later) of the two moments with the same wall time representation.

*New in version 3.6.*

`time` objects support comparison of `time` to `time`, where  $a$  is considered less than  $b$  when  $a$  precedes  $b$  in time. If one comparand is naive and the other is aware, `TypeError` is raised if an order comparison is attempted. For equality comparisons, naive instances are never equal to aware instances.

If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`). In order to stop mixed-type comparisons

from falling back to the default comparison by object address, when a `time` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

*Changed in version 3.3:* Equality comparisons between aware and naive `time` instances don't raise `TypeError`.

In Boolean contexts, a `time` object is always considered to be true.

*Changed in version 3.5:* Before Python 3.5, a `time` object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See [bpo-13936](https://bugs.python.org/issue?@action=redirect&bpo=13936) [https://bugs.python.org/issue?@action=redirect&bpo=13936] for full details.

Other constructor:

*classmethod* `time.fromisoformat(time_string)`

Return a `time` corresponding to a `time_string` in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The leading `T`, normally required in cases where there may be ambiguity between a date and a time, is not required.
3. Fractional seconds may have any number of digits (anything beyond 6 will be truncated).
4. Fractional hours and minutes are not supported.

Examples:

```
>>> from datetime import time
>>> time.fromisoformat('04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T042301')
datetime.time(4, 23, 1)
>>> time.fromisoformat('04:23:01.000384')
```

```

datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01,000')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01+04:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone(da
>>> time.fromisoformat('04:23:01Z')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.ut
>>> time.fromisoformat('04:23:01+00:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.ut

```

*New in version 3.7.*

*Changed in version 3.11:* Previously, this method only supported formats that could be emitted by `time.isoformat()`.

Instance methods:

`time.replace(hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *, fold=0)`

Return a `time` with the same value, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive `time` from an aware `time`, without conversion of the time data.

*New in version 3.6:* Added the `fold` argument.

`time.isoformat(timespec='auto')`

Return a string representing the time in ISO 8601 format, one of:

- HH:MM:SS.ffffff, if `microsecond` is not 0
- HH:MM:SS, if `microsecond` is 0
- HH:MM:SS.ffffff+HH:MM[:SS[.ffffff]], if `utcoffset()` does not return `None`
- HH:MM:SS+HH:MM[:SS[.ffffff]], if `microsecond` is 0 and `utcoffset()` does not return

None

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if **microsecond** is 0, same as 'microseconds' otherwise.
- 'hours': Include the **hour** in the two-digit HH format.
- 'minutes': Include **hour** and **minute** in HH:MM format.
- 'seconds': Include **hour**, **minute**, and **second** in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.ffffff format.

### Note

Excluded time components are truncated, not rounded.

**ValueError** will be raised on an invalid *timespec* argument.

Example:

```
>>> from datetime import time
>>> time(hour=12, minute=34, second=56, microsecond=0)
'12:34'
>>> dt = time(hour=12, minute=34, second=56, microsecond=0)
>>> dt.isoformat(timespec='microseconds')
'12:34:56.000000'
>>> dt.isoformat(timespec='auto')
'12:34:56'
```

*New in version 3.6:* Added the *timespec* argument.

`time._str_()`

For a time `t`, `str(t)` is equivalent to `t.isoformat()`.

`time.strftime(format)`

Return a string representing the time, controlled by an explicit format string. See also [strftime\(\)](#) and [strptime\(\) Behavior](#) and [time.isoformat\(\)](#).

`time._format_(format)`

Same as [time.strftime\(\)](#). This makes it possible to specify a format string for a [time](#) object in [formatted string literals](#) and when using [str.format\(\)](#). See also [strftime\(\)](#) and [strptime\(\) Behavior](#) and [time.isoformat\(\)](#).

`time.utcoffset()`

If [tzinfo](#) is `None`, returns `None`, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return `None` or a [timedelta](#) object with magnitude less than one day.

*Changed in version 3.7:* The UTC offset is not restricted to a whole number of minutes.

`time.dst()`

If [tzinfo](#) is `None`, returns `None`, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return `None`, or a [timedelta](#) object with magnitude less than one day.

*Changed in version 3.7:* The DST offset is not restricted to a whole number of minutes.

`time.tzname()`

If [tzinfo](#) is `None`, returns `None`, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return `None` or a string object.

**Examples of Usage:** [time](#)

Examples of working with a **time** object:

```
>>> from datetime import time, tzinfo, timedelta
>>> class TZ1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self, dt):
...         return "+01:00"
...     def __repr__(self):
...         return f"{self.__class__.__name__}()"
...
>>> t = time(12, 10, 30, tzinfo=TZ1())
>>> t
datetime.time(12, 10, 30, tzinfo=TZ1())
>>> t.isoformat()
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'+01:00'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 +01:00'
>>> 'The {} is {:H:%M}.'.format("time", t)
'The time is 12:10.'
```

## **tzinfo** Objects

*class* datetime.tzinfo

This is an abstract base class, meaning that this class should not be instantiated directly. Define a subclass of **tzinfo** to capture information about a particular time zone.

An instance of (a concrete subclass of) **tzinfo** can be passed to the constructors for **datetime** and **time** objects. The latter objects view their attributes as being in local time, and the **tzinfo** object supports methods revealing offset of local

time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

You need to derive a concrete subclass, and (at least) supply implementations of the standard `tzinfo` methods needed by the `datetime` methods you use. The `datetime` module provides `timezone`, a simple concrete subclass of `tzinfo` which can represent timezones with fixed offset from UTC such as UTC itself or North American EST and EDT.

Special requirement for pickling: A `tzinfo` subclass must have an `__init__()` method that can be called with no arguments, otherwise it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of `tzinfo` may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware `datetime` objects. If in doubt, simply implement all of them.

#### `tzinfo.utcoffset(dt)`

Return offset of local time from UTC, as a `timedelta` object that is positive east of UTC. If local time is west of UTC, this should be negative.

This represents the *total* offset from UTC; for example, if a `tzinfo` object represents both time zone and DST adjustments, `utcoffset()` should return their sum. If the UTC offset isn't known, return `None`. Else the value returned must be a `timedelta` object strictly between `-timedelta(hours=24)` and `timedelta(hours=24)` (the magnitude of the offset must be less than one day). Most implementations of `utcoffset()` will probably look like one of these two:

```
return CONSTANT                                # fixed-offset class
return CONSTANT + self.dst(dt)                 # daylight-aware class
```

If `utcoffset()` does not return `None`, `dst()` should not

return None either.

The default implementation of `utcoffset()` raises `NotImplementedError`.

*Changed in version 3.7:* The UTC offset is not restricted to a whole number of minutes.

`tzinfo.dst(dt)`

Return the daylight saving time (DST) adjustment, as a `timedelta` object or `None` if DST information isn't known.

Return `timedelta(0)` if DST is not in effect. If DST is in effect, return the offset as a `timedelta` object (see `utcoffset()` for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by `utcoffset()`, so there's no need to consult `dst()` unless you're interested in obtaining DST info separately. For example, `datetime.timetuple()` calls its `tzinfo` attribute's `dst()` method to determine how the `tm_isdst` flag should be set, and `tzinfo.fromutc()` calls `dst()` to account for DST changes when crossing time zones.

An instance `tz` of a `tzinfo` subclass that models both standard and daylight times must be consistent in this sense:

```
tz.utcoffset(dt) - tz.dst(dt)
```

must return the same result for every `datetime dt` with `dt.tzinfo == tz`. For sane `tzinfo` subclasses, this expression yields the time zone's "standard offset", which should not depend on the date or the time, but only on geographic location. The implementation of `datetime.astimezone()` relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a `tzinfo` subclass cannot guarantee this, it may be able to override the default implementation of `tzinfo.fromutc()` to work correctly with `astimezone()` regardless.

Most implementations of `dst()` will probably look like one of these two:

```
def dst(self, dt):
    # a fixed-offset class:  doesn't account for DST
    return timedelta(0)
```

or:

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone
    # transition times based on the input dt.year,
    # in standard local time.

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

The default implementation of `dst()` raises `NotImplementedError`.

*Changed in version 3.7:* The DST offset is not restricted to a whole number of minutes.

`tzinfo.tzname(dt)`

Return the time zone name corresponding to the `datetime` object `dt`, as a string. Nothing about string names is defined by the `datetime` module, and there's no requirement that it mean anything in particular. For example, "GMT", "UTC", "-500", "-5:00", "EDT", "US/Eastern", "America/New York" are all valid replies. Return `None` if a string name isn't known. Note that this is a method rather than a fixed string primarily because some `tzinfo` subclasses will wish to return different names depending on the specific value of `dt` passed, especially if the `tzinfo` class is accounting for daylight time.

The default implementation of `tzname()` raises `NotImplementedError`.

These methods are called by a `datetime` or `time` object, in response to their methods of the same names. A `datetime` object

passes itself as the argument, and a `time` object passes `None` as the argument. A `tzinfo` subclass's methods should therefore be prepared to accept a `dt` argument of `None`, or of class `datetime`.

When `None` is passed, it's up to the class designer to decide the best response. For example, returning `None` is appropriate if the class wishes to say that time objects don't participate in the `tzinfo` protocols. It may be more useful for `utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a `datetime` object is passed in response to a `datetime` method, `dt.tzinfo` is the same object as `self`. `tzinfo` methods can rely on this, unless user code calls `tzinfo` methods directly. The intent is that the `tzinfo` methods interpret `dt` as being in local time, and not need worry about objects in other timezones.

There is one more `tzinfo` method that a subclass may wish to override:

`tzinfo.fromutc(dt)`

This is called from the default `datetime.astimezone()` implementation. When called from that, `dt.tzinfo` is `self`, and `dt`'s date and time data are to be viewed as expressing a UTC time. The purpose of `fromutc()` is to adjust the date and time data, returning an equivalent datetime in `self`'s local time.

Most `tzinfo` subclasses should be able to inherit the default `fromutc()` implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default `fromutc()` implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations of `astimezone()` and `fromutc()` may not produce the result you want if the result is one of the hours straddling the moment the standard offset

changes.

Skipping code for error cases, the default `fromutc()` implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not se
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is
    delta = dtoff - dtdst # this is self's standar
    if delta:
        dt += delta # convert to standard local t
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

In the following `tzinfo_examples.py` file there are some examples of `tzinfo` classes:

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)
SECOND = timedelta(seconds=1)

# A class capturing the platform's idea of local time.
# (May result in wrong values on historical times in
# timezones where UTC offset and/or the DST rules had
# changed in the past.)
import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
```

```
DSTOFFSET = STDOFFSET
```

```
DSTDIFF = DSTOFFSET - STDOFFSET
```

```
class LocalTimezone(tzinfo):
```

```
    def fromutc(self, dt):
        assert dt.tzinfo is self
        stamp = (dt - datetime(1970, 1, 1, tzinfo=self)).total_seconds()
        args = _time.localtime(stamp)[:6]
        dst_diff = DSTDIFF // SECOND
        # Detect fold
        fold = (args == _time.localtime(stamp - dst_diff))
        return datetime(*args, microsecond=dt.microsecond,
                        tzinfo=self, fold=fold)

    def utcoffset(self, dt):
        if self._isdst(dt):
            return DSTOFFSET
        else:

```

```

def fromutc(self, dt):
    assert dt.tzinfo is self
    start, end = us_dst_range(dt.year)
    start = start.replace(tzinfo=self)
    end = end.replace(tzinfo=self)
    std_time = dt + self.stdoffset
    dst_time = std_time + HOUR
    if end <= dst_time < end + HOUR:
        # Repeated hour
        return std_time.replace(fold=1)
    if std_time < start or dst_time >= end:
        # Standard time
        return std_time
    if start <= std_time < end - HOUR:
        # Daylight saving time

```

```
return dst_time
```

```
Eastern = USTimeZone(-5, "Eastern", "EST", "EDT")
Central = USTimeZone(-6, "Central", "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific = USTimeZone(-8, "Pacific", "PST", "PDT")
```

Note that there are unavoidable subtleties twice per year in a `tzinfo` subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

|       |       |       |      |      |      |      |
|-------|-------|-------|------|------|------|------|
| UTC   | 3:MM  | 4:MM  | 5:MM | 6:MM | 7:MM | 8:MM |
| EST   | 22:MM | 23:MM | 0:MM | 1:MM | 2:MM | 3:MM |
| EDT   | 23:MM | 0:MM  | 1:MM | 2:MM | 3:MM | 4:MM |
| start | 22:MM | 23:MM | 0:MM | 1:MM | 3:MM | 4:MM |
| end   | 23:MM | 0:MM  | 1:MM | 1:MM | 2:MM | 3:MM |

When DST starts (the “start” line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn’t really make sense on that day, so `astimezone(Eastern)` won’t deliver a result with `hour == 2` on the day DST begins. For example, at the Spring forward transition of 2016, we get:

```
>>> from datetime import datetime, timezone
>>> from tzinfo_examples import HOUR, Eastern
>>> u0 = datetime(2016, 3, 13, 5, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname())
...
05:00:00 UTC = 00:00:00 EST
06:00:00 UTC = 01:00:00 EST
07:00:00 UTC = 03:00:00 EDT
```

08:00:00 UTC = 04:00:00 EDT

When DST ends (the “end” line), there’s a potentially worse problem: there’s an hour that can’t be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that’s times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. `astimezone()` mimics the local clock’s behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern, but earlier times have the `fold` attribute set to 0 and the later times have it set to 1. For example, at the Fall back transition of 2016, we get:

```
>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname(), t.fold)
...
04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0
```

Note that the `datetime` instances that differ only by the value of the `fold` attribute are considered equal in comparisons.

Applications that can’t bear wall-time ambiguities should explicitly check the value of the `fold` attribute or avoid using hybrid `tzinfo` subclasses; there are no ambiguities when using `timezone`, or any other fixed-offset `tzinfo` subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

See also

`zoneinfo`

The `datetime` module has a basic

`timezone` class (for handling arbitrary fixed offsets from UTC) and its `timezone.utc` attribute (a UTC timezone instance).

`zoneinfo` brings the *IANA timezone database* (also known as the Olson database) to Python, and its usage is recommended.

### IANA timezone database [https://www.iana.org/time-zones]

The Time Zone Database (often called tz, tzdata or zoneinfo) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

## timezone Objects

The `timezone` class is a subclass of `tzinfo`, each instance of which represents a timezone defined by a fixed offset from UTC.

Objects of this class cannot be used to represent timezone information in the locations where different offsets are used in different days of the year or where historical changes have been made to civil time.

`class datetime.timezone(offset, name=None)`

The `offset` argument must be specified as a `timedelta` object representing the difference between the local time and UTC. It must be strictly between `-timedelta(hours=24)` and `timedelta(hours=24)`, otherwise `ValueError` is raised.

The `name` argument is optional. If specified it must be a string that will be used as the value returned by the `datetime.tzname()` method.

*New in version 3.2.*

*Changed in version 3.7:* The UTC offset is not restricted to a whole number of minutes.

`timezone.utcoffset(dt)`

Return the fixed value specified when the `timezone` instance is constructed.

The `dt` argument is ignored. The return value is a `timedelta` instance equal to the difference between the local time and UTC.

*Changed in version 3.7:* The UTC offset is not restricted to a whole number of minutes.

`timezone.tzname(dt)`

Return the fixed value specified when the `timezone` instance is constructed.

If `name` is not provided in the constructor, the name returned by `tzname(dt)` is generated from the value of the `offset` as follows. If `offset` is `timedelta(0)`, the name is “UTC”, otherwise it is a string in the format `UTC±HH:MM`, where  $\pm$  is the sign of `offset`, HH and MM are two digits of `offset.hours` and `offset.minutes` respectively.

*Changed in version 3.6:* Name generated from `offset=timedelta(0)` is now plain `'UTC'`, not `'UTC+00:00'`.

`timezone.dst(dt)`

Always returns `None`.

`timezone.fromutc(dt)`

Return `dt + offset`. The `dt` argument must be an aware `datetime` instance, with `tzinfo` set to `self`.

Class attributes:

`timezone.utc`

The UTC timezone, `timezone(timedelta(0))`.

## **strftime() and strptime() Behavior**

`date`, `datetime`, and `time` objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string.

Conversely, the `datetime.strptime()` class method creates a `datetime` object from a string representing a date and time and a corresponding format string.

The table below provides a high-level comparison of `strftime()` versus `strptime()`:

|                                                                          |                                                                   |
|--------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>strftime</b>                                                          |                                                                   |
| Converts object to a string according to a given format                  | Converts string to a datetime object given a corresponding format |
| Class method                                                             | Class method                                                      |
| Method of: <code>date</code> ; <code>datetime</code> ; <code>time</code> | Method of: <code>datetime</code>                                  |
| Signature: <code>strftime(formatstring, format)</code>                   | Signature: <code>datetime.strptime(string, format)</code>         |

## **strftime() and strptime() Format Codes**

These methods accept format codes that can be used to parse and format dates:

```
>>> datetime.strptime('31/01/22 23:59:59.999999',
...                    '%d/%m/%y %H:%M:%S.%f')
datetime.datetime(2022, 1, 31, 23, 59, 59, 999999)
>>> _.strftime('%a %d %b %Y, %I:%M%p')
'Mon 31 Jan 2022, 11:59PM'
```

The following is a list of all the format codes that the 1989 C standard requires, and these work on all platforms with a standard C implementation.

## Notespielge

Week 10, as. lose sale (email) abbreviated name.

So, Mo, ..., Sa (de\_DE)

Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday. (en\_US);

Sonntag, Montag, ..., Samstag (de\_DE)

Weekday is a decimal number, where 0 is Sunday and 6 is Saturday.

0001, the month as a zero-padded decimal number.

Montreal's local's (ambles);ated name.

Jan, Feb, ..., Dez (de\_DE)

~~Month~~ as Hobbes's full name December (en\_US);

Januar, Februar, ..., Dezember (de\_DE)

01) not, as a zero-padded decimal number.

00,01 with 00 century as a zero-padded decimal number.

1001, 1002, century 2013, a 2014, mal, number 9999

0001(24:hr clock) as a zero-padded decimal number.

0000212.102r clock) as a zero-padded decimal number.

**AM, PM (equivalent)** of either AM or PM.

am, pm (de\_DE)

001101, as a zero-padded decimal number.

as a zero-padded decimal number.

000000second as a decimal number, zero-padded to 6 digits.

(6) if (poff) set = 0000, for 40, ±H1030, SH[063415, F0307chp345216 if the object is naive).

**Time** (Empty string if the object is naive).

001, of 02, the year as a zero-padded decimal number.

Week number of the year (Sunday as the first day of the week) as a zero-padded decimal number. All days in a new year preceding the first Sunday are considered to be in week 0.

Week number of the year (Monday as the first day of the week) as a zero-padded decimal number. All days in a new year preceding the first Monday are considered to be in week 0.

The Aug 16 21 31 00 1988 (entire) representation.

Di 16 Aug 21:30:00 1988 (de\_DE)

08/16/88 (Nope) date representation.

08/16/1988 (en\_US);

16.08.1988 (de\_DE)

21340-30 (propose) date time representation.

21:30:00 (de\_DE)

**%** literal `' % '` character.

Several additional directives not required by the C89 standard are included for convenience. These parameters all correspond to ISO 8601 date values.

### Notesfile

---

**%Y** ISO 8601 year, with 3 or 4, representing the year that contains the greater part of the ISO week (**%V**).

---

**%j** ISO 8601 weekday as a decimal number where 1 is Monday.

---

**%U** ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4.

---

These may not be available on all platforms when used with the **strptime()** method. The ISO 8601 year and ISO 8601 week directives are not interchangeable with the year and week number directives above. Calling **strptime()** with incomplete or ambiguous ISO 8601 directives will raise a **ValueError**.

The full set of format codes supported varies across platforms, because Python calls the platform C library's **strptime()** function, and platform variations are common. To see the full set of format codes supported on your platform, consult the [strptime\(3\)](#) documentation. There are also differences between platforms in handling of unsupported format specifiers.

*New in version 3.6:* **%G**, **%u** and **%V** were added.

## Technical Detail

Broadly speaking, **d.strptime(fmt)** acts like the **time** module's **time.strptime(fmt, d.timetuple())** although not all objects support a **timetuple()** method.

For the **datetime.strptime()** class method, the default value is 1900-01-01T00:00:00.000: any components not specified in the format string will be pulled from the default value. [4](#)

Using **datetime.strptime(date\_string, format)** is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

except when the format includes sub-second components or timezone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

For `time` objects, the format codes for year, month, and day should not be used, as `time` objects have no such values. If they're used anyway, 1900 is substituted for the year, and 1 for the month and day.

For `date` objects, the format codes for hours, minutes, seconds, and microseconds should not be used, as `date` objects have no such values. If they're used anyway, 0 is substituted for them.

For the same reason, handling of format strings containing Unicode code points that can't be represented in the charset of the current locale is also platform-dependent. On some platforms such code points are preserved intact in the output, while on others `strptime` may raise `UnicodeError` or return an empty string instead.

Notes:

1. Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, “month/day/year” versus “day/month/year”), and the output may contain non-ASCII characters.
2. The `strptime()` method can parse years in the full [1, 9999] range, but years < 1000 must be zero-filled to 4-digit width.

*Changed in version 3.2:* In previous versions, `strptime()` method was restricted to years  $\geq 1900$ .

*Changed in version 3.3:* In version 3.2, `strptime()` method was restricted to years  $\geq 1000$ .

3. When used with the `strptime()` method, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.

4. Unlike the `time` module, the `datetime` module does not support leap seconds.
5. When used with the `strptime()` method, the `%f` directive accepts from one to six digits and zero pads on the right. `%f` is an extension to the set of format characters in the C standard (but implemented separately in datetime objects, and therefore always available).
6. For a naive object, the `%z` and `%Z` format codes are replaced by empty strings.

For an aware object:

`%z`

`utcoffset()` is transformed into a string of the form `±HHMM[SS[.ffffff]]`, where `HH` is a 2-digit string giving the number of UTC offset hours, `MM` is a 2-digit string giving the number of UTC offset minutes, `SS` is a 2-digit string giving the number of UTC offset seconds and `ffffff` is a 6-digit string giving the number of UTC offset microseconds. The `ffffff` part is omitted when the offset is a whole number of seconds and both the `ffffff` and the `SS` part is omitted when the offset is a whole number of minutes. For example, if `utcoffset()` returns `timedelta(hours=-3, minutes=-30)`, `%z` is replaced with the string `'-0330'`.

*Changed in version 3.7:* The UTC offset is not restricted to a whole number of minutes.

*Changed in version 3.7:* When the `%z` directive is provided to the `strptime()` method, the UTC offsets can have a colon as a separator between hours, minutes and seconds. For example, `'+01:00:00'` will be parsed as an offset of one hour. In addition, providing `'Z'` is identical to `'+00:00'`.

`%Z`

In `strptime()`, `%Z` is replaced by an empty string if `tzname()` returns `None`; otherwise `%Z` is replaced by

the returned value, which must be a string.

**strptime()** only accepts certain values for `%Z`:

1. any value in `time.tzname` for your machine's locale
2. the hard-coded values `UTC` and `GMT`

So someone living in Japan may have `JST`, `UTC`, and `GMT` as valid values, but probably not `EST`. It will raise `ValueError` for invalid values.

*Changed in version 3.2:* When the `%z` directive is provided to the **strptime()** method, an aware `datetime` object will be produced. The `tzinfo` of the result will be set to a `timezone` instance.

7. When used with the **strptime()** method, `%U` and `%W` are only used in calculations when the day of the week and the calendar year (`%Y`) are specified.
8. Similar to `%U` and `%W`, `%V` is only used in calculations when the day of the week and the ISO year (`%G`) are specified in a **strptime()** format string. Also note that `%G` and `%Y` are not interchangeable.
9. When used with the **strptime()** method, the leading zero is optional for formats `%d`, `%m`, `%H`, `%I`, `%M`, `%S`, `%j`, `%U`, `%W`, and `%V`. Format `%Y` does require a leading zero.

## Footnotes

1

If, that is, we ignore the effects of Relativity

2

This matches the definition of the “proleptic Gregorian” calendar in Dershowitz and Reingold’s book *Calendrical Calculations*, where it’s the base calendar for all computations.

See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

3

See R. H. van Gent's [guide to the mathematics of the ISO 8601 calendar](https://web.archive.org/web/20220531051136/https://webspacescience.uu.nl/~gent0113/calendar/isocalendar.htm) [https://web.archive.org/web/20220531051136/https://webspacescience.uu.nl/~gent0113/calendar/isocalendar.htm] for a good explanation.

4

Passing `datetime.strptime('Feb 29', '%b %d')` will fail since 1900 is not a leap year.

# zoneinfo — IANA time zone support

*New in version 3.9.*

**Source code:** [Lib/zoneinfo](https://github.com/python/cpython/tree/3.11/Lib/zoneinfo) [https://github.com/python/cpython/tree/3.11/Lib/zoneinfo]

---

The **zoneinfo** module provides a concrete time zone implementation to support the IANA time zone database as originally specified in [PEP 615](https://peps.python.org/pep-0615/) [https://peps.python.org/pep-0615/]. By default, **zoneinfo** uses the system's time zone data if available; if no system time zone data is available, the library will fall back to using the first-party [tzdata](https://pypi.org/project/tzdata/) [https://pypi.org/project/tzdata/] package available on PyPI.

## See also

### Module: **datetime**

Provides the **time** and **datetime** types with which the **ZoneInfo** class is designed to be used.

### Package **tzdata** [https://pypi.org/project/tzdata/]

First-party package maintained by the CPython core developers to supply time zone data via PyPI.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Using **ZoneInfo**

`ZoneInfo` is a concrete implementation of the `datetime.tzinfo` abstract base class, and is intended to be attached to `tzinfo`, either via the constructor, the `datetime.replace` method or `datetime.astimezone`:

```
>>> from zoneinfo import ZoneInfo
>>> from datetime import datetime, timedelta

>>> dt = datetime(2020, 10, 31, 12, tzinfo=ZoneInfo("America/New_York"))
>>> print(dt)
2020-10-31 12:00:00-07:00

>>> dt.tzname()
'PDT'
```

Datetimes constructed in this way are compatible with datetime arithmetic and handle daylight saving time transitions with no further intervention:

```
>>> dt_add = dt + timedelta(days=1)

>>> print(dt_add)
2020-11-01 12:00:00-08:00

>>> dt_add.tzname()
'PST'
```

These time zones also support the `fold` attribute introduced in [PEP 495](https://peps.python.org/pep-0495/) [https://peps.python.org/pep-0495/]. During offset transitions which induce ambiguous times (such as a daylight saving time to standard time transition), the offset from *before* the transition is used when `fold=0`, and the offset *after* the transition is used when `fold=1`, for example:

```
>>> dt = datetime(2020, 11, 1, 1, tzinfo=ZoneInfo("America/New_York"))
>>> print(dt)
2020-11-01 01:00:00-07:00

>>> print(dt.replace(fold=1))
2020-11-01 01:00:00-08:00
```

When converting from another time zone, the fold will be set to the correct value:

```
>>> from datetime import timezone
>>> LOS_ANGELES = ZoneInfo("America/Los_Angeles")
>>> dt_utc = datetime(2020, 11, 1, 8, tzinfo=timezone.utc)

>>> # Before the PDT -> PST transition
>>> print(dt_utc.astimezone(LOS_ANGELES))
2020-11-01 01:00:00-07:00

>>> # After the PDT -> PST transition
>>> print((dt_utc + timedelta(hours=1)).astimezone(LOS_ANGELES))
2020-11-01 01:00:00-08:00
```

## Data sources

The `zoneinfo` module does not directly provide time zone data, and instead pulls time zone information from the system time zone database or the first-party PyPI package [tzdata](https://pypi.org/project/tzdata/) [https://pypi.org/project/tzdata/], if available. Some systems, including notably Windows systems, do not have an IANA database available, and so for projects targeting cross-platform compatibility that require time zone data, it is recommended to declare a dependency on `tzdata`. If neither system data nor `tzdata` are available, all calls to `ZoneInfo` will raise `ZoneInfoNotFoundError`.

## Configuring the data sources

When `ZoneInfo(key)` is called, the constructor first searches the directories specified in `TZPATH` for a file matching `key`, and on failure looks for a match in the `tzdata` package. This behavior can be configured in three ways:

1. The default `TZPATH` when not otherwise specified can be configured at [compile time](#).
2. `TZPATH` can be configured using [an environment variable](#).
3. At [runtime](#), the search path can be manipulated using the `reset_tzpath()` function.

## Compile-time configuration

The default `TZPATH` includes several common deployment locations for the time zone database (except on Windows, where there are no “well-known” locations for time zone data). On POSIX systems, downstream distributors and those building Python from source who know where their system time zone data is deployed may change the default time zone path by specifying the compile-time option `TZPATH` (or, more likely, the **configure flag `--with-tzpath`**), which should be a string delimited by `os.pathsep`.

On all platforms, the configured value is available as the `TZPATH` key in `sysconfig.get_config_var()`.

## Environment configuration

When initializing `TZPATH` (either at import time or whenever `reset_tzpath()` is called with no arguments), the `zoneinfo` module will use the environment variable `PYTHONTZPATH`, if it exists, to set the search path.

### PYTHONTZPATH

This is an `os.pathsep`-separated string containing the time zone search path to use. It must consist of only absolute rather than relative paths. Relative components specified in `PYTHONTZPATH` will not be used, but otherwise the behavior when a relative path is specified is implementation-defined; CPython will raise `InvalidTZPathWarning`, but other implementations are free to silently ignore the erroneous component or raise an exception.

To set the system to ignore the system data and use the `tzdata` package instead, set `PYTHONTZPATH=""`.

## Runtime configuration

The TZ search path can also be configured at runtime using the `reset_tzpath()` function. This is generally not an advisable

operation, though it is reasonable to use it in test functions that require the use of a specific time zone path (or require disabling access to the system time zones).

## The `ZoneInfo` class

*class* `zoneinfo.ZoneInfo(key)`

A concrete `datetime.tzinfo` subclass that represents an IANA time zone specified by the string `key`. Calls to the primary constructor will always return objects that compare identically; put another way, barring cache invalidation via `ZoneInfo.clear_cache()`, for all values of `key`, the following assertion will always be true:

```
a = ZoneInfo(key)
b = ZoneInfo(key)
assert a is b
```

`key` must be in the form of a relative, normalized POSIX path, with no up-level references. The constructor will raise `ValueError` if a non-conforming key is passed.

If no file matching `key` is found, the constructor will raise `ZoneInfoNotFoundError`.

The `ZoneInfo` class has two alternate constructors:

*classmethod* `ZoneInfo.from_file(fobj, /, key=None)`

Constructs a `ZoneInfo` object from a file-like object returning bytes (e.g. a file opened in binary mode or an `io.BytesIO` object). Unlike the primary constructor, this always constructs a new object.

The `key` parameter sets the name of the zone for the purposes of `__str__()` and `__repr__()`.

Objects created via this constructor cannot be pickled (see [pickling](#)).

*classmethod* `ZoneInfo.no_cache(key)`

An alternate constructor that bypasses the constructor's cache. It is identical to the primary constructor, but returns a new object on each call. This is most likely to be useful for testing or demonstration purposes, but it can also be used to create a system with a different cache invalidation strategy.

Objects created via this constructor will also bypass the cache of a deserializing process when unpickled.

### **Caution**

Using this constructor may change the semantics of your datetimes in surprising ways, only use it if you know that you need to.

The following class methods are also available:

*classmethod* `ZoneInfo.clear_cache(*, only_keys=None)`

A method for invalidating the cache on the `ZoneInfo` class. If no arguments are passed, all caches are invalidated and the next call to the primary constructor for each key will return a new instance.

If an iterable of key names is passed to the `only_keys` parameter, only the specified keys will be removed from the cache. Keys passed to `only_keys` but not found in the cache are ignored.

### **Warning**

Invoking this function may change the semantics of datetimes using `ZoneInfo` in surprising ways; this modifies process-wide global state and thus may have wide-ranging effects. Only use it if you know that you need to.

The class has one attribute:

### ZoneInfo.key

This is a read-only [attribute](#) that returns the value of `key` passed to the constructor, which should be a lookup key in the IANA time zone database (e.g. `America/New_York`, `Europe/Paris` or `Asia/Tokyo`).

For zones constructed from file without specifying a `key` parameter, this will be set to `None`.

### Note

Although it is a somewhat common practice to expose these to end users, these values are designed to be primary keys for representing the relevant zones and not necessarily user-facing elements. Projects like CLDR (the Unicode Common Locale Data Repository) can be used to get more user-friendly strings from these keys.

## String representations

The string representation returned when calling `str` on a `ZoneInfo` object defaults to using the `ZoneInfo.key` attribute (see the note on usage in the attribute documentation):

```
>>> zone = ZoneInfo("Pacific/Kwajalein")
>>> str(zone)
'Pacific/Kwajalein'

>>> dt = datetime(2020, 4, 1, 3, 15, tzinfo=zone)
>>> f"{dt.isoformat()} [{dt.tzinfo}]"
'2020-04-01T03:15:00+12:00 [Pacific/Kwajalein]'
```

For objects constructed from a file without specifying a `key` parameter, `str` falls back to calling `repr()`. `ZoneInfo`'s `repr` is implementation-defined and not necessarily stable between versions, but it is guaranteed not to be a valid `ZoneInfo` key.

## Pickle serialization

Rather than serializing all transition data, `ZoneInfo` objects are serialized by key, and `ZoneInfo` objects constructed from files (even those with a value for `key` specified) cannot be pickled.

The behavior of a `ZoneInfo` file depends on how it was constructed:

1. `ZoneInfo(key)`: When constructed with the primary constructor, a `ZoneInfo` object is serialized by key, and when deserialized, the deserializing process uses the primary and thus it is expected that these are expected to be the same object as other references to the same time zone. For example, if `europe_berlin_pkl` is a string containing a pickle constructed from `ZoneInfo("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl)
>>> a is b
True
```

2. `ZoneInfo.no_cache(key)`: When constructed from the cache-bypassing constructor, the `ZoneInfo` object is also serialized by key, but when deserialized, the deserializing process uses the cache bypassing constructor. If `europe_berlin_pkl_nc` is a string containing a pickle constructed from `ZoneInfo.no_cache("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl_nc)
>>> a is b
False
```

3. `ZoneInfo.from_file(fobj, /, key=None)`: When constructed from a file, the `ZoneInfo` object raises an exception on pickling. If an end user wants to pickle a `ZoneInfo` constructed from a file, it is recommended that

they use a wrapper type or a custom serialization function: either serializing by key or storing the contents of the file object and serializing that.

This method of serialization requires that the time zone data for the required key be available on both the serializing and deserializing side, similar to the way that references to classes and functions are expected to exist in both the serializing and deserializing environments. It also means that no guarantees are made about the consistency of results when unpickling a `ZoneInfo` pickled in an environment with a different version of the time zone data.

## Functions

`zoneinfo.available_timezones()`

Get a set containing all the valid keys for IANA time zones available anywhere on the time zone path. This is recalculated on every call to the function.

This function only includes canonical zone names and does not include “special” zones such as those under the `posix/` and `right/` directories, or the `posixrules` zone.

### Caution

This function may open a large number of files, as the best way to determine if a file on the time zone path is a valid time zone is to read the “magic string” at the beginning.

### Note

These values are not designed to be exposed to end-users; for user facing elements, applications should use something like CLDR (the Unicode Common Locale Data Repository) to get more user-friendly strings. See also the cautionary note on [`ZoneInfo.key`](#).

`zoneinfo.reset_tzpath(to = None)`

Sets or resets the time zone search path (**TZPATH**) for the module. When called with no arguments, **TZPATH** is set to the default value.

Calling `reset_tzpath` will not invalidate the **ZoneInfo** cache, and so calls to the primary **ZoneInfo** constructor will only use the new **TZPATH** in the case of a cache miss.

The `to` parameter must be a **sequence** of strings or **os.PathLike** and not a string, all of which must be absolute paths. **ValueError** will be raised if something other than an absolute path is passed.

## Globals

### `zoneinfo.TZPATH`

A read-only sequence representing the time zone search path – when constructing a **ZoneInfo** from a key, the key is joined to each entry in the **TZPATH**, and the first file found is used.

**TZPATH** may contain only absolute paths, never relative paths, regardless of how it is configured.

The object that `zoneinfo.TZPATH` points to may change in response to a call to `reset_tzpath()`, so it is recommended to use `zoneinfo.TZPATH` rather than importing **TZPATH** from `zoneinfo` or assigning a long-lived variable to `zoneinfo.TZPATH`.

For more information on configuring the time zone search path, see [Configuring the data sources](#).

## Exceptions and warnings

### *exception* `zoneinfo.ZoneInfoNotFoundError`

Raised when construction of a **ZoneInfo** object fails because the specified key could not be found on the system. This is a subclass of **KeyError**.

*exception* zoneinfo.InvalidTZPathWarning

Raised when **PYTHONTZPATH** contains an invalid component that will be filtered out, such as a relative path.

# calendar — General calendar-related functions

**Source code:** [Lib/calendar.py](https://github.com/python/cpython/tree/3.11/Lib/calendar.py) [https://github.com/python/cpython/tree/3.11/Lib/calendar.py]

---

This module allows you to output calendars like the Unix **cal** program, and provides additional useful functions related to the calendar. By default, these calendars have Monday as the first day of the week, and Sunday as the last (the European convention). Use **setfirstweekday()** to set the first day of the week to Sunday (6) or to any other weekday. Parameters that specify dates are given as integers. For related functionality, see also the **datetime** and **time** modules.

The functions and classes defined in this module use an idealized calendar, the current Gregorian calendar extended indefinitely in both directions. This matches the definition of the “proleptic Gregorian” calendar in Dershowitz and Reingold’s book “Calendrical Calculations”, where it’s the base calendar for all computations. Zero and negative years are interpreted as prescribed by the ISO 8601 standard. Year 0 is 1 BC, year -1 is 2 BC, and so on.

*class* **calendar.Calendar**(*firstweekday=0*)

Creates a **Calendar** object. *firstweekday* is an integer specifying the first day of the week. **MONDAY** is 0 (the default), **SUNDAY** is 6.

A **Calendar** object provides several methods that can be used for preparing the calendar data for formatting. This class doesn’t do any formatting itself. This is the job of subclasses.

**Calendar** instances have the following methods:

`iterweekdays()`

Return an iterator for the week day numbers that will be used for one week. The first value from the iterator will be the same as the value of the `firstweekday` property.

`itermonthdates(year, month)`

Return an iterator for the month *month* (1–12) in the year *year*. This iterator will return all days (as `datetime.date` objects) for the month and all days before the start of the month or after the end of the month that are required to get a complete week.

`itermonthdays(year, month)`

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will simply be day of the month numbers. For the days outside of the specified month, the day number is 0.

`itermonthdays2(year, month)`

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a day of the month number and a week day number.

`itermonthdays3(year, month)`

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a year, a month and a day of the month numbers.

*New in version 3.7.*

`itermonthdays4(year, month)`

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a year, a month, a day of the month, and a day of the week numbers.

*New in version 3.7.*

`monthdatescalendar(year, month)`

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven `datetime.date` objects.

`monthdays2calendar(year, month)`

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven tuples of day numbers and weekday numbers.

`monthdayscalendar(year, month)`

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven day numbers.

`yeardatescalendar(year, width=3)`

Return the data for the specified year ready for formatting. The return value is a list of month rows. Each month row contains up to *width* months (defaulting to 3). Each month contains between 4 and 6 weeks and each week contains 1–7 days. Days are `datetime.date` objects.

`yeardays2calendar(year, width=3)`

Return the data for the specified year ready for formatting (similar to `yeardatescalendar()`). Entries in the week lists are tuples of day numbers and weekday numbers. Day numbers outside this month are zero.

`yeardayscalendar(year, width=3)`

Return the data for the specified year ready for formatting (similar to `yeardatescalendar()`). Entries in the week lists are day numbers. Day numbers outside this month are zero.

`class calendar.TextCalendar(firstweekday=0)`

This class can be used to generate plain text calendars.

`TextCalendar` instances have the following methods:

`formatmonth(theyear, themonth, w=0, l=0)`

Return a month's calendar in a multi-line string. If *w* is provided, it specifies the width of the date columns, which are centered. If *l* is given, it specifies the number of lines that each week will use. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method.

`prmonth(theyear, themonth, w=0, l=0)`

Print a month's calendar as returned by `formatmonth()`.

`formatyear(theyear, w=2, l=1, c=6, m=3)`

Return a *m*-column calendar for an entire year as a multi-line string. Optional parameters *w*, *l*, and *c* are for date column width, lines per week, and number of spaces between month columns, respectively. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method. The earliest year for which a calendar can be generated is platform-dependent.

`pryear(theyear, w=2, l=1, c=6, m=3)`

Print the calendar for an entire year as returned by `formatyear()`.

`class calendar.HTMLCalendar(firstweekday=0)`

This class can be used to generate HTML calendars.

**HTMLCalendar** instances have the following methods:

`formatmonth(theyear, themonth, withyear=True)`

Return a month's calendar as an HTML table. If *withyear* is true the year will be included in the header, otherwise just the month name will be used.

`formatyear(theyear, width=3)`

Return a year's calendar as an HTML table. *width* (defaulting to 3) specifies the number of months per row.

`formatyearpage(theyear, width=3, css='calendar.css', encoding=None)`

Return a year's calendar as a complete HTML page. *width* (defaulting to 3) specifies the number of months per row. *css* is the name for the cascading style sheet to be used. **None** can be passed if no style sheet should be used. *encoding* specifies the encoding to be used for the output (defaulting to the system default encoding).

**HTMLCalendar** has the following attributes you can override to customize the CSS classes used by the calendar:

`cssclasses`

A list of CSS classes used for each weekday. The default class list is:

```
cssclasses = ["mon", "tue", "wed", "thu", "fri", "sat", "sun"]
```

more styles can be added for each day:

```
cssclasses = ["mon text-bold", "tue", "wed", "thu", "fri", "sat", "sun"]
```

Note that the length of this list must be seven items.

### `cssclass_noday`

The CSS class for a weekday occurring in the previous or coming month.

*New in version 3.7.*

### `cssclasses_weekday_head`

A list of CSS classes used for weekday names in the header row. The default is the same as `cssclasses`.

*New in version 3.7.*

### `cssclass_month_head`

The month's head CSS class (used by `formatmonthname()`). The default value is `"month"`.

*New in version 3.7.*

### `cssclass_month`

The CSS class for the whole month's table (used by `formatmonth()`). The default value is `"month"`.

*New in version 3.7.*

### `cssclass_year`

The CSS class for the whole year's table of tables (used by `formatyear()`). The default value is `"year"`.

*New in version 3.7.*

### `cssclass_year_head`

The CSS class for the table head for the whole year (used by `formatyear()`). The default value is `"year"`.

*New in version 3.7.*

Note that although the naming for the above described class

attributes is singular (e.g. `cssclass_month` `cssclass_noday`), one can replace the single CSS class with a space separated list of CSS classes, for example:

```
"text-bold text-red"
```

Here is an example how **HTMLCalendar** can be customized:

```
class CustomHTMLCal(calendar.HTMLCalendar):
    cssclasses = [style + " text-nowrap" for style
                  in calendar.HTMLCalendar.cssclasses]
    cssclass_month_head = "text-center month-head"
    cssclass_month = "text-center month"
    cssclass_year = "text-italic lead"
```

*class* `calendar.LocaleTextCalendar(firstweekday=0, locale=None)`

This subclass of **TextCalendar** can be passed a locale name in the constructor and will return month and weekday names in the specified locale.

*class* `calendar.LocaleHTMLCalendar(firstweekday=0, locale=None)`

This subclass of **HTMLCalendar** can be passed a locale name in the constructor and will return month and weekday names in the specified locale.

## Note

The constructor, **formatweekday()** and **formatmonthname()** methods of these two classes temporarily change the `LC_TIME` locale to the given *locale*. Because the current locale is a process-wide setting, they are not thread-safe.

For simple text calendars this module provides the following functions.

`calendar.setfirstweekday(weekday)`

Sets the weekday (0 is Monday, 6 is Sunday) to start each week. The values **MONDAY**, **TUESDAY**, **WEDNESDAY**,

**THURSDAY**, **FRIDAY**, **SATURDAY**, and **SUNDAY** are provided for convenience. For example, to set the first weekday to Sunday:

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

`calendar.firstweekday()`

Returns the current setting for the weekday to start each week.

`calendar.isleap(year)`

Returns **True** if *year* is a leap year, otherwise **False**.

`calendar.leapdays(y1, y2)`

Returns the number of leap years in the range from *y1* to *y2* (exclusive), where *y1* and *y2* are years.

This function works for ranges spanning a century change.

`calendar.weekday(year, month, day)`

Returns the day of the week (0 is Monday) for *year* (1970–...), *month* (1–12), *day* (1–31).

`calendar.weekheader(n)`

Return a header containing abbreviated weekday names. *n* specifies the width in characters for one weekday.

`calendar.monthrange(year, month)`

Returns weekday of first day of the month and number of days in month, for the specified *year* and *month*.

`calendar.monthcalendar(year, month)`

Returns a matrix representing a month's calendar. Each row represents a week; days outside of the month are represented by zeros. Each week begins with Monday unless set by

`setfirstweekday()`.

`calendar.prmonth(theyear, themoth, w=0, l=0)`

Prints a month's calendar as returned by `month()`.

`calendar.month(theyear, themoth, w=0, l=0)`

Returns a month's calendar in a multi-line string using the `formatmonth()` of the `TextCalendar` class.

`calendar.prcal(year, w=0, l=0, c=6, m=3)`

Prints the calendar for an entire year as returned by `calendar()`.

`calendar.calendar(year, w=2, l=1, c=6, m=3)`

Returns a 3-column calendar for an entire year as a multi-line string using the `formatyear()` of the `TextCalendar` class.

`calendar.timegm(tuple)`

An unrelated but handy function that takes a time tuple such as returned by the `gmtime()` function in the `time` module, and returns the corresponding Unix timestamp value, assuming an epoch of 1970, and the POSIX encoding. In fact, `time.gmtime()` and `timegm()` are each others' inverse.

The `calendar` module exports the following data attributes:

`calendar.day_name`

An array that represents the days of the week in the current locale.

`calendar.day_abbr`

An array that represents the abbreviated days of the week in the current locale.

`calendar.month_name`

An array that represents the months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_name[0]` is the empty string.

`calendar.month_abbr`

An array that represents the abbreviated months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_abbr[0]` is the empty string.

`calendar.MONDAY`

`calendar.TUESDAY`

`calendar.WEDNESDAY`

`calendar.THURSDAY`

`calendar.FRIDAY`

`calendar.SATURDAY`

`calendar.SUNDAY`

Aliases for day numbers, where `MONDAY` is 0 and `SUNDAY` is 6.

Object-oriented interface to dates and times with similar functionality to the `time` module.

### Module `time`

Low-level time related functions.

# collections — Container datatypes

Source code: [Lib/collections/\\_init\\_.py](https://github.com/python/cpython/tree/3.11/Lib/collections/_init_.py) [https://github.com/python/cpython/tree/3.11/Lib/collections/\_init\_.py]

---

This module implements specialized container datatypes providing alternatives to Python's general purpose built-in containers, `dict`, `list`, `set`, and `tuple`.

`factory function` for creating tuple subclasses with named fields

`list-like` container with fast appends and pops on either end

`dict-like` class for creating a single view of multiple mappings

`dict` subclass for counting `hashable` objects

`dict` subclass that remembers the order entries were added

`dict` subclass that calls a factory function to supply missing values

`wrapper` around dictionary objects for easier `dict` subclassing

`wrapper` around list objects for easier list subclassing

`wrapper` around string objects for easier string subclassing

## ChainMap objects

*New in version 3.3.*

A `ChainMap` class is provided for quickly linking a number of mappings so they can be treated as a single unit. It is often much faster than creating a new dictionary and running multiple `update()` calls.

The class can be used to simulate nested scopes and is useful in templating.

```
class collections.ChainMap(*maps)
```

A `ChainMap` groups multiple dicts or other mappings

together to create a single, updateable view. If no *maps* are specified, a single empty dictionary is provided so that a new chain always has at least one mapping.

The underlying mappings are stored in a list. That list is public and can be accessed or updated using the *maps* attribute. There is no other state.

Lookups search the underlying mappings successively until a key is found. In contrast, writes, updates, and deletions only operate on the first mapping.

A **ChainMap** incorporates the underlying mappings by reference. So, if one of the underlying mappings gets updated, those changes will be reflected in **ChainMap**.

All of the usual dictionary methods are supported. In addition, there is a *maps* attribute, a method for creating new subcontexts, and a property for accessing all but the first mapping:

*maps*

A user updateable list of mappings. The list is ordered from first-searched to last-searched. It is the only stored state and can be modified to change which mappings are searched. The list should always contain at least one mapping.

*new\_child(m=None, \*\*kwargs)*

Returns a new **ChainMap** containing a new map followed by all of the maps in the current instance. If *m* is specified, it becomes the new map at the front of the list of mappings; if not specified, an empty dict is used, so that a call to `d.new_child()` is equivalent to: `ChainMap({}, *d.maps)`. If any keyword arguments are specified, they update passed map or new empty dict. This method is used for creating subcontexts that can be updated without altering values in any of the parent mappings.

*Changed in version 3.4:* The optional `m` parameter was added.

*Changed in version 3.10:* Keyword arguments support was added.

## parents

Property returning a new `ChainMap` containing all of the maps in the current instance except the first one. This is useful for skipping the first map in the search. Use cases are similar to those for the `nonlocal` keyword used in `nested scopes`. The use cases also parallel those for the built-in `super()` function. A reference to `d.parents` is equivalent to:  
`ChainMap(*d.maps[1:])`.

Note, the iteration order of a `ChainMap()` is determined by scanning the mappings last to first:

```
>>> baseline = {'music': 'bach', 'art': 'rembrandt'}
>>> adjustments = {'art': 'van gogh', 'opera': 'car'}
>>> list(ChainMap(adjustments, baseline))
['music', 'art', 'opera']
```

This gives the same ordering as a series of `dict.update()` calls starting with the last mapping:

```
>>> combined = baseline.copy()
>>> combined.update(adjustments)
>>> list(combined)
['music', 'art', 'opera']
```

*Changed in version 3.9:* Added support for `|` and `|=` operators, specified in [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/].

## ChainMap Examples and Recipes

This section shows various approaches to working with chained maps.

Example of simulating Python's internal lookup chain:

```
import builtins
pylookup = ChainMap(locals(), globals(), vars(builtins))
```

Example of letting user specified command-line arguments take precedence over environment variables which in turn take precedence over default values:

```
import os, argparse

defaults = {'color': 'red', 'user': 'guest'}

parser = argparse.ArgumentParser()
parser.add_argument('-u', '--user')
parser.add_argument('-c', '--color')
namespace = parser.parse_args()
command_line_args = {k: v for k, v in vars(namespace).items() if v}
```

```
combined = ChainMap(command_line_args, os.environ, default_environ)
print(combined['color'])
print(combined['user'])
```

Example patterns for using the **ChainMap** class to simulate nested contexts:

```
c = ChainMap()           # Create root context
d = c.new_child()        # Create nested child context
e = c.new_child()        # Child of c, independent from d
e.maps[0]                # Current context dictionary -- like Python's globals
e.maps[-1]               # Root context -- like Python's globals
e.parents                # Enclosing context chain -- like Python's sys.argv

d['x'] = 1                # Set value in current context
d['x']                   # Get first key in the chain of contexts
del d['x']                # Delete from current context
list(d)                  # All nested values
k in d                   # Check all nested values
len(d)                   # Number of nested values
d.items()                # All nested items
dict(d)                  # Flatten into a regular dictionary
```

The **ChainMap** class only makes updates (writes and deletions) to the first mapping in the chain while lookups will search the full chain. However, if deep writes and deletions are desired, it is easy to make a subclass that updates keys found deeper in the chain:

```
class DeepChainMap(ChainMap):
    'Variant of ChainMap that allows direct updates to any mapping in the chain'

    def __setitem__(self, key, value):
        for mapping in self.maps:
            if key in mapping:
                mapping[key] = value
                return
        self.maps[0][key] = value

    def __delitem__(self, key):
```

```

        for mapping in self.maps:
            if key in mapping:
                del mapping[key]
            return
        raise KeyError(key)

>>> d = DeepChainMap({'zebra': 'black'}, {'elephant': 'black'})
>>> d['lion'] = 'orange'           # update an existing key
>>> d['snake'] = 'red'             # new keys get added to chain
>>> del d['elephant']              # remove an existing key
>>> d                             # display result
DeepChainMap({'zebra': 'black', 'snake': 'red'}, {}, {'lion': 'orange'})

```

## Counter objects

A counter tool is provided to support convenient and rapid tallies. For example:

```

>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue',
...             cnt[word] += 1
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669),
 ('you', 554), ('a', 546), ('my', 514), ('hamlet', 471)]

```

*class collections.Counter([iterable-or-mapping])*

A **Counter** is a **dict** subclass for counting **hashable** objects. It is a collection where elements are stored as dictionary keys and their counts are stored as dictionary values. Counts are allowed to be any integer value including zero or negative counts. The **Counter** class is similar to bags

or multisets in other languages.

Elements are counted from an *iterable* or initialized from another *mapping* (or counter):

```
>>> c = Counter() # a new
>>> c = Counter('gallahad') # a new
>>> c = Counter({'red': 4, 'blue': 2}) # a new
>>> c = Counter(cats=4, dogs=8) # a new
```

Counter objects have a dictionary interface except that they return a zero count for missing items instead of raising a **KeyError**:

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon'] # count
0
```

Setting a count to zero does not remove an element from a counter. Use `del` to remove it entirely:

```
>>> c['sausage'] = 0 # count
>>> del c['sausage'] # del a
```

*New in version 3.1.*

*Changed in version 3.7:* As a **dict** subclass, **Counter** inherited the capability to remember insertion order. Math operations on *Counter* objects also preserve order. Results are ordered according to when an element is first encountered in the left operand and then by the order encountered in the right operand.

Counter objects support additional methods beyond those available for all dictionaries:

**elements()**

Return an iterator over elements repeating each as many times as its count. Elements are returned in the order first encountered. If an element's count is less than one, **elements()** will ignore it.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> sorted(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

`most_common([n])`

Return a list of the *n* most common elements and their counts from the most common to the least. If *n* is omitted or `None`, `most_common()` returns *all* elements in the counter. Elements with equal counts are ordered in the order first encountered:

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('b', 2), ('r', 2)]
```

`subtract([iterable-or-mapping])`

Elements are subtracted from an *iterable* or from another *mapping* (or counter). Like `dict.update()` but subtracts counts instead of replacing them. Both inputs and outputs may be zero or negative.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

*New in version 3.2.*

`total()`

Compute the sum of the counts.

```
>>> c = Counter(a=10, b=5, c=0)
>>> c.total()
15
```

*New in version 3.10.*

The usual dictionary methods are available for `Counter`

objects except for two which work differently for counters.

`fromkeys(iterable)`

This class method is not implemented for **Counter** objects.

`update([iterable-or-mapping])`

Elements are counted from an *iterable* or added-in from another *mapping* (or counter). Like `dict.update()` but adds counts instead of replacing them. Also, the *iterable* is expected to be a sequence of elements, not a sequence of (key, value) pairs.

Counters support rich comparison operators for equality, subset, and superset relationships: `==`, `!=`, `<`, `<=`, `>`, `>=`. All of those tests treat missing elements as having zero counts so that `Counter(a=1) == Counter(a=1, b=0)` returns `true`.

*New in version 3.10:* Rich comparison operations were added.

*Changed in version 3.10:* In equality tests, missing elements are treated as having zero counts. Formerly, `Counter(a=3)` and `Counter(a=3, b=0)` were considered distinct.

Common patterns for working with **Counter** objects:

|                                           |                                                                       |
|-------------------------------------------|-----------------------------------------------------------------------|
| <code>c.total()</code>                    | <code># total of all counts</code>                                    |
| <code>c.clear()</code>                    | <code># reset all counts</code>                                       |
| <code>list(c)</code>                      | <code># list unique elements</code>                                   |
| <code>set(c)</code>                       | <code># convert to a set</code>                                       |
| <code>dict(c)</code>                      | <code># convert to a regular dict</code>                              |
| <code>c.items()</code>                    | <code># convert to a list of (key, value) pairs</code>                |
| <code>Counter(dict(list_of_pairs))</code> | <code># convert from a list of (key, value) pairs to a Counter</code> |
| <code>c.most_common()[:n-1:-1]</code>     | <code># n least common elements</code>                                |
| <code>+c</code>                           | <code># remove zero and negative counts</code>                        |

Several mathematical operations are provided for combining **Counter** objects to produce multisets (counters that have counts greater than zero). Addition and subtraction combine counters by

adding or subtracting the counts of corresponding elements. Intersection and union return the minimum and maximum of corresponding counts. Equality and inclusion compare corresponding counts. Each operation can accept inputs with signed counts, but the output will exclude results with counts of zero or less.

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                                     # add two counters together
Counter({'a': 4, 'b': 3})
>>> c - d                                     # subtract (keeping only)
Counter({'a': 2})
>>> c & d                                     # intersection: min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d                                     # union: max(c[x], d[x])
Counter({'a': 3, 'b': 2})
>>> c == d                                   # equality: c[x] == d[x]
False
>>> c <= d                                   # inclusion: c[x] <= d[x]
False
```

Unary addition and subtraction are shortcuts for adding an empty counter or subtracting from an empty counter.

```
>>> c = Counter(a=2, b=-4)
>>> +c
Counter({'a': 2})
>>> -c
Counter({'b': 4})
```

*New in version 3.3:* Added support for unary plus, unary minus, and in-place multiset operations.

## Note

Counters were primarily designed to work with positive integers to represent running counts; however, care was taken to not unnecessarily preclude use cases needing other types or negative values. To help with those use cases, this section documents the

minimum range and type restrictions.

- The `Counter` class itself is a dictionary subclass with no restrictions on its keys and values. The values are intended to be numbers representing counts, but you *could* store anything in the value field.
- The `most_common()` method requires only that the values be orderable.
- For in-place operations such as `c[key] += 1`, the value type need only support addition and subtraction. So fractions, floats, and decimals would work and negative values are supported. The same is also true for `update()` and `subtract()` which allow negative and zero values for both inputs and outputs.
- The multiset methods are designed only for use cases with positive values. The inputs may be negative or zero, but only outputs with positive values are created. There are no type restrictions, but the value type needs to support addition, subtraction, and comparison.
- The `elements()` method requires integer counts. It ignores zero and negative counts.

```
map(Counter, combinations_with_replacement('ABC',
```

## deque objects

```
class collections.deque([iterable[, maxlen]])
```

Returns a new deque object initialized left-to-right (using `append()`) with data from *iterable*. If *iterable* is not specified, the new deque is empty.

Deques are a generalization of stacks and queues (the name is pronounced “deck” and is short for “double-ended queue”). Deques support thread-safe, memory efficient appends and pops from either side of the deque with approximately the same  $O(1)$  performance in either direction.

Though `list` objects support similar operations, they are optimized for fast fixed-length operations and incur  $O(n)$  memory movement costs for `pop(0)` and `insert(0, v)` operations which change both the size and position of the underlying data representation.

If *maxlen* is not specified or is `None`, deques may grow to an arbitrary length. Otherwise, the deque is bounded to the specified maximum length. Once a bounded length deque is full, when new items are added, a corresponding number of items are discarded from the opposite end. Bounded length deques provide functionality similar to the `tail` filter in Unix. They are also useful for tracking transactions and other pools of data where only the most recent activity is of interest.

Deque objects support the following methods:

`append(x)`

Add *x* to the right side of the deque.

`appendleft(x)`

Add *x* to the left side of the deque.

`clear()`

Remove all elements from the deque leaving it with length 0.

`copy()`

Create a shallow copy of the deque.

*New in version 3.5.*

`count(x)`

Count the number of deque elements equal to *x*.

*New in version 3.2.*

`extend(iterable)`

Extend the right side of the deque by appending elements from the iterable argument.

`extendleft(iterable)`

Extend the left side of the deque by appending elements from *iterable*. Note, the series of left appends results in reversing the order of elements in the iterable argument.

`index(x[, start[, stop]])`

Return the position of *x* in the deque (at or after index *start* and before index *stop*). Returns the first match or raises **ValueError** if not found.

*New in version 3.5.*

`insert(i, x)`

Insert *x* into the deque at position *i*.

If the insertion would cause a bounded deque to grow beyond *maxlen*, an **IndexError** is raised.

*New in version 3.5.*

`pop()`

Remove and return an element from the right side of the deque. If no elements are present, raises an `IndexError`.

`popleft()`

Remove and return an element from the left side of the deque. If no elements are present, raises an `IndexError`.

`remove(value)`

Remove the first occurrence of *value*. If not found, raises a `ValueError`.

`reverse()`

Reverse the elements of the deque in-place and then return `None`.

*New in version 3.2.*

`rotate(n = 1)`

Rotate the deque *n* steps to the right. If *n* is negative, rotate to the left.

When the deque is not empty, rotating one step to the right is equivalent to `d.appendleft(d.pop())`, and rotating one step to the left is equivalent to `d.append(d.popleft())`.

Deque objects also provide one read-only attribute:

`maxlen`

Maximum size of a deque or `None` if unbounded.

*New in version 3.1.*

In addition to the above, deques support iteration, pickling, `len(d)`, `reversed(d)`, `copy.copy(d)`, `copy.deepcopy(d)`, membership testing with the `in` operator, and subscript references such as `d[0]` to access the first element. Indexed access is  $O(1)$  at both ends but slows to  $O(n)$  in the middle. For fast random access, use lists instead.

Starting in version 3.5, deques support `__add__()`, `__mul__()`, and `__imul__()`.

Example:

```
>>> from collections import deque
>>> d = deque('ghi')                # make a new deque
>>> for elem in d:                  # iterate over the
...     print(elem.upper())
G
H
I

>>> d.append('j')                   # add a new entry to the right
>>> d.appendleft('f')               # add a new entry to the left
>>> d                               # show the representation
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                         # return and remove the rightmost
'j'
>>> d.popleft()                     # return and remove the leftmost
'f'
>>> list(d)                         # list the contents
['g', 'h', 'i']
>>> d[0]                            # peek at leftmost
'g'
>>> d[-1]                           # peek at rightmost
'i'

>>> list(reversed(d))               # list the contents in reverse
['i', 'h', 'g']
>>> 'h' in d                        # search the deque
```

```

True
>>> d.extend('jkl')                # add multiple elements
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)                     # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)                    # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))               # make a new deque
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                       # empty the deque
>>> d.pop()                         # cannot pop from an empty deque
Traceback (most recent call last):
  File "<pyshell#6>", line 1, in <module>
    d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc')              # extendleft() reverses order
>>> d
deque(['c', 'b', 'a'])

```

## deque Recipes

This section shows various approaches to working with deques.

Bounded length deques provide functionality similar to the `tail` filter in Unix:

```

def tail(filename, n=10):
    'Return the last n lines of a file'
    with open(filename) as f:
        return deque(f, n)

```

Another approach to using deques is to maintain a sequence of recently added elements by appending to the right and popping to the left:

```
def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0
    # https://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / n
```

A [round-robin scheduler](https://en.wikipedia.org/wiki/Round-robin_scheduling) [https://en.wikipedia.org/wiki/Round-robin\_scheduling] can be implemented with input iterators stored in a [deque](#). Values are yielded from the active iterator in position zero. If that iterator is exhausted, it can be removed with [popleft\(\)](#); otherwise, it can be cycled back to the end with the [rotate\(\)](#) method:

```
def roundrobin(*iterables):
    "roundrobin('ABC', 'D', 'EF') --> A D E B F C"
    iterators = deque(map(iter, iterables))
    while iterators:
        try:
            while True:
                yield next(iterators[0])
                iterators.rotate(-1)
        except StopIteration:
            # Remove an exhausted iterator.
            iterators.popleft()
```

The [rotate\(\)](#) method provides a way to implement [deque](#) slicing and deletion. For example, a pure Python implementation of `del d[n]` relies on the `rotate()` method to position elements to be popped:

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

To implement **deque** slicing, use a similar approach applying **rotate()** to bring a target element to the left side of the deque. Remove old entries with **popleft()**, add new entries with **extend()**, and then reverse the rotation. With minor variations on that approach, it is easy to implement Forth style stack manipulations such as **dup**, **drop**, **swap**, **over**, **pick**, **rot**, and **roll**.

## defaultdict objects

*class collections.defaultdict(**default\_factory**=None, /[, ...])*

Return a new dictionary-like object. **defaultdict** is a subclass of the built-in **dict** class. It overrides one method and adds one writable instance variable. The remaining functionality is the same as for the **dict** class and is not documented here.

The first argument provides the initial value for the **default\_factory** attribute; it defaults to **None**. All remaining arguments are treated the same as if they were passed to the **dict** constructor, including keyword arguments.

**defaultdict** objects support the following method in addition to the standard **dict** operations:

**\_missing\_(key)**

If the **default\_factory** attribute is **None**, this raises a **KeyError** exception with the **key** as argument.

If **default\_factory** is not **None**, it is called without arguments to provide a default value for the given **key**, this value is inserted in the dictionary for the **key**, and returned.

If calling **default\_factory** raises an exception this exception is propagated unchanged.

This method is called by the `__getitem__()` method of the `dict` class when the requested key is not found; whatever it returns or raises is then returned or raised by `__getitem__()`.

Note that `__missing__()` is *not* called for any operations besides `__getitem__()`. This means that `get()` will, like normal dictionaries, return `None` as a default rather than using `default_factory`.

`defaultdict` objects support the following instance variable:

`default_factory`

This attribute is used by the `__missing__()` method; it is initialized from the first argument to the constructor, if present, or to `None`, if absent.

*Changed in version 3.9:* Added `merge(|)` and `update(|=)` operators, specified in [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/].

## `defaultdict` Examples

Using `list` as the `default_factory`, it is easy to group a sequence of key-value pairs into a dictionary of lists:

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

When each key is encountered for the first time, it is not already in the mapping; so an entry is automatically created using the `default_factory` function which returns an empty `list`. The `list.append()` operation then attaches the value to the new list. When keys are encountered again, the look-up proceeds normally

(returning the list for that key) and the `list.append()` operation adds another value to the list. This technique is simpler and faster than an equivalent technique using `dict.setdefault()`:

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

Setting the `default_factory` to `int` makes the `defaultdict` useful for counting (like a bag or multiset in other languages):

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> sorted(d.items())
[('i', 4), ('m', 1), ('p', 2), ('s', 4)]
```

When a letter is first encountered, it is missing from the mapping, so the `default_factory` function calls `int()` to supply a default count of zero. The increment operation then builds up the count for each letter.

The function `int()` which always returns zero is just a special case of constant functions. A faster and more flexible way to create constant functions is to use a lambda function which can supply any constant value (not just zero):

```
>>> def constant_factory(value):
...     return lambda: value
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

Setting the `default_factory` to `set` makes the `defaultdict`

useful for building a dictionary of sets:

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> sorted(d.items())
[('blue', {2, 4}), ('red', {1, 3})]
```

## **namedtuple()** Factory Function for Tuples with Named Fields

Named tuples assign meaning to each position in a tuple and allow for more readable, self-documenting code. They can be used wherever regular tuples are used, and they add the ability to access fields by name instead of position index.

`collections.namedtuple(typename, field_names, *, rename=False, defaults=None, module=None)`

Returns a new tuple subclass named *typename*. The new subclass is used to create tuple-like objects that have fields accessible by attribute lookup as well as being indexable and iterable. Instances of the subclass also have a helpful docstring (with *typename* and *field\_names*) and a helpful `__repr__()` method which lists the tuple contents in a `name=value` format.

The *field\_names* are a sequence of strings such as `['x', 'y']`. Alternatively, *field\_names* can be a single string with each fieldname separated by whitespace and/or commas, for example `'x y'` or `'x, y'`.

Any valid Python identifier may be used for a fieldname except for names starting with an underscore. Valid identifiers consist of letters, digits, and underscores but do not start with a digit or underscore and cannot be a **keyword** such as *class*, *for*, *return*, *global*, *pass*, or *raise*.

If *rename* is true, invalid fieldnames are automatically replaced with positional names. For example, `['abc', 'def', 'ghi', 'abc']` is converted to `['abc', '_1', 'ghi', '_3']`, eliminating the keyword `def` and the duplicate fieldname `abc`.

*defaults* can be `None` or an [iterable](#) of default values. Since fields with a default value must come after any fields without a default, the *defaults* are applied to the rightmost parameters. For example, if the fieldnames are `['x', 'y', 'z']` and the defaults are `(1, 2)`, then `x` will be a required argument, `y` will default to `1`, and `z` will default to `2`.

If *module* is defined, the `__module__` attribute of the named tuple is set to that value.

Named tuple instances do not have per-instance dictionaries, so they are lightweight and require no more memory than regular tuples.

To support pickling, the named tuple class should be assigned to a variable that matches *typename*.

*Changed in version 3.1:* Added support for *rename*.

*Changed in version 3.6:* The *verbose* and *rename* parameters became [keyword-only arguments](#).

*Changed in version 3.6:* Added the *module* parameter.

*Changed in version 3.7:* Removed the *verbose* parameter and the `__source` attribute.

*Changed in version 3.7:* Added the *defaults* parameter and the `__field_defaults` attribute.

```
>>> # Basic example
>>> Point = namedtuple('Point', ['x', 'y'])
>>> p = Point(11, y=22)           # instantiate with positional
>>> p[0] + p[1]                   # indexable like the plain tuple
33
```

```
>>> x, y = p                # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y              # fields also accessible by
33
>>> p                      # readable __repr__ with a r
Point(x=11, y=22)
```

Named tuples are especially useful for assigning field names to result tuples returned by the **csv** or **sqlite3** modules:

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, pay')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "r"))):
    print(emp.name, emp.title)

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, pay FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print(emp.name, emp.title)
```

In addition to the methods inherited from tuples, named tuples support three additional methods and two attributes. To prevent conflicts with field names, the method and attribute names start with an underscore.

*classmethod* `somenamedtuple._make(iterable)`

Class method that makes a new instance from an existing sequence or iterable.

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

`somenamedtuple._asdict()`

Return a new **dict** which maps field names to their

corresponding values:

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
{'x': 11, 'y': 22}
```

*Changed in version 3.1:* Returns an **OrderedDict** instead of a regular **dict**.

*Changed in version 3.8:* Returns a regular **dict** instead of an **OrderedDict**. As of Python 3.7, regular dicts are guaranteed to be ordered. If the extra features of **OrderedDict** are required, the suggested remediation is to cast the result to the desired type: `OrderedDict(nt._asdict())`.

**somenamedtuple.\_replace(\*\*kwargs)**

Return a new instance of the named tuple replacing specified fields with new values:

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)
```

```
>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=
```

**somenamedtuple.\_fields**

Tuple of strings listing the field names. Useful for introspection and for creating new named tuple types from existing named tuples.

```
>>> p._fields                # view the field names
('x', 'y')
```

```
>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Col
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

somenamedtuple.\_field\_defaults

Dictionary mapping field names to default values.

```
>>> Account = namedtuple('Account', ['type', 'balance'])
>>> Account._field_defaults
{'balance': 0}
>>> Account('premium')
Account(type='premium', balance=0)
```

To retrieve a field whose name is stored in a string, use the `getattr()` function:

```
>>> getattr(p, 'x')
11
```

To convert a dictionary to a named tuple, use the double-star-operator (as described in [Unpacking Argument Lists](#)):

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

Since a named tuple is a regular Python class, it is easy to add or change functionality with a subclass. Here is how to add a calculated field and a fixed-width print format:

```
>>> class Point(namedtuple('Point', ['x', 'y'])):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f  y=%6.3f  hypot=%6.3f'

>>> for p in Point(3, 4), Point(14, 5/7):
...     print(p)
Point: x= 3.000  y= 4.000  hypot= 5.000
Point: x=14.000  y= 0.714  hypot=14.018
```

The subclass shown above sets `__slots__` to an empty tuple. This

helps keep memory requirements low by preventing the creation of instance dictionaries.

Subclassing is not useful for adding new, stored fields. Instead, simply create a new named tuple type from the `__fields__` attribute:

```
>>> Point3D = namedtuple('Point3D', Point.__fields__ + ('z',))
```

Docstrings can be customized by making direct assignments to the `__doc__` fields:

```
>>> Book = namedtuple('Book', ['id', 'title', 'authors'])
>>> Book.__doc__ += ': Hardcover book in active collection'
>>> Book.id.__doc__ = '13-digit ISBN'
>>> Book.title.__doc__ = 'Title of first printing'
>>> Book.authors.__doc__ = 'List of authors sorted by last name'
```

*Changed in version 3.5:* Property docstrings became writeable.

## See also

- See `typing.NamedTuple` for a way to add type hints for named tuples. It also provides an elegant notation using the `class` keyword:

```
class Component(NamedTuple):
    part_number: int
    weight: float
    description: Optional[str] = None
```

- See `types.SimpleNamespace()` for a mutable namespace based on an underlying dictionary instead of a tuple.
- The `dataclasses` module provides a decorator and functions for automatically adding generated special methods to user-defined classes.

## OrderedDict objects

Ordered dictionaries are just like regular dictionaries but have some extra capabilities relating to ordering operations. They have become less important now that the built-in `dict` class gained the ability to remember insertion order (this new behavior became guaranteed in Python 3.7).

Some differences from `dict` still remain:

- The regular `dict` was designed to be very good at mapping operations. Tracking insertion order was secondary.
- The `OrderedDict` was designed to be good at reordering operations. Space efficiency, iteration speed, and the performance of update operations were secondary.
- The `OrderedDict` algorithm can handle frequent reordering operations better than `dict`. As shown in the recipes below, this makes it suitable for implementing various kinds of LRU caches.
- The equality operation for `OrderedDict` checks for matching order.

A regular `dict` can emulate the order sensitive equality test with `p == q` and `all(k1 == k2 for k1, k2 in zip(p, q))`.

- The `popitem()` method of `OrderedDict` has a different signature. It accepts an optional argument to specify which item is popped.

A regular `dict` can emulate `OrderedDict`'s `od.popitem(last=True)` with `d.popitem()` which is guaranteed to pop the rightmost (last) item.

A regular `dict` can emulate `OrderedDict`'s `od.popitem(last=False)` with `(k := next(iter(d)), d.pop(k))` which will return and remove the leftmost (first) item if it exists.

- `OrderedDict` has a `move_to_end()` method to efficiently reposition an element to an endpoint.

A regular `dict` can emulate `OrderedDict`'s `od.move_to_end(k, last=True)` with `d[k] = d.pop(k)` which will move the key and its associated value to the rightmost (last) position.

A regular `dict` does not have an efficient equivalent for `OrderedDict`'s `od.move_to_end(k, last=False)` which moves the key and its associated value to the leftmost (first) position.

- Until Python 3.8, `dict` lacked a `__reversed__()` method.

*class* `collections.OrderedDict([items])`

Return an instance of a `dict` subclass that has methods specialized for rearranging dictionary order.

*New in version 3.1.*

`popitem(last=True)`

The `popitem()` method for ordered dictionaries returns and removes a (key, value) pair. The pairs are returned in LIFO order if `last` is true or FIFO order if false.

`move_to_end(key, last=True)`

Move an existing `key` to either end of an ordered dictionary. The item is moved to the right end if `last` is true (the default) or to the beginning if `last` is false. Raises `KeyError` if the `key` does not exist:

```
>>> d = OrderedDict.fromkeys('abcde')
>>> d.move_to_end('b')
>>> ''.join(d)
'acdeb'
>>> d.move_to_end('b', last=False)
>>> ''.join(d)
'bacde'
```

*New in version 3.2.*

In addition to the usual mapping methods, ordered dictionaries also support reverse iteration using `reversed()`.

Equality tests between `OrderedDict` objects are order-sensitive and are implemented as

`list(od1.items()) == list(od2.items())`. Equality tests between `OrderedDict` objects and other `Mapping` objects are order-insensitive like regular dictionaries. This allows `OrderedDict` objects to be substituted anywhere a regular dictionary is used.

*Changed in version 3.5:* The items, keys, and values `views` of `OrderedDict` now support reverse iteration using `reversed()`.

*Changed in version 3.6:* With the acceptance of [PEP 468](https://peps.python.org/pep-0468/) [https://peps.python.org/pep-0468/], order is retained for keyword arguments passed to the `OrderedDict` constructor and its `update()` method.

*Changed in version 3.9:* Added `merge(|)` and `update(|=)` operators, specified in [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/].

## `OrderedDict` Examples and Recipes

It is straightforward to create an ordered dictionary variant that remembers the order the keys were *last* inserted. If a new entry overwrites an existing entry, the original insertion position is changed and moved to the end:

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        super().__setitem__(key, value)
        self.move_to_end(key)
```

An `OrderedDict` would also be useful for implementing variants of `functools.lru_cache()`:

```
from time import time
```

```

class TimeBoundedLRU:
    "LRU Cache that invalidates and refreshes old entries"

    def __init__(self, func, maxsize=128, maxage=30):
        self.cache = OrderedDict()      # { args : (time, result) }
        self.func = func
        self.maxsize = maxsize
        self.maxage = maxage

    def __call__(self, *args):
        if args in self.cache:
            self.cache.move_to_end(args)
            timestamp, result = self.cache[args]
            if time() - timestamp <= self.maxage:
                return result
        result = self.func(*args)
        self.cache[args] = time(), result
        if len(self.cache) > self.maxsize:
            self.cache.popitem(0)
        return result

class MultiHitLRUCache:
    """ LRU cache that defers caching a result until
        it has been requested multiple times.

        To avoid flushing the LRU cache with one-time requests
        we don't cache until a request has been made more than
        once.

    """

    def __init__(self, func, maxsize=128, maxrequests=40):
        self.requests = OrderedDict()    # { uncached_key : count }
        self.cache = OrderedDict()       # { cached_key : result }
        self.func = func
        self.maxrequests = maxrequests    # max number of requests
        self.maxsize = maxsize            # max number of items
        self.cache_after = cache_after

    def __call__(self, *args):

```

```

    if args in self.cache:
        self.cache.move_to_end(args)
        return self.cache[args]
    result = self.func(*args)
    self.requests[args] = self.requests.get(args, 0)
    if self.requests[args] <= self.cache_after:
        self.requests.move_to_end(args)
        if len(self.requests) > self.maxrequests:
            self.requests.popitem(0)
    else:
        self.requests.pop(args, None)
        self.cache[args] = result
        if len(self.cache) > self.maxsize:
            self.cache.popitem(0)
    return result

```

## UserDict objects

The class, **UserDict** acts as a wrapper around dictionary objects. The need for this class has been partially supplanted by the ability to subclass directly from **dict**; however, this class can be easier to work with because the underlying dictionary is accessible as an attribute.

*class collections.UserDict([initialdata])*

Class that simulates a dictionary. The instance's contents are kept in a regular dictionary, which is accessible via the **data** attribute of **UserDict** instances. If *initialdata* is provided, **data** is initialized with its contents; note that a reference to *initialdata* will not be kept, allowing it to be used for other purposes.

In addition to supporting the methods and operations of mappings, **UserDict** instances provide the following attribute:

**data**

A real dictionary used to store the contents of the **UserDict** class.

## UserList objects

This class acts as a wrapper around list objects. It is a useful base class for your own list-like classes which can inherit from them and override existing methods or add new ones. In this way, one can add new behaviors to lists.

The need for this class has been partially supplanted by the ability to subclass directly from `list`; however, this class can be easier to work with because the underlying list is accessible as an attribute.

*class collections.UserList([list])*

Class that simulates a list. The instance's contents are kept in a regular list, which is accessible via the `data` attribute of `UserList` instances. The instance's contents are initially set to a copy of `list`, defaulting to the empty list `[]`. `list` can be any iterable, for example a real Python list or a `UserList` object.

In addition to supporting the methods and operations of mutable sequences, `UserList` instances provide the following attribute:

`data`

A real `list` object used to store the contents of the `UserList` class.

**Subclassing requirements:** Subclasses of `UserList` are expected to offer a constructor which can be called with either no arguments or one argument. List operations which return a new sequence attempt to create an instance of the actual implementation class. To do so, it assumes that the constructor can be called with a single parameter, which is a sequence object used as a data source.

If a derived class does not wish to comply with this requirement, all of the special methods supported by this class will need to be overridden; please consult the sources for information about the methods which need to be provided in that case.

## UserString objects

The class, `UserString` acts as a wrapper around string objects. The need for this class has been partially supplanted by the ability to subclass directly from `str`; however, this class can be easier to work with because the underlying string is accessible as an attribute.

*class* collections.UserString(*seq*)

Class that simulates a string object. The instance's content is kept in a regular string object, which is accessible via the `data` attribute of `UserString` instances. The instance's contents are initially set to a copy of *seq*. The *seq* argument can be any object which can be converted into a string using the built-in `str()` function.

In addition to supporting the methods and operations of strings, `UserString` instances provide the following attribute:

`data`

A real `str` object used to store the contents of the `UserString` class.

*Changed in version 3.5:* New methods `__getnewargs__`, `__rmod__`, `casefold`, `format_map`, `isprintable`, and `maketrans`.

# `collections.abc` — Abstract Base Classes for Containers

*New in version 3.3:* Formerly, this module was part of the `collections` module.

**Source code:** [Lib/\\_collections\\_abc.py](https://github.com/python/cpython/tree/3.11/Lib/_collections_abc.py) [https://github.com/python/cpython/tree/3.11/Lib/\_collections\_abc.py]

---

This module provides [abstract base classes](#) that can be used to test whether a class provides a particular interface; for example, whether it is [hashable](#) or whether it is a mapping.

An `issubclass()` or `isinstance()` test for an interface works in one of three ways.

1) A newly written class can inherit directly from one of the abstract base classes. The class must supply the required abstract methods. The remaining mixin methods come from inheritance and can be overridden if desired. Other methods may be added as needed:

```
class C(Sequence):
    def __init__(self): ...
    def __getitem__(self, index): ...
    def __len__(self): ...
    def count(self, value): ...

>>> issubclass(C, Sequence)
True
>>> isinstance(C(), Sequence)
True
```

2) Existing classes and built-in classes can be registered as “virtual subclasses” of the ABCs. Those classes should define the full API

including all of the abstract methods and all of the mixin methods. This lets users rely on `issubclass()` or `isinstance()` tests to determine whether the full interface is supported. The exception to this rule is for methods that are automatically inferred from the rest of the API:

```
class D:                                # No inheritance
    def __init__(self): ...              # Extra method
    def __getitem__(self, index): ...     # Abstract method
    def __len__(self): ...               # Abstract method
    def count(self, value): ...           # Mixin method
    def index(self, value): ...           # Mixin method

Sequence.register(D)                    # Register instance
```

```
>>> issubclass(D, Sequence)
True
>>> isinstance(D(), Sequence)
True
```

In this example, class `D` does not need to define `__contains__`, `__iter__`, and `__reversed__` because the [in-operator](#), the [iteration](#) logic, and the [reversed\(\)](#) function automatically fall back to using `__getitem__` and `__len__`.

3) Some simple interfaces are directly recognizable by the presence of the required methods (unless those methods have been set to [None](#)):

```
class E:
    def __iter__(self): ...
    def __next__(next): ...

>>> issubclass(E, Iterable)
True
>>> isinstance(E(), Iterable)
True
```

Complex interfaces do not support this last technique because an interface is more than just the presence of method names. Interfaces

specify semantics and relationships between methods that cannot be inferred solely from the presence of specific method names. For example, knowing that a class supplies `__getitem__`, `__len__`, and `__iter__` is insufficient for distinguishing a **Sequence** from a **Mapping**.

*New in version 3.9:* These abstract classes now support `[]`. See **Generic Alias Type** and **PEP 585** [<https://peps.python.org/pep-0585/>].

## Collections Abstract Base Classes

The collections module offers the following **ABCs**:

### Minimal Methods

**Container**<sup>1</sup>

**Hashable**<sup>1</sup>

**Iterable**<sup>1 2</sup>

**Iterable**<sup>1</sup>

**Reversible**<sup>1</sup>

**Generator**<sup>1</sup> `__iter__`, `__next__`

**Sized**<sup>1</sup>

**Callable**<sup>1</sup>

**Container**, **Iterable**, **Container** `__len__`

**Reversible**, **Collection**, `__reversed__`, `index`, and `count`

**MutableSequence** methods and `__delitem__`, `__reversed__`, `extend`, `pop`, `remove`, and `__iadd__`

**MutableSequence** methods

**Set** `__delitem__`, `__iter__`, `__len__`, `__gt__`, `__ge__`, `__and__`, `__or__`, `__sub__`, `__xor__`, and `isdisjoint`

**MutableSet** methods and `clear`, `pop`, `remove`, `discard`, `__iand__`, `__ixor__`, and `__isub__`

**Mapping** `__getitem__`, `keys`, `items`, `values`, `get`, `__eq__`, and `__ne__`

**MutableMapping** methods and `pop`, `popitem`, `clear`, `update`, and `setdefault`

**MappingView**

**MappingView**, **Set** `__iter__`

**MappingView**, **Set** `__iter__`

**MappingView**, **Collection**

[Awaitable 1](#)

[Sendfile 1](#)

[AsyncIterable 1](#)

[AsyncIterator 1](#)

[AsyncIterator 1](#), `__anext__`

## Footnotes

1([1](#),[2](#),[3](#),[4](#),[5](#),[6](#),[7](#),[8](#),[9](#),[10](#),[11](#),[12](#),[13](#),[14](#))

These ABCs override `object.__subclasshook__()` to support testing an interface by verifying the required methods are present and have not been set to `None`. This only works for simple interfaces. More complex interfaces require registration or direct subclassing.

2

Checking `isinstance(obj, Iterable)` detects classes that are registered as `Iterable` or that have an `__iter__()` method, but it does not detect classes that iterate with the `__getitem__()` method. The only reliable way to determine whether an object is `iterable` is to call `iter(obj)`.

## Collections Abstract Base Classes – Detailed Descriptions

*class* `collections.abc.Container`

ABC for classes that provide the `__contains__()` method.

*class* `collections.abc.Hashable`

ABC for classes that provide the `__hash__()` method.

*class* `collections.abc.Sized`

ABC for classes that provide the `__len__()` method.

*class* `collections.abc.Callable`

ABC for classes that provide the `__call__()` method.

*class* collections.abc.Iterable

ABC for classes that provide the `__iter__()` method.

Checking `isinstance(obj, Iterable)` detects classes that are registered as `Iterable` or that have an `__iter__()` method, but it does not detect classes that iterate with the `__getitem__()` method. The only reliable way to determine whether an object is `iterable` is to call `iter(obj)`.

*class* collections.abc.Collection

ABC for sized iterable container classes.

*New in version 3.6.*

*class* collections.abc.Iterator

ABC for classes that provide the `__iter__()` and `__next__()` methods. See also the definition of `iterator`.

*class* collections.abc.Reversible

ABC for iterable classes that also provide the `__reversed__()` method.

*New in version 3.6.*

*class* collections.abc.Generator

ABC for generator classes that implement the protocol defined in [PEP 342](https://peps.python.org/pep-0342/) [https://peps.python.org/pep-0342/] that extends iterators with the `send()`, `throw()` and `close()` methods. See also the definition of `generator`.

*New in version 3.5.*

*class* collections.abc.Sequence

*class* collections.abc.MutableSequence

*class* collections.abc.ByteString

ABCs for read-only and mutable `sequences`.

Implementation note: Some of the mixin methods, such as

`__iter__()`, `__reversed__()` and `index()`, make repeated calls to the underlying `__getitem__()` method. Consequently, if `__getitem__()` is implemented with constant access speed, the mixin methods will have linear performance; however, if the underlying method is linear (as it would be with a linked list), the mixins will have quadratic performance and will likely need to be overridden.

*Changed in version 3.5:* The `index()` method added support for *stop* and *start* arguments.

```
class collections.abc.Set
class collections.abc.MutableSet
    ABCs for read-only and mutable sets.
```

```
class collections.abc.Mapping
class collections.abc.MutableMapping
    ABCs for read-only and mutable mappings.
```

```
class collections.abc.MappingView
class collections.abc.ItemsView
class collections.abc.KeysView
class collections.abc.ValuesView
    ABCs for mapping, items, keys, and values views.
```

```
class collections.abc.Awaitable
    ABC for awaitable objects, which can be used in await
    expressions. Custom implementations must provide the
    __await__() method.
```

[Coroutine](#) objects and instances of the [Coroutine](#) ABC are all instances of this ABC.

## Note

In CPython, generator-based coroutines (generators decorated with `types.coroutine()`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Awaitable)` for them

will return `False`. Use `inspect.isawaitable()` to detect them.

*New in version 3.5.*

*class* `collections.abc.Coroutine`

ABC for coroutine compatible classes. These implement the following methods, defined in [Coroutine Objects](#): `send()`, `throw()`, and `close()`. Custom implementations must also implement `__await__()`. All `Coroutine` instances are also instances of `Awaitable`. See also the definition of [coroutine](#).

### Note

In CPython, generator-based coroutines (generators decorated with `types.coroutine()`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Coroutine)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

*New in version 3.5.*

*class* `collections.abc.AsyncIterable`

ABC for classes that provide `__aiter__` method. See also the definition of [asynchronous iterable](#).

*New in version 3.5.*

*class* `collections.abc.AsyncIterator`

ABC for classes that provide `__aiter__` and `__anext__` methods. See also the definition of [asynchronous iterator](#).

*New in version 3.5.*

*class* `collections.abc.AsyncGenerator`

ABC for asynchronous generator classes that implement the

protocol defined in [PEP 525](https://peps.python.org/pep-0525/) [https://peps.python.org/pep-0525/] and [PEP 492](https://peps.python.org/pep-0492/) [https://peps.python.org/pep-0492/].

*New in version 3.6.*

## Examples and Recipes

ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```
size = None
if isinstance(myvar, collections.abc.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full [Set](#) API, it is only necessary to supply the three underlying abstract methods: `__contains__()`, `__iter__()`, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and `isdisjoint()`:

```
class ListBasedSet(collections.abc.Set):
    ''' Alternate set implementation favoring space over
        and not requiring the set elements to be hashable '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)
```

```
s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2                    # The __and__() method is s
```

Notes on using **Set** and **MutableSet** as a mixin:

1. Since some set operations create new sets, the default mixin methods need a way to create new instances from an iterable. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal classmethod called `__from_iterable()` which calls `cls(iterable)` to produce a new set. If the **Set** mixin is being used in a class with a different constructor signature, you will need to override `__from_iterable()` with a classmethod or regular method that can construct new instances from an iterable argument.
2. To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.
3. The **Set** mixin provides a `__hash__()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are **hashable** or immutable. To add set hashability using mixins, inherit from both **Set()** and **Hashable()**, then define `__hash__ = Set.__hash__`.

# heapq — Heap queue algorithm

**Source code:** [Lib/heapq.py](https://github.com/python/cpython/tree/3.11/Lib/heapq.py) [https://github.com/python/cpython/tree/3.11/Lib/heapq.py]

---

This module provides an implementation of the heap queue algorithm, also known as the priority queue algorithm.

Heaps are binary trees for which every parent node has a value less than or equal to any of its children. This implementation uses arrays for which  $\text{heap}[k] \leq \text{heap}[2*k+1]$  and  $\text{heap}[k] \leq \text{heap}[2*k+2]$  for all  $k$ , counting elements from zero. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that its smallest element is always the root,  $\text{heap}[0]$ .

The API below differs from textbook heap algorithms in two aspects: (a) We use zero-based indexing. This makes the relationship between the index for a node and the indexes for its children slightly less obvious, but is more suitable since Python uses zero-based indexing. (b) Our `pop` method returns the smallest item, not the largest (called a “min heap” in textbooks; a “max heap” is more common in texts because of its suitability for in-place sorting).

These two make it possible to view the heap as a regular Python list without surprises:  $\text{heap}[0]$  is the smallest item, and `heap.sort()` maintains the heap invariant!

To create a heap, use a list initialized to `[]`, or you can transform a populated list into a heap via function `heapify()`.

The following functions are provided:

`heapq.heappush(heap, item)`

Push the value *item* onto the *heap*, maintaining the heap invariant.

`heapq.heappop(heap)`

Pop and return the smallest item from the *heap*, maintaining the heap invariant. If the heap is empty, `IndexError` is raised. To access the smallest item without popping it, use `heap[0]`.

`heapq.heappushpop(heap, item)`

Push *item* on the heap, then pop and return the smallest item from the *heap*. The combined action runs more efficiently than `heappush()` followed by a separate call to `heappop()`.

`heapq.heapify(x)`

Transform list *x* into a heap, in-place, in linear time.

`heapq.heapreplace(heap, item)`

Pop and return the smallest item from the *heap*, and also push the new *item*. The heap size doesn't change. If the heap is empty, `IndexError` is raised.

This one step operation is more efficient than a `heappop()` followed by `heappush()` and can be more appropriate when using a fixed-size heap. The pop/push combination always returns an element from the heap and replaces it with *item*.

The value returned may be larger than the *item* added. If that isn't desired, consider using `heappushpop()` instead. Its push/pop combination returns the smaller of the two values, leaving the larger value on the heap.

The module also offers three general purpose functions based on heaps.

`heapq.merge(*iterables, key=None, reverse=False)`

Merge multiple sorted inputs into a single sorted output (for example, merge timestamped entries from multiple log files). Returns an [iterator](#) over the sorted values.

Similar to `sorted(itertools.chain(*iterables))` but returns an iterable, does not pull the data into memory all at once, and assumes that each of the input streams is already sorted (smallest to largest).

Has two optional arguments which must be specified as keyword arguments.

*key* specifies a [key function](#) of one argument that is used to extract a comparison key from each input element. The default value is `None` (compare the elements directly).

*reverse* is a boolean value. If set to `True`, then the input elements are merged as if each comparison were reversed. To achieve behavior similar to

`sorted(itertools.chain(*iterables), reverse=True)`, all iterables must be sorted from largest to smallest.

*Changed in version 3.5:* Added the optional *key* and *reverse* parameters.

`heapq.nlargest(n, iterable, key=None)`

Return a list with the *n* largest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key, reverse=True)[:n]`.

`heapq.nsmallest(n, iterable, key=None)`

Return a list with the *n* smallest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key)[:n]`.

The latter two functions perform best for smaller values of  $n$ . For larger values, it is more efficient to use the `sorted()` function. Also, when `n==1`, it is more efficient to use the built-in `min()` and `max()` functions. If repeated usage of these functions is required, consider turning the iterable into an actual heap.

## Basic Examples

A [heapsort](https://en.wikipedia.org/wiki/Heapsort) [https://en.wikipedia.org/wiki/Heapsort] can be implemented by pushing all values onto a heap and then popping off the smallest values one at a time:

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

This is similar to `sorted(iterable)`, but unlike `sorted()`, this implementation is not stable.

Heap elements can be tuples. This is useful for assigning comparison values (such as task priorities) alongside the main record being tracked:

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

## Priority Queue Implementation Notes

A [priority queue](https://en.wikipedia.org/wiki/Priority_queue) [https://en.wikipedia.org/wiki/Priority\_queue] is common

use for a heap, and it presents several implementation challenges:

- Sort stability: how do you get two tasks with equal priorities to be returned in the order they were originally added?
- Tuple comparison breaks for (priority, task) pairs if the priorities are equal and the tasks do not have a default comparison order.
- If the priority of a task changes, how do you move it to a new position in the heap?
- Or if a pending task needs to be deleted, how do you find it and remove it from the queue?

A solution to the first two challenges is to store entries as 3-element list including the priority, an entry count, and the task. The entry count serves as a tie-breaker so that two tasks with the same priority are returned in the order they were added. And since no two entry counts are the same, the tuple comparison will never attempt to directly compare two tasks.

Another solution to the problem of non-comparable tasks is to create a wrapper class that ignores the task item and only compares the priority field:

```
from dataclasses import dataclass, field
from typing import Any
```

```
@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

The remaining challenges revolve around finding a pending task and making changes to its priority or removing it entirely. Finding a task can be done with a dictionary pointing to an entry in the queue.

Removing the entry or changing its priority is more difficult because it would break the heap structure invariants. So, a possible solution is to mark the entry as removed and add a new entry with the revised priority:

```

pq = []                                # list of entries arranged in a heap
entry_finder = {}                      # mapping of tasks to entries
REMOVED = '<removed-task>'            # placeholder for a removed task
counter = itertools.count()            # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED.  Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
    'Remove and return the lowest priority task. Raise KeyError if empty'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
            del entry_finder[task]
            return task
    raise KeyError('pop from an empty priority queue')

```

## Theory

Heaps are arrays for which  $a[k] \leq a[2k+1]$  and  $a[k] \leq a[2k+2]$  for all  $k$ , counting elements from 0. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that  $a[0]$  is always its smallest element.

The strange invariant above is meant to be an efficient memory representation for a tournament. The numbers below are  $k$ , not

a[k]:

In the tree above, each cell  $k$  is topping  $2*k+1$  and  $2*k+2$ . In a usual binary tournament we see in sports, each cell is the winner over the two cells it tops, and we can trace the winner down the tree to see all opponents s/he had. However, in many computer applications of such tournaments, we do not need to trace the history of a winner. To be more memory efficient, when a winner is promoted, we try to replace it by something else at a lower level, and the rule becomes that a cell and the two cells it tops contain three different items, but the top cell “wins” over the two topped cells.

If this heap invariant is protected at all time, index 0 is clearly the overall winner. The simplest algorithmic way to remove it and find the “next” winner is to move some loser (let’s say cell 30 in the diagram above) into the 0 position, and then percolate this new 0 down the tree, exchanging values, until the invariant is re-established. This is clearly logarithmic on the total number of items in the tree. By iterating over all items, you get an  $O(n \log n)$  sort.

A nice feature of this sort is that you can efficiently insert new items while the sort is going on, provided that the inserted items are not “better” than the last 0’th element you extracted. This is especially useful in simulation contexts, where the tree holds all incoming events, and the “win” condition means the smallest scheduled time. When an event schedules other events for execution, they are scheduled into the future, so they can easily go into the heap. So, a heap is a good structure for implementing schedulers (this is what I used for my MIDI sequencer :-).

Various structures for implementing schedulers have been extensively studied, and heaps are good for this, as they are reasonably speedy, the speed is almost constant, and the worst case is not much different than the average case. However, there are other representations which are more efficient overall, yet the worst cases might be terrible.

Heaps are also very useful in big disk sorts. You most probably all know that a big sort implies producing “runs” (which are pre-sorted sequences, whose size is usually related to the amount of CPU memory), followed by a merging passes for these runs, which merging is often very cleverly organised <sup>1</sup>. It is very important that the initial sort produces the longest runs possible. Tournaments are a good way to achieve that. If, using all the memory available to hold a tournament, you replace and percolate items that happen to fit the current run, you’ll produce runs which are twice the size of the memory for random input, and much better for input fuzzily ordered.

Moreover, if you output the 0<sup>th</sup> item on disk and get an input which may not fit in the current tournament (because the value “wins” over the last output value), it cannot fit in the heap, so the size of the heap decreases. The freed memory could be cleverly reused immediately for progressively building a second heap, which grows at exactly the same rate the first heap is melting. When the first heap completely vanishes, you switch heaps and start a new run. Clever and quite effective!

In a word, heaps are useful memory structures to know. I use them in a few applications, and I think it is good to keep a ‘heap’ module around. :-)

## Footnotes

<sup>1</sup>

The disk balancing algorithms which are current, nowadays, are more annoying than clever, and this is a consequence of the seeking capabilities of the disks. On devices which cannot seek, like big tape drives, the story was quite different, and one had

to be very clever to ensure (far in advance) that each tape movement will be the most effective possible (that is, will best participate at “progressing” the merge). Some tapes were even able to read backwards, and this was also used to avoid the rewinding time. Believe me, real good tape sorts were quite spectacular to watch! From all times, sorting has always been a Great Art! :-)

# bisect — Array bisection algorithm

**Source code:** [Lib/bisect.py](https://github.com/python/cpython/tree/3.11/Lib/bisect.py) [https://github.com/python/cpython/tree/3.11/Lib/bisect.py]

---

This module provides support for maintaining a list in sorted order without having to sort the list after each insertion. For long lists of items with expensive comparison operations, this can be an improvement over the more common approach. The module is called **bisect** because it uses a basic bisection algorithm to do its work. The source code may be most useful as a working example of the algorithm (the boundary conditions are already right!).

The following functions are provided:

`bisect.bisect_left(a, x, lo=0, hi=len(a), *, key=None)`

Locate the insertion point for *x* in *a* to maintain sorted order. The parameters *lo* and *hi* may be used to specify a subset of the list which should be considered; by default the entire list is used. If *x* is already present in *a*, the insertion point will be before (to the left of) any existing entries. The return value is suitable for use as the first parameter to `list.insert()` assuming that *a* is already sorted.

The returned insertion point *i* partitions the array *a* into two halves so that `all(val < x for val in a[lo : i])` for the left side and `all(val >= x for val in a[i : hi])` for the right side.

*key* specifies a **key function** of one argument that is used to extract a comparison key from each element in the array. To support searching complex records, the key function is not applied to the *x* value.

If `key` is `None`, the elements are compared directly with no intervening function call.

*Changed in version 3.10:* Added the `key` parameter.

```
bisect.bisect_right(a, x, lo=0, hi=len(a), *, key=None)
```

```
bisect.bisect(a, x, lo=0, hi=len(a), *, key=None)
```

Similar to `bisect_left()`, but returns an insertion point which comes after (to the right of) any existing entries of `x` in `a`.

The returned insertion point `i` partitions the array `a` into two halves so that `all(val <= x for val in a[lo : i])` for the left side and `all(val > x for val in a[i : hi])` for the right side.

`key` specifies a [key function](#) of one argument that is used to extract a comparison key from each element in the array. To support searching complex records, the key function is not applied to the `x` value.

If `key` is `None`, the elements are compared directly with no intervening function call.

*Changed in version 3.10:* Added the `key` parameter.

```
bisect.insort_left(a, x, lo=0, hi=len(a), *, key=None)
```

Insert `x` in `a` in sorted order.

This function first runs `bisect_left()` to locate an insertion point. Next, it runs the `insert()` method on `a` to insert `x` at the appropriate position to maintain sort order.

To support inserting records in a table, the `key` function (if any) is applied to `x` for the search step but not for the insertion step.

Keep in mind that the  $O(\log n)$  search is dominated by the slow  $O(n)$  insertion step.

*Changed in version 3.10:* Added the *key* parameter.

```
bisect.insort_right(a, x, lo=0, hi=len(a), *, key=None)
```

```
bisect.insort(a, x, lo=0, hi=len(a), *, key=None)
```

Similar to `insort_left()`, but inserting *x* in *a* after any existing entries of *x*.

This function first runs `bisect_right()` to locate an insertion point. Next, it runs the `insert()` method on *a* to insert *x* at the appropriate position to maintain sort order.

To support inserting records in a table, the *key* function (if any) is applied to *x* for the search step but not for the insertion step.

Keep in mind that the  $O(\log n)$  search is dominated by the slow  $O(n)$  insertion step.

*Changed in version 3.10:* Added the *key* parameter.

## Performance Notes

When writing time sensitive code using `bisect()` and `insort()`, keep these thoughts in mind:

- Bisection is effective for searching ranges of values. For locating specific values, dictionaries are more performant.
- The `insort()` functions are  $O(n)$  because the logarithmic search step is dominated by the linear time insertion step.
- The search functions are stateless and discard key function results after they are used. Consequently, if the search functions are used in a loop, the key function may be called again and again on the same array elements. If the key function isn't fast, consider wrapping it with `functools.cache()` to avoid duplicate computations. Alternatively, consider searching an array of precomputed keys to locate the insertion point (as shown in the examples section below).

## See also

- [Sorted Collections](https://grantjenks.com/docs/sortedcollections/) [https://grantjenks.com/docs/sortedcollections/] is a high performance module that uses *bisect* to managed sorted collections of data.
- The [SortedCollection recipe](https://code.activestate.com/recipes/577197-sortedcollection/) [https://code.activestate.com/recipes/577197-sortedcollection/] uses *bisect* to build a full-featured collection class with straight-forward search methods and support for a key-function. The keys are precomputed to save unnecessary calls to the key function during searches.

## Searching Sorted Lists

The above [bisect functions](#) are useful for finding insertion points but can be tricky or awkward to use for common searching tasks. The following five functions show how to transform them into the standard lookups for sorted lists:

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):

    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

```

## Examples

The `bisect()` function can be useful for numeric table lookups. This example uses `bisect()` to look up a letter grade for an exam score (say) based on a set of ordered numeric breakpoints: 90 and up is an 'A', 80 to 89 is a 'B', and so on:

```

>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA')
...     i = bisect(breakpoints, score)
...     return grades[i]
...
>>> [grade(score) for score in [33, 99, 77, 70, 89, 90],
    ['F', 'A', 'C', 'C', 'B', 'A', 'A']]

```

The `bisect()` and `insort()` functions also work with lists of tuples. The `key` argument can serve to extract the field used for ordering records in a table:

```

>>> from collections import namedtuple
>>> from operator import attrgetter
>>> from bisect import bisect, insort
>>> from pprint import pprint

```

```

>>> Movie = namedtuple('Movie', ('name', 'released', 'director'))

>>> movies = [
...     Movie('Jaws', 1975, 'Spielberg'),
...     Movie('Titanic', 1997, 'Cameron'),
...     Movie('The Birds', 1963, 'Hitchcock'),
...     Movie('Aliens', 1986, 'Cameron')
... ]

>>> # Find the first movie released after 1960
>>> by_year = attrgetter('released')
>>> movies.sort(key=by_year)
>>> movies[bisect(movies, 1960, key=by_year)]
Movie(name='The Birds', released=1963, director='Hitchcock')

>>> # Insert a movie while maintaining sort order
>>> romance = Movie('Love Story', 1970, 'Hiller')
>>> insort(movies, romance, key=by_year)
>>> pprint(movies)
[Movie(name='The Birds', released=1963, director='Hitchcock'),
 Movie(name='Love Story', released=1970, director='Hiller'),
 Movie(name='Jaws', released=1975, director='Spielberg'),
 Movie(name='Aliens', released=1986, director='Cameron'),
 Movie(name='Titanic', released=1997, director='Cameron')]

```
